These schemes might be described as of the "old type," in that they do not necessarily make use of the newer methods of control. The new type, utilizing them as a matter of principle, was initiated in British Guiana, where Symes and Hadaway[6] carried out the experimental work; this was later enlarged by the Government into an executive scheme under the direction of Giglioli, who has since reported on its outcome.[7] Though the country is large, 90.5% of the 375,000 inhabitants are concentrated in a narrow waterlogged coastal strip infested by numerous mosquitoes, of which *A. darlingi* is the main malaria vector and *A. aquasalis* a minor one. No anti-larval measures have been used, entire reliance being placed on the use of D.D.T. residual indoor sprays at intervals of eight months. In the initial stages, when only a small proportion of houses were treated, no effect on breeding was seen, but when all houses came under treatment it was observed that control was so effective that the breeding of *A. darlingi* stopped, and this species is no longer present in the populated area. As this mosquito continues to exist in the neighbouring forest the risk of re-invasion is clearly great, and can be guarded against only by the continued treatment of the populated area. The annual cost of this work per head is $0.637. It has been brilliantly successful, but it must be remembered that conditions proved unusually favourable for a residual insecticide in that *A. darlingi* shelters exclusively in houses which are of a type peculiarly easy to treat.

In 1946 the Italian Health Commission, at the instigation of the U.N.R.R.A. Italian Mission, decided to attempt the eradication of all anophelines from Sardinia by the use of residual insecticides. This scheme has not yet been reported on officially. Conditions in Sardinia resemble those in Cyprus, except that the former is

larger. It is known that the attempt at eradication solely by residual insecticides has failed, and that the old methods of larval control as used in Cyprus have now been undertaken in addition to the new ones. It seems that success will probably be achieved, but at about 10 times the cost per head of the Cyprus work. (Press reports state that the governors of the two islands had an even-odds bet of 100 litres of wine on the results of their race. The odds on Cyprus should now lengthen.) A similar scheme has just been started in Mauritius, a highly malarious island which has had severe epidemics of malaria for the past 70 years and in which the disease is carried by *A. funestus*, with *A. gambiae* as a subsidiary vector. The intention of this scheme is to attempt eradication by the use of residual insecticides and to gain data applicable to other territories in the process; larvicides will be used as a supplement if there should be no early promise of success by the intended means. This work is now in its very early stages and has not yet been reported.

Eradication techniques excited much interest at the Fourth International Congresses on Tropical Medicine and Malaria in 1948, at which Soper[8] assessed their potentialities. It was clear that they are limited, there being no prospect of success against, for instance, a forest-haunting mosquito in Central Africa; but they have not yet been fully investigated, and the WHO Expert Committee on Malaria[9] has decided as a matter of research to foster an attempt at eradication of an indigenous anopheline from a mainland territory with no natural boundaries, creating artificial boundaries in their place. The relative values of eradication as a capital work and control by the newer methods as recurrent work have yet to be decided, but it can be said that the Cyprus scheme is a pioneer one in the development of eradication of indigenous species.

CONSULTANTS ADVISED TO SIGN

The Joint Committee on Monday of this week once more discussed with the officials of the Ministry of Health the question of arbitration. As a result of that meeting the Committee has decided to advise consultants and specialists to enter into permanent contracts. It was assured that no changes will be made in the terms and conditions of service without prior discussion in the medical section which is to be established as part of the Whitley machinery. The Ministry of Health agrees that remuneration is a subject on which there may be arbitration in the event of disagreement. The Whitley Councils, it should be clear, provide a mechanism for conciliation. If, for example, it is not possible to reach agreement on remuneration the matter can—save in exceptional circumstances—go to arbitration by common consent of the Minister of Health and of the medical profession. "Exceptional circumstances" means such events as a grave economic crisis. If only one of the parties is prepared to go to arbitration the matter can still be referred to a committee, to inquire into and report on the dispute, no doubt with recommendations.

It was made plain in the Committee Stage of the Amendment Bill that no party in the House of Commons will allow either side to compel arbitration. The Joint Committee may be congratulated on having secured from the Ministry agreement that remuneration is open to arbitration, and it is reasonable to assume that in the event of serious disagreement neither the Minister of Health nor the medical profession would in practice fail to seek the obvious and fair method of resolving a dispute—arbitration or a committee of inquiry. The Ministry of Health has agreed to delete from the opening paragraph of the contract the words "the Minister of Health." The Ministry, too, has agreed that patients admitted to private wards under Section 5 of the Act will pay professional fees in addition to maintenance charges, except where a public patient is admitted to a private bed for medical reasons.

In the light of the discussion in the Committee Stage of the Amendment Bill, which has been fully reported and commented on in this *Journal*, it is clear that substantial progress has been made. The question of arbitration affects other sections of the profession, notably general practitioners and those in the Public Health Service; no doubt they will now review their position.

POLIO-ENCEPHALITIS

There is at present an increase in the number of notifications of poliomyelitis. This is partly seasonal, but the figures indicate a greater rise than usual. With the increase in poliomyelitis, cases of encephalitis which must be attributed to the same virus are bound to occur. In the 1947 epidemic there was a higher proportion than usual of cerebral bulbar lesions with or without spinal involvement. When this happens during a poliomyelitis epidemic the diagnosis is easy, but at other times the aetiology can only be suspected. In 1947 Jennings[1] reported a small series of cases with encephalomeningitic symptoms which he believed were distinct from those of polio-encephalitis, and at the same time Laurent[2] described additional cases which he placed in the same unknown group. This view was criticized by McAlpine and his colleagues,[3] who concluded that in this country a brain-stem encephalitis, whether sporadic or occurring in small groups, is almost certainly due to the virus of poliomyelitis. Critchley[4] agreed with this opinion.

In this issue of the *Journal* case reports by Drs. G. H. Jennings, J. L. Hamilton-Paterson, and F. O. MacCallum, and by Drs. W. H. Kelleher, A. B. Bratton, and F. O. MacCallum, provide convincing proof of the identity of this type of encephalitis with poliomyelitis. This would probably have been decided some time ago if the necessary laboratory animals had been available: now that the wartime and immediate post-war scarcity is over and monkeys

[1] *Lancet*, 1947, 1, 471.

can be used for research purposes, the identity of the causal agent can be established. Future puzzling cases of encephalitis can be investigated in the same fashion. The pathological pictures in the two cases described are very much alike and correspond closely to the American descriptions. Though the spinal signs may be very slight, the most severe lesions occur in the cervical and lumbar enlargements of the cord. The brain stem is affected to a lesser extent, and the cortex and subcortex show only congestion or oedema. In spite of the paucity of pathological findings the clinical signs are obvious—apathy, twitchings, severe drowsiness, delirium, and cranial nerve palsies. Death may be due to acute bulbar failure. Jennings and his colleagues comment that the pathologist finds little to support the clinical picture of pyramidal involvement. It is probable, however, that what are relatively crude techniques may reveal little change if the signs are transient or if the patient dies at an early stage of the disease. Gross, though temporary, change in function can occur in other conditions, such as the acute post-concussion state or the post-epileptic state, with nothing or very little indeed to be found by the pathologist. An interesting clinical feature of the encephalitic cases is nystagmus—a relatively common finding—and that wild type of eye movement associated with difficulty of fixation known as opsoclonia. This suggests strongly that the median longitudinal bundle is affected in the brain stem. When recovery takes place from the encephalitic type of disease it is usually complete. This is to be expected from the mild pathological changes. The fact that death is due to bulbar failure, often of the respiratory centre, suggests that if these patients can be kept alive in a mechanical respirator till the acute phase is over their chances of survival are good. If, however, there is a failure of the vasomotor centre and the cardiac centre, then it is very unlikely that any therapeutic measure will succeed.

THE CHEMISTRY OF INSULIN

Interest in the chemical structure of insulin has been stimulated by the recent work of Dodds and his colleagues on the action of enzymes on the hormone[1 2 3] and that of Sanger[4 5] on its oxidation. The successful preparation of active and serviceable pancreatic extracts by Banting and Best in 1921 and the crystallization of the hormone by Abel and his colleagues in 1926 paved the way for the chemical investigation of the molecule. The protein nature of insulin was soon established, and studies were begun on the size of the molecule and the nature of the groups responsible for the specific hypoglycaemic effect. Behind much of this work was the hope that it might lead to a clearer knowledge of the mode of action of the hormone and—perhaps even more important—might make possible a laboratory synthesis of some relatively simple "modified" or "substitute" insulin. From all these chemical studies much of real value has been learned, but a satisfactory simple substitute or a synthetic insulin has not yet been found.

There is no evidence as yet of the presence in insulin of any amino-acid or grouping not normally present in other proteins. In dilute solution at *p*H 7–7.5 it has a molecular weight of about 48,000.[6] Treatment of the hormone with a variety of chemical reagents has shown that the disulphide linkages and the phenolic hydroxyl and the primary amino-groups in insulin are necessary for its pharmacological action. From these and other chemical studies it can be concluded that the hypoglycaemic action of insulin is due not to certain prosthetic groups or to some as yet unknown amino-acid in the hormone but to a special spatial arrangement of the ordinary amino-acids. This does not exclude the possibility that the characteristic effect on carbohydrate metabolism might be due to the activity of some fraction of the molecule—i.e., by a "submolecule"—of insulin. Sanger[7] has suggested that the submolecule of insulin has a molecular weight of about 12,000 and that it consists of four peptide chains bound together by —S–S— linkages; two of these chains have terminal glycine and two have terminal phenylalanine groups. Oxidation of the disulphide cross-linkages of insulin by performic acid gives the separate polypeptide chains, and a start has been made with the work of locating the various amino-acids in these polypeptides.[4 5]

Professor Dodds and his colleagues selected insulin as specially suitable for a general study of protein structure and the action of proteolytic enzymes on the protein molecule. When pepsin acts on insulin at *p*H 2 fragments are produced which have an average chain length of about seven amino-acid residues and a mean molecular weight of about 3,000.[1 3] Purified trypsin, unlike ordinary preparations of trypsin, has only a slight hydrolytic and inactivating effect.[2] Chymotrypsin, however, removes small peptides from the insulin molecule, leaving a more massive "core," which has a molecular weight of about 4,000 and apparently consists of the slightly shortened insulin chains united by —S–S— linkages. Further information about the nature of this insulin core will be awaited with interest.

The chemistry and mode of action of insulin are being investigated by many other methods. Vesicant-treated insulin, prepared by the use of compounds resembling mustard gas and containing radioactive sulphur, has been studied by du Vigneaud and his colleagues,[8] and Woolley[9 10] has described the separation of various peptides from enzymically hydrolysed insulin. The important observations of Dr. and Mrs. Cori and their colleagues have opened another field for research. They have shown that the *in vitro* inhibition of hexokinase (an enzyme which catalyses the formation of glucose-6-phosphate from glucose in muscle, etc.) by certain freshly prepared anterior pituitary extracts is neutralized by the addition of insulin to the system.[11] It is certainly too early to give a structural formula to the "key" part of the insulin molecule, but research during the past few years has undoubtedly brought nearer this desirable achievement.

HIGH FLYING AND DECOMPRESSION TREATMENT OF WHOOPING-COUGH

BY

H. STANLEY BANKS, M.D., F.R.C.P.

Physician-Superintendent, Park Hospital, Hither Green

In 1927 an air pilot of Strasbourg took his child suffering from whooping-cough for a flight to a height of 10,000 feet (3,050 metres). The child's cough was said to have ceased dramatically after three days. Before the war Dr. W. Matter (1946), of Strasbourg, did much pioneer work on aeroplane flights for whooping-cough, and the practice became popular in many countries of Europe and to some extent in South America. As a result of this and of some work done in Switzerland (P. Lauener and E. Maeder, 1942) during the war, several conclusions were reached: (1) that the best results were obtained in the fifth and sixth weeks of the disease; (2) that several flights were no better than one; (3) that an altitude greater than 10,000 feet was rarely necessary; (4) that the extreme cold at this altitude was harmful to some patients, and that for this reason the closed plane was better than the open one.

Claims for the Treatment

In 1939 a controlled experiment in Berlin on 88 children treated by aeroplane flights and 33 children treated under similar atmospheric pressures in the decompression chamber yielded slightly superior results for the latter, and in addition none were made worse by the decompression treatment. The highest claims made for the treatment about the year 1945 were: approximately 30% cured—that is, cessation of paroxysms within four days; 30% improved—that is, marked diminution of the paroxysms within seven to 10 days; and 40% no change or worse after seven days. At the same time it was generally agreed that the beneficial effect of the treatment depended upon low barometric pressure and low oxygen tension in the alveolar air rather than upon the actual purity of the air breathed. These results were statistically open to considerable criticism owing to the absence of controlled studies and the difficulties of assessment of cure and improvement in out-patients.

In 1946 Baldry and Richou published their first report on 300 cases treated in a decompression chamber in Paris. Selected cases of all ages from 2 months to 40 years were treated, and of those followed up for 21 days (44% of the total) there were 22% of cures in four days, 51% "improved," and 4% whose paroxysms were aggravated for some days after the treatment. Up to 1948 Richou had treated some 6,000 cases in Paris. His published conclusions include the following principles: (1) that the results obtained were independent of age and weight; (2) that the best time for the treatment is after the third week of the disease, preferably the fourth, fifth, or sixth; (3) that repetition of the treatment does not increase the percentage of successes—that is, a good result is obtained with the first treatment or not at all; (4) that contra-indications for the treatment are fever, respiratory and cardiac complications, epistaxis and any haemorrhage, nasopharyngeal infections, ear infections, hernia, surgical emphysema, and malnutrition. The rarefied air-pressure is regarded as the chief factor in a beneficial result. How it acts is unknown. It has been suggested that it may lead to a relaxation of bronchial muscle, damping down of the cough reflex, or alteration of the bronchial mucosa in some unknown way.

The method has its severe critics. In 1948 Bergquist treated 45 children in Stockholm—20 by aeroplane at 11,000 feet (3,350 metres) for 45 minutes, and 25 at similar low pressure in a chamber for 45 minutes. He stated that an analysis of the course of the disease, the frequency of paroxysms and vomiting, duration of the disease, bacillary findings, and changes in the blood picture showed no significant difference, and in his opinion flying and low-pressure chambers were completely without value in treatment of whooping-cough.

It is clear that a critical assessment of the treatment is required, preferably in in-patients, with radiological and haematological observations before and after. This is not easy to arrange, and to a large extent it will probably be

FIG. 2.—Inside the decompression chamber. Note the observation windows for use of doctor and technician, the telephone, the thermometer, and oxygen masks (for use in emergency only).

necessary to conduct observations on out-patients. One point that has not been established is the effect of the treatment on the various degrees of pulmonary collapse which so often complicate cases of whooping-cough in the later stages of the disease and which may not be obvious on ordinary physical examination. It is certain, however, that if there are any accompanying acute symptoms such as fever or cyanosis, or any signs of acute bronchitis, the treatment is contraindicated.

Conclusions

The conclusion at present from the work done is that the treatment is not a cure for whooping-cough in its early stages or for complicated whooping-cough. Its object is to clear up the persistent cough and vomiting of the later stages (e.g., the fourth to seventh weeks) in otherwise uncomplicated cases. Its success has still to be confirmed, and, in any case, seems to be limited. Trials are now proceeding at Park Hospital, where a renovated ex-R.A.F. decompression chamber has recently come into use. Of the 32 cases so far treated at the hospital, reports have been received on 22. In four cases the coughing had virtually ceased within four days and no vomiting occurred after the treatment; three cases were markedly improved, with very little cough and no vomiting seven days after treatment; and in 15 cases there was gradual improvement or no change. In one of the "cured" cases a symptomless right-middle-lobe collapse had completely re-expanded within seven days.

Public transport should not be used for cases of whooping-cough during the infectious stage, which is generally held to include only the first five weeks from onset of the disease, even although cough, whoop, and vomiting continue beyond that time. Applications for treatment should normally be made by doctors to the Emergency Bed Service, 10, Old Jewry, E.C.2 (Tel., Monarch 3000).

COMMONWEALTH AND EMPIRE TUBERCULOSIS CONFERENCE

PROBLEMS OF RESETTLEMENT

The main sessions of the second Commonwealth and Empire Health and Tuberculosis Conference were reported in the *Journal* of July 16 (p. 150). One of the closing sessions was devoted to psychological and social readaptation.

Dr. W. E. CHIESMAN (Medical Adviser to the Treasury) spoke of the difficulties which attended re-employment. In a group like the Civil Service such cases were numbered in hundreds. In 1948, with a working population of 300,000, there were between 500 and 600 primary and relapsed cases of tuberculosis. He had been surprised to find the difference of opinion which existed about the length of time for which a patient required treatment. Sometimes a man was discharged from hospital and told he could return to work almost immediately, while the man's own doctor recommended another six months' convalescence. The criteria of fitness to return to work needed clarification. Another point was that the returned patient might have a certain effect on his fellow workers. General propaganda had developed a fear of tuberculosis and an awareness of the disease, and it was natural that both employers and fellow-employees should desire reassurance. A satisfactory answer to these questions would clear up some of the main difficulties of rehabilitation. It was surely not unreasonable to employ persons whom the chest physician considered to be safe, but the follow-up ought to be improved by asking the patient to get an assurance from his doctor at regular intervals that he was not a potential danger to his associates. If there was a risk from tuberculous patients let it be assessed as accurately as possible, because the future policy for the re-employment of these people must depend upon striking a proper balance between what was good for the patient and what was safe for the community.

A number of industrialists and trade union leaders took part in the discussion on this subject. A description of work in a rheumatic unit was given by Dr. J. F. BACH (St. Stephen's Hospital, London), who said, incidentally, that he believed that happy and contented people did not develop rheumatoid arthritis. Chronic anxiety and shock immediately preceded the onset so often that he felt these must be trigger factors. In his clinic patients were selected for in-patient treatment according to the assessment of personality rather than according to the degree of joint deformity.

Dr. LEWIS MOORMAN (Oklahoma State Medical Association) discussed the psychology of the doctor–patient relationship in the readaptation to industry of sufferers from chronic disease. All good doctors who managed cases of tuberculosis became good psychologists and psychiatrists. A physician should always impress on his patient the importance of the partnership between patient and doctor in the difficult task of getting well.

Dr. TREVOR LLOYD DAVIES (Boots Pure Drug Company) said that the great difficulty about special centres for rehabilitation was that it was impossible to re-create the social relationship as it existed in normal industry. He realized that it was necessary to have these centres in order to get the patient back to industry, but at the very earliest opportunity the patient should return to normal industry. Something to the same effect was said by Miss OLWEN TAYLOR DAVIES, welfare liaison officer at Papworth Village Settlement. All the schemes developed under the Disabled Persons Employment Act, as well as voluntary schemes, she said, were satisfactory only in so far as they restored the individual to economic independence and a normal life. The segregation of unfit workers was not likely to lead to complete readaptation. Experience at Papworth had shown that the patients most easily lost their sense of inferiority when working with fit people.

Infected Milk

At the final session of the Conference Dr. EDITH SUMMERSKILL, M.P., Parliamentary Secretary to the Ministry of Food, said no Government could ignore the danger to the health of the community arising from infected milk. The ultimate objective was to secure that all milk sold for domestic consumption should be in closed containers, fitted with overlapping caps to prevent the contamination of the mouth of the bottle, and that the milk should be tuberculin-tested, pasteurized, or sterilized. Unfortunately, this new policy could not be applied immediately to the country as a whole because of insufficiency of pasteurizing and bottling plants. The makers of these plants were so inundated with orders that it would take a long time to complete them. It was therefore proposed to apply the restrictions first to groups of large urban areas, and then to extend them so far as practicable to rural areas. It was probable that some twelve months would elapse before any area would be specified for this purpose, but it was hoped to complete the specifying of all urban areas within five years and most, if not all, of the rural areas within ten years.

Mr. J. N. RITCHIE (Ministry of Agriculture and Fisheries) said that at the end of May last there were 39,997 attested herds, but progress was not equal throughout the country, and the greatest progress was not necessarily attained where the incidence was originally low. The number of cattle in tubercle-free herds (attested and T.T.) in Great Britain was approximately 1,780,000. The sale of tubercle-free milk to Milk Marketing Boards for the year ended March 31, 1948, was 354 million gallons, compared with 141.6 million gallons for the year ended March 31, 1943.

According to a report in the *News Chronicle* (July 1), the health committee of the Marylebone Metropolitan Borough Council has decided to press for revision of the exemption of Government departments and Crown properties from inspection by officers of a local authority. The medical officer of health is said to have been denied access to inspect staff canteens in Government departments.

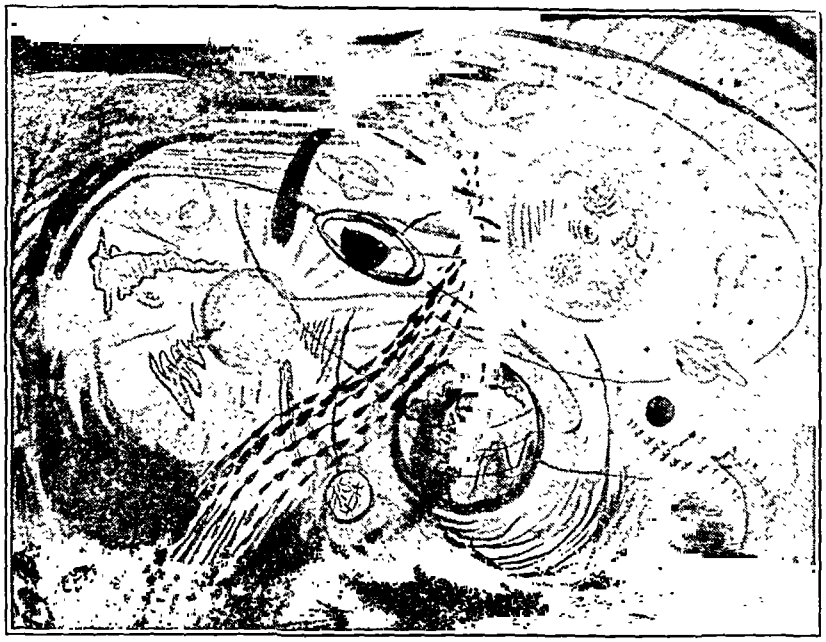

FIG. 1.—A schizophrenic patient's drawing of two universes—the real intermingling with the unreal. A typical expression of thought disturbance.

PSYCHIATRY AND ART

NETHERNE HOSPITAL EXHIBITION

For the last three years a number of patients at Netherne Psychiatric Hospital have been encouraged to paint pictures in the course of their treatment, and an exhibition of some of their productions was held at 1, Grosvenor Crescent, London, S.W.1, on July 11–16. Though nearly all the work was by people untrained in any of the arts, much of it was remarkable for the high quality of its aesthetic expression. Many of the paintings revealed vigour, imagination, and depth of feeling, and some of them were reminiscent of the products of surrealism.

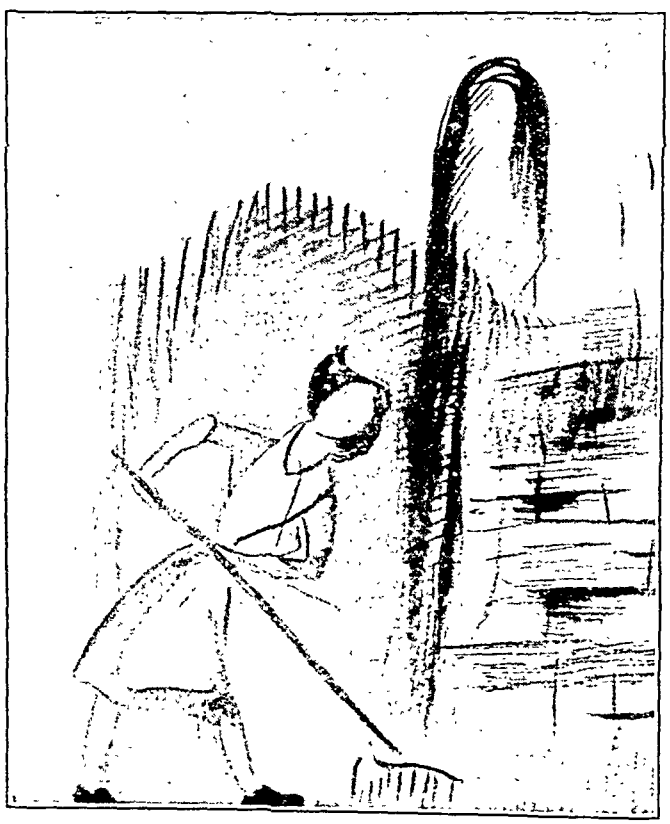
A professional artist, Mr. E. J. Adamson, is attached to the hospital to help the patients overcome the difficulties of expressing themselves in an unfamiliar technique, but he leaves the choice of subjects and the actual painting entirely to the patients themselves. They paint how and what they like, but if one of them wants to know, for example, how to draw a man sitting down Mr. Adamson shows them on a separate piece of paper.

Discussing the pictures on July 14, Dr. E. Cunningham Dax, medical superintendent of the hospital, said he did not think they should use the term "art therapy." There were nearly as many "therapies" in psychiatric nomenclature as there were "phobias," and it brought only disrepute on their experimental methods of attacking psychiatric illness if they were labelled as curative without statistical evidence to support their claims. A better adjustment appeared to be made, however, when facilities were given for artistic expression rather than for some form of occupational diversion.

Painting might provide emotional release. He had seen many patients reflect their state of mind in their drawings, and apparently they felt all the better for it. The translation of emotions into paintings might give valuable information to the psychiatrist, and evidence of a patient's progress might be obtained from his paintings without ever having to discuss them. Painting might cut down the time required for psychotherapy, since some patients expressed themselves more easily on paper than in speech, and came more quickly to the interpretation in that way. Useful data might be accumulated in time on which to base the study of mental functions.

In reply to a question, he said that patients often did their most interesting work when their minds were disturbed.

FIG. 2.—Entitled "Housework," this is one of several hundred pictures drawn by a psychopathic girl who was stabilized through her work in the studio group. Since discharge she has worked for two years as a Land Girl, though previously she had never held a job for more than three weeks.



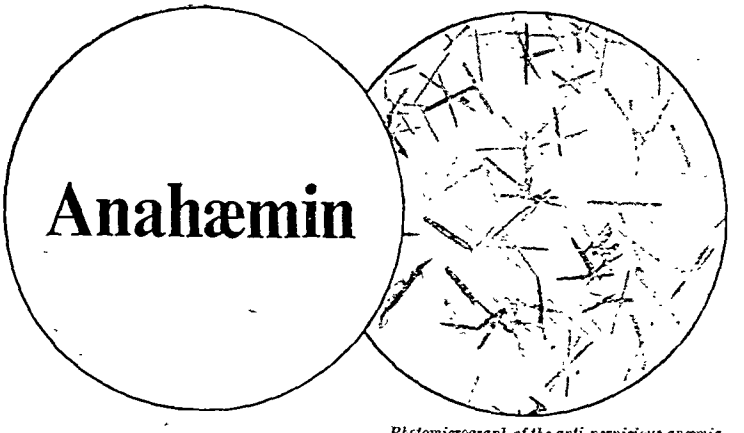


FIG. 3.—Entitled "The Lizard," this was painted by a woman with an anxiety state and some paranoid features. The patient was feeling like the lizard, which appears in the centre.

Vitamin B_{12} in

Anahæmin

Photomicrograph of the anti-pernicious anæmia (A.P.A.) factor, vitamin B_{12}, isolated from Anahæmin

Since its introduction 12 years ago Anahæmin has been noted for its high potency and clinical reliability. It is for these reasons that Anahæmin is in universal use for the treatment of the macrocytic anæmias.

Although the potency of each batch of Anahæmin has always been established clinically before issue, further confirmation of its hæmopoietic activity is now afforded by the *isolation* of the anti-pernicious anæmia factor vitamin B_{12}, in crystalline form, *from routine batches of Anahæmin**.

When PAIN *is* INSUPPORTABLE.....

The test of experience has established 'Physeptone' as the outstanding analgesic. Causing neither hypnosis nor constipation, it may with advantage replace morphine in the treatment of pain in patients confined to bed. So potent a drug is seldom required in ambulant subjects and it should therefore be withheld from them except in rare cases. 'Physeptone' is issued as compressed products of 5 mgm. in bottles of 25 and 100, for oral administration, and as ampoules of 10 mgm. in 1 c.c., in boxes of 12, for parenteral administration. Literature on request.

Why 'Ribena' in fatigue and asthenic states?

Because controlled clinical tests carried out in many large factories and institutions have indicated that *natural* vitamin C, in the form of Ribena blackcurrant syrup, definitely tends to prevent fatigue, and thus increase the capacity for strenuous physical effort. It has been observed also that the occurrence of muscular cramp following prolonged severe exercise has been lessened, and mental alertness increased.

'Ribena' is employed, too, in asthenic states as a general restorative and for the biological effect of its vitamin C content or utilisation of iron by the organism.

'Ribena' is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it will not upset the most delicate stomach. It is particularly rich in natural vitamin C (not less than 20 mgm. per fl. oz.) and associated factors.

THE ROCKEFELLER FOUNDATION

POPULATION PROBLEMS

The Rockefeller Foundation last year appropriated nearly 15 million dollars for public health projects, medical research, and studies in the natural and social sciences. The new president of the Foundation, Mr. Chester I. Barnard, who succeeded Mr. Raymond Fosdick, suggests in his latest annual review[1] that in future wider fields of study may be contemplated, including some of those hitherto regarded as the preserve of religion and philosophy. There is need, he says, for a reclassification of the problems of modern society, and especially those population problems which often underlie national, class, and racial conflicts. They lend themselves to generalization and oversimplification, with quack remedies as a natural consequence. The problems are complicated by wide differences in customs, rules of inheritance, moral ideas, and religious principles. It is customary to say that the world is over-populated: "About half the world's population," says this review, "is close to starvation, and another quarter suffers from malnutrition." But the world may not be over-populated if its peoples will co-operate in the economic use of natural resources and if productive capacity can be increased. The obstacles to what Mr. Barnard calls social engineering are human inertia and insufficiency of knowledge.

Research work in genetics, endocrinology, the physiology of reproduction, and sexual behaviour has already been supported by the Foundation. The studies of Kinsey and others have emphasized the biological maladjustment between the sexual drive and population needs. The bearing of this on morals, on the incidence of venereal diseases, on frustration, and on crime is evident. In the field of human behaviour the rapid changes introduced by modern technology raise many questions. Do these changes challenge the meaning and relevancy of ancient moral precepts? What is the bearing of endocrinology or pathology on the moral assessment of human conduct? What is the relevancy of the application of ancient codes of individual behaviour to modern corporate action? The Rockefeller Foundation is proposing an examination of the nature of the conflicts of ethical systems to-day in the light of modern changes. No doubt it will find that these subjects of inquiry are much more controversial than investigations concerned only with public health and medical science. But the Foundation is taking this course because it believes that there can be no satisfactory solution to the problems of our civilization which does not take into account the ideals and spiritual aspirations of men.

WESTMINSTER MEDICAL SCHOOL

CENTENARY CELEBRATIONS

Westminster Medical School celebrated its centenary with a meeting of the staff and students held in Church House on July 13. The Earl of Athlone, Chancellor of the University of London, gave the opening address. The Dean of Westminster, Dr. Logan, Principal of London University, Lord Nathan, chairman of Westminster Hospital, and Dr. E. R. Boland, Dean of the Faculty of Medicine, London University, were among the guests. Also present were two former deans of the Medical School—Sir Ernest Rock Carling, who held office from 1909 to 1912, and Sir Adolphe Abrahams, who was dean from 1934 to 1943. Mr. H. M. Clowes, chairman of the Medical School Committee and Council, was in the chair.

Lord Athlone said that the formal connexion between Westminster Hospital and the Medical School dated only from 1849, but a medical school had existed as an offshoot of the hospital as early as 1834. He was glad to say that ties between the school and the hospital remained as close as ever, although the Medical School was part of the University of London and enjoyed a separate legal existence, with its own council and academic board. He disclosed that plans were already being considered for erecting new buildings and founding a preclinical school, although the present buildings were opened in Horseferry Road only 11 years ago. The support of the University was assured for this scheme of development.

There were at present 230 students, and the main difficulty was not to attract more undergraduates, as had been necessary in the days after the 1914–18 war, but to devise means of discriminating among hundreds of eligible and desirable applicants.

Sir Ernest Rock Carling spoke of the early history of the Medical School. He said that preclinical subjects were formerly taught, but were given up because the number of students was so small. He recalled that the Westminster Hospital was the first to build aseptic operating theatres in London, the first to make use of radium in treatment, and one of the first to employ an almoner. Sir Adolphe Abrahams discussed the advantages of the small school, where a greater number of men from other hospitals could be included in the staff.

Mr. G. H. Macnab, the present Dean, spoke of the future of the Westminster Hospital and Medical School, the difficulties in selecting students, and the pains taken by the authorities to choose the right men and women.

THE OSLER CLUB

The annual dinner of the Osler Club, held at the Royal College of Surgeons of England on July 12, celebrated this year both the centenary of the birth of Sir William Osler and its own coming-of-age. To mark the occasion several distinguished guests were invited, including their Excellencies the Chinese and Italian Ambassadors and the Austrian Minister, Dr. R. Gottlieb (representing the High Commissioner for Canada), Dr. A. S. Osborne, of the U.S. Public Health Service (representing the American Ambassador), Mr. Gilbert Frankau, Dr. Wu Lien Teh, the distinguished Chinese medical historian and organizer of the Plague Prevention Service in Manchuria, Dr. Lewis J. Moorman, editor of the *Journal of the Oklahoma State Medical Association*, and Mr. Geoffrey Cumberlege, of the Oxford University Press, which has made possible the publication of a volume of selected writings of Osler, to appear in 1950.

The chair was taken by Dr. A. White Franklin (an original member of the Osler Club), who outlined its future objects. During the dinner, speakers were introduced by Dr. W. R. Bett (another original member). The Chinese Ambassador spoke of Osler as an international physician, and the Italian Ambassador recalled Osler's visits to Italy both as medical man and as bibliophile. The Austrian Minister reminded his listeners that Osler had rounded off his medical education with a visit to Vienna.

After dinner the Oslerian Oration was delivered by Mr. Gilbert Frankau, who, although professing his ignorance of medicine, made an amusing and provocative comparison between the state of medical knowledge and public health in 1849 and the present day. He believed that the renaissance of medicine which had coincided with Osler's early years as a physician had contributed materially to his greatness, for he had taken advantage of the great opportunities open to him.

Dr. Moorman spoke of the reverence with which Osler was still regarded by American physicians, who, he claimed, knew him better than anyone else, for he had been with them longer than with the British. In Oklahoma, Dr. Moorman's home city, an Osler Society flourished, and an Osler building provided offices for a number of medical men. Dr. Moorman concluded by presenting several documents to add to the collection of Osleriana possessed by the Osler Club.

EPSOM COLLEGE

The Royal Medical Foundation of Epsom College announces that the following pensions, scholarships, and grants are now available:

A "Hadlow" Pension of £70 per annum for a medical practitioner or the widow of a medical man fully 60 years of age.

One or two St. Anne's Scholarships for girls attending Church of England schools. Candidates must be fully 9 years of

age and the orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected.

Pensions for necessitous medical men fully 55 years of age, provided they have been registered for five years; for the widows of medical practitioners fully 60 years of age; and for the spinster daughters of medical practitioners of 55 years and upwards. (Awards are made as vacancies occur.)

Scholarships and grants for children of either sex, not necessarily orphans. Candidates must be of public-school age and in need of such help.

Grants from the Eastes Trust for the relief of registered members of the profession of any age, their widows and orphans, and for the educational assistance of their daughters or sons.

Full information and forms of application are available, on request, from the secretary, Epsom College, Surrey.

Preparations and Appliances

AN "OVERGLOVE" FOR INTRAUTERINE AND OTHER MANIPULATIONS

Dr. J. A. MOYSE, of Mitcham, writes: Access to the uterine cavity, even under the most favourable conditions, is always fraught with the risk of infection. For the practitioner who has to carry out an intrauterine manipulation I have designed what I call the "overglove," a rubber covering for the sterile glove used in cases of adherent placenta requiring manual removal.

The overglove is a retractable covering for the sterile "operating" gloved hand, designed to be carried over it into the potentially septic field of the lower genital tract. At the desired level the overglove is held back by the non-operating hand pulling on the cuff, so that the encased sterile glove can emerge from a suitably shaped slit. The edges of this slit are continued into flaps which are invaginated into the lumen of the overglove and there held between the sides of an appropriate pair of fingers. These flaps are everted as the slit retracts over the emerging sterile gloved hand, which is thus uncovered only in the field of its application. Not having come into contact with anything other than the inner surface of the overglove, the gloved hand must be at that moment in its original degree of asepsis.

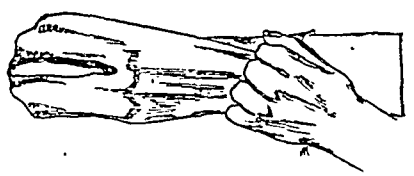

FIG. 1

This sequence of movements or manœuvres is shown in the accompanying sketches. Fig. 1 depicts the overglove more or less "in plan" but with the operating hand within it. The non-operating hand, grasping the cuff, is exerting sufficient pull to cause the overglove to retract. The slit is beginning to widen as its flapped edges are everted. Fig. 2 shows the sterile

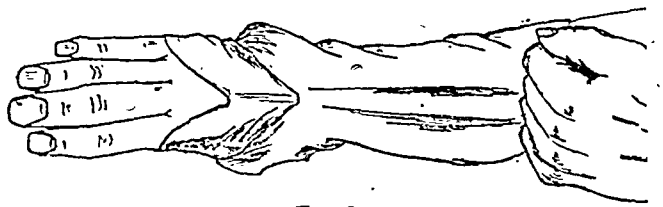

FIG. 2

gloved hand emerging from the stretched slit, the flaps of which closely invest it. Continued traction is maintained and the movement completed with the slit retracted to the wrist and the gloved hand fully outside the overglove.

The overglove is manufactured by Messrs. J. G. Franklin and Sons, Ltd., Colvestone Crescent, Dalston, London, E.8.

Correspondence

Ovarian Hilus Cells

SIR,—While the *Journal* of July 16 (containing our pap entitled "Association of Certain Ovarian Cells with End metrial Cancer") was being printed, our attention was draw to a paper by W. H. Sternberg in the *American Journal Pathology* for May, 1949 (25, 493), on the human ovarian hil cells. The author points out that there is little reference to t cells in the American literature, and we believe that Sternber paper is the first full description of the cells written in Englis He groups the cells, known to us as paraganglion cells, amor the hilus cells, although we feel that the cells we descri belong to a different type. Nevertheless, there is an accura description of the relation of some of the cells to the bloc sinuses and lymphatic spaces. We must emphasize, howeve the activity of these cells in cases of carcinoma of the end metrium, particularly in early cases.—We are, etc.,

Tuberculosis in Industry

SIR,—Having been one of those responsible for the repor of the Medical Research Committee of 1915 dealing wi the incidence of tuberculosis in the boot and shoe indust I am interested in the letters you have published from D Stephen Hall (June 11, p. 1049) and from Dr. S. Roodhou Gloyne (July 2, p. 31). Both writers, and, indeed, Drs. Ali Stewart and J. P. W. Hughes (May 28, p. 926), seem to ha overlooked that the subject received extended statistical stu in the Harben Lectures for 1924.[2]

Briefly, the mortality data there quoted indicate that (*a*) occ pations with no health risk experience low mortalities fro every cause of death; (*b*) occupations "infected" with tube culosis (e.g., the boot and shoe industry, tailoring, and printin experience a high mortality from tuberculosis, but lo mortalities from every other cause of death; (*c*) occupatio exposed to the silica dust hazard experience a high mortali from tuberculosis and from other diseases of the damag respiratory organs, such as bronchitis and pneumonia, b low mortalities from other causes; and (*d*) occupatio exposed to a general depressing agent, such as alcohol (e. barman), experience high mortalities from every cause of deat —I am, etc.,

E. L. COLLIS.

SIR,—I must thank Dr. S. Roodhouse Gloyne for h courteous reply (July 2, p. 31). On rereading my letter (June 1 p. 1049) I can detect some evidence of ill-humour, for whi I am sorry. This display of emotion arose because I fanci I saw in the "mistakes" of Drs. Alice Stewart and J. P. W Hughes symptoms of a habit common among those who ho the bacteriological concept of tuberculosis. They use langua which presupposes the truth of their concept, falsely equati "infection" with "disease," and they tend to regard a reproof of this habit as the objection of a pedant. Neverth less, the offence is rank and fundamental, and its repetitio acts as an irritant to those of us who think less highly of t part played by germs in the aetiology of "disease."—I am, et

STEPHEN HALL.

London, W.1.

Incontinentia Pigmenti

SIR,—I read with interest the article by Dr. W. L. Caln entitled "Congenital Hemiatrophy Associated with Other Co genital Defects" (July 9, p. 56). The history of that ca revealed that the child was born with a vesicular eruption the left leg and dorsum of both hands. There was also line

pigmentation over the anterior part of the trunk on the left side and over the lateral wall of the thorax. The vesicular eruption left scarring after healing. Furthermore, teeth anomalies developed, and in addition to these defects a congenital hemiatrophy was demonstrable.

The history of a vesicular eruption at birth with peculiar linear pigmentations, combined with other congenital defects, is characteristic of the condition known as incontinentia pigmenti (Bloch–Sulzberger[1]). I had the opportunity of diagnosing three such cases at the Hospital for Sick Children (Skin Dept.—Dr. R. T. Brain). These are going to be published soon. One of the cases was shown at the Dermatological Section of the Royal Society of Medicine by myself,[2] and I feel that Dr. Calnan's case belongs to the aforementioned syndrome and that the hemiatrophy is a new feature which was not described in the previous cases.

Less than twenty cases have so far been described since 1926, but I believe that many cases of incontinentia pigmenti pass undiagnosed.—I am, etc.,

London, W.C.2. H. HABER.

Dysentery in South Persia

SIR,—I have read the article by Dr. Ian S. Stewart (April 16, p. 663) on this subject, and, while the classifications of the different types of bacillary dysentery may be of value, the article generally is not above criticism and I would beg space to make some comments and criticism on it.

In the first place it is hardly accurate to assume that the conditions as found in Abadan may apply to the rest of the province of Khuzistan or those other parts which go to make up the rest of South Persia. There is quite a difference between the conditions of life in, say, Ram Hormuz, a rural native town in the desert plain, and the conditions as found in the industrial area of Abadan lying on the Shatt-al-Arab delta. Secondly, the time interval of the experiment is far too short to justify the conclusions reached that a method of control has been found. Dysentery, like so many other infective diseases, is a seasonal condition and also varies in its intensity from year to year. It would be of interest to know the disease incidence in the previous and succeeding years.

Thirdly, the easy dismissal of amoebiasis, based on the laboratory findings alone, as a condition of importance is not one that many clinicians would make. This condition is notorious for its quiet, unobtrusive, yet sinister presence. Many cases of amoebiasis can only be diagnosed clinically and in their response to anti-amoebic treatment; many cases too seldom have dysenteric symptoms, and *Entamoeba histolytica* may never be found—especially is this so in the chronic form. It is noted also that the use of the sigmoidoscope as an aid to the ascertainment of cure is not mentioned.

My chief complaint is, however, on the assumption by the author that a means of control of bacillary dysentery has been described. This is far from being the case, and, if it is believed that the described method of treating those workers reporting sick with bacillary dysentery "will bring about a steady reduction in the incidence of the dysenteries," it is to be hoped that it is believed by a very small minority.

It is true that this single approach to the eradication of a disease has been the dream of others, as for example the dream that quinine would eradicate malaria, that "606" would eradicate syphilis, or that tryparsamide would eradicate sleeping sickness, but to imagine that the described method will control such an unhygienic condition as dysentery and in such an area as the Persian Gulf, where the sanitation and personal hygiene of the bulk of the people are of a very low standard, is surely wishful thinking at its maximum.

It may come as a surprise to Dr. Stewart and to others to learn that of the 30,000 workers mentioned in the experiment only 15% approximately are housed in anything like reasonable conditions, with modern sanitation, and of this 15% many have still to learn how to use the fittings supplied; most of the remaining 85% live in the congested townships of Abadan town and Ahmadabad, where it is not unusual to find up to six families of three or four persons each living in a single room. Some, indeed, have no living abode at all and sleep on the ground around the covered market-places or in doorways, or share a stable or garage with some animal or car.

While it is true that public lavatories are provided, any vacant space serves as a place where nature's calls may be answered—the local inhabitants not being at all fastidious—and the whole district is mostly polluted by faeces, and flies are legion. I would in all humbleness suggest that if control measures are being applied to control bacillary dysentery those measures suggested in an excellent chapter in that admirable book, *The Control of Common Fevers* (London, 1942), be used: or, where these more modern measures cannot be applied completely, at least the instructions laid down thousands of years ago and described in the book of *Deuteronomy* (xxiii. 13) be carried out. Chemotherapy may have a place in reducing the carrier rate, but nothing can replace the fundamentals of sanitation and personal hygiene in the control of dysentery.—I am, etc.,

Abadan, S. Persia. LAWRENCE G. BRUCE.

Pylorospasm and Uraemia

SIR,—In a study of the toxaemia of acute intestinal obstruction (1923) I used the subtitle "Vomiting as a Pathological Force": the case of pylorospasm reported in the *Journal* (July 2, p. 18) shows how justified was, and is, that opinion. The malaise of sea-sickness, due to an aberration of the blood-flow through the liver occurring before the vomiting begins, is made much worse with the repeated vomiting; and deaths have ensued from sea-sickness alone. The deaths following cholecystectomy, in which the kidneys may become gravely implicated, are to be ascribed to the post-operative vomiting, and only to that. The bad results following caesarean section for eclampsia formerly experienced were due mainly, or indeed solely, to the post-operative effect of the general anaesthesia. With modern methods of rendering the operative area insensitive, by which post-operative vomiting is eliminated (and of which in these cases spinal analgesia is the best), the picture is completely changed; so that we know that in eclampsia the most satisfactory procedure is to empty the uterus, to relieve the vascular disturbance induced by the progressive distension of the abdomen and magnified enormously by the convulsions (in which the abdominal musculature does not become flaccid—the abdomen is as hard as a board) as soon as possible. The day of hypothetical toxins causing pathological changes in all these cases is past.

The case of pylorospasm in an adult related by Dr. E. N. Russell supports this statement. Dr Russell expresses the opinion that in his case the cure of the gastric trouble resulted from the realization by the patient—a professional man, at the time about 30—that it was due to psychological causes: causes which, I presume, cannot be supposed to have acted by way of producing or of inducing the appearance of a toxin. In treatment, "antal" was peculiarly effective. Antal, we are told, consists of a mixture of atropine and of sodium bromide. Antal cannot be expected to operate by neutralizing a toxin. There was, then, no toxin: yet uraemia occurred. The output of urine varied from 14 to 70 ounces (400 ml.–2 litres) a day: and the blood urea showed considerable excursions—from 200 to 72 mg. per 100 ml. within five days. And the patient, now aged 60, is presumably alive and well. A preceding renal disturbance can be eliminated.

When one considers the structure of the kidney and the long and circuitous course of the tubules through which the urine percolates, it is not difficult to understand that with great contraction of the abdominal wall muscles, such as occurs with vomiting, there is obstruction to the flow of urine and, indeed, to the blood stream within the kidney. The same occurs with strenuous rowing. After a race, the urine of all eight men, each an athlete in perfect health, contained albumin; some of the urines contained blood, and some (I believe) casts (Collier). I have pointed out already that occlusion of the ureter with diuresis in play causes the kidney to become almost bloodless (Brodie); and that a continuous compression of the

kidney itself, such as occurs in concealed accidental haemorrhage, must produce the same result by occluding the Henle hair-pin corners and thrusting bodily the pyramids of the kidney into the renal pelvis, like a cork into a bottle (*British Medical Journal*, 1949, **1**, 584). In the case of repeated vomiting we have a series of compressions : these must present an explanation much more acceptable than the play of any toxin to the student of medicine conversant with the nature and effect of physical force.—I am, etc.,

Rugby. R. H. PARAMORE.

Necropsies and Tuberculous Infection

SIR,—With reference to your annotation (May 21, p. 907) on the above subject, it may be of interest to recall that Hermansson[1] reported as follows in 1939 :

"After examining the carcasses of tuberculous cattle, the meat inspectors washed their hands in sterile water. This was centrifuged, and the sediment injected into guinea-pigs. Eleven of the 15 inoculations produced tuberculosis in the guinea-pigs. . . . The rinse water from the towels used by the meat inspectors was injected into guinea-pigs, producing tuberculosis in every instance."

—I am, etc.,

London, W.C.1. G. P. WEST.

Large Dose of Curare

SIR,—It is a well-acknowledged fact that patients vary markedly in their susceptibility to different anaesthetics (as indeed to drugs in general). I feel that the case reported below is worth recording, because of the abnormally large amount of curare required by the patient in a relatively short time.

The patient, a young man of 22 in the Merchant Navy, weighing 150 lb. (68 kg.), was to have a partial gastrectomy. There was a history of perforated gastric ulcer at the age of 16 years, with a further operation three weeks later for liver abscess. Unfortunately I have not been able to ascertain the amount of anaesthesia required on these occasions, though obviously curare would not have been used in those days. He was a teetotaller and smoked about ten cigarettes a day.

The anaesthetic technique used has been described elsewhere.[1] Sodium thiopentone (0.75 g.) and *d*-tubocurarine chloride (25 mg.) were required before visual intubation and packing of the throat could be satisfactorily accomplished. Notwithstanding this already significant dose of *d*-tubocurarine chloride, a further 10 mg. had to be given before the abdomen could be explored in comfort. Further maintenance doses were given throughout the operation, the respiration remaining regular and quite deep throughout. Shortly before closure a further dose of 5 mg. *d*-tubocurarine chloride had to be administered, in order to supplement the relaxation for closure of the peritoneum.

The duration of the operation was 90 minutes, during which time a total of 70 mg. of *d*-tubocurarine chloride and 2.5 g. of sodium thiopentone were given. At the termination of the operation "prostigmin" (5 mg.) and atropine (gr. 1/60=1 mg.) were administered, and the patient returned to the ward with good respiratory exchange and in satisfactory general condition. Convalescence was uneventful. All the injections were given through a Gordh needle, which was unquestionably in the vein.

The dose of *d*-tubocurarine chloride in this case was so much greater than any I have experienced or read of that I feel it will be of interest to all anaesthetists.—I am, etc.,

Manchester. M. SWERDLOW.

Treatment of Retained Placenta

SIR,—In these days of synthetic medicine, diplomas, etc., it is refreshing to read some of the facts of life as expressed by those capable of using their powers of observation and confirming them by experience. Mr. W. G. Mills (June 18, p. 1098) puts in a nutshell the true position regarding retained placenta, and Sheehan, from a pathological standpoint, has confirmed that death occurring from this cause is due to shock. Every obstetrician of experience must have repeatedly observed the rapid onset of (often extremely severe) symptoms of shock in patients retaining the placenta with, or equally frequently without, any degree of haemorrhage, even in normal deliveries.

If ever the saying, "He who hesitates is lost," had apt application, retained placenta is the situation bar none. While textbooks still reiterate the two hours' wait after delivery, which must have originated in a generation of mothers very different in their resistance to shock from the present, one can only say from experience how often lives have been saved by making sure the placenta is removed definitely before two hours, and, all things being equal, the longer before the better. In my own domiciliary and hospital practice every midwife long since knows the rule—no placenta inside after one hour.

As to substances necessary for resuscitation (Dr. C. T. H. Whiteside (June 4, p. 1005) and others), in the exceptional cases when this is necessary, if haemorrhage is the cause blood holds the field, but many a life can be saved by either saline or plasma till this can be obtained, or with ancillary restorants.

I cannot agree with Mr. Mills that "the first time the hand is plunged into the uterus in search of the placenta is an awful experience," as that is the very thing which must not occur. Passing of the hand with the utmost gentleness, even over the already stretched perineum and thence through the cervix, is of the highest importance, and failure to recognize this all-important fact is in itself sufficient to precipitate already oncoming shock, even to a fatal issue. While bearing this in mind, it is possible manually to remove a placenta even without anaesthetic in a bad-risk subject, and the writer has more than once been under the necessity of so doing.

While Mr. Mills rightly stresses sterile gown and gloves, he will be fortunate if one night he will not have to be satisfied with thorough scrubbing-up, and hands and arms soaked in antiseptic up to the elbows. In the war years Dodd and others confirmed this as being satisfactory, and more than once I have had to prove its truth, and I have yet to see my first patient to be infected in this way.

I join with him in marvelling at the reluctance of the average practitioner to undertake this simple and relatively easy course out of an often otherwise desperate dilemma, where real terror can only be replaced by sheer joy for all concerned.—I am, etc.,

Altrincham, Cheshire. H. A. LOGAN.

Transfusion in Domiciliary Midwifery

SIR,—As one associated with the obstetrical "flying squads" in the Windsor area I should like to make the following points for consideration. Most emergency calls are made by practitioners because of collapse of their patients of such degree as to make it unwise for them to be transferred to hospital before preliminary resuscitation. The majority of these patients have been delivered of their infants, for cases of ante-partum haemorrhage can usually be sent to hospital by ambulance while their general condition is still satisfactory.

The causes of collapse after childbirth can usually be grouped under the headings : (1) traumatic (? obstetric) shock, without bleeding, and (2) shock following bleeding, with or without associated trauma. With regard to the former—often cases with retained placenta—one might suggest that attempts at manual expression should not be made unless the doctor is prepared to follow this manœuvre with manual removal if necessary. If not, it is better for the patient to be transferred to hospital with the placenta *in utero*, for repeated attempts at manual expression cause profound shock, especially when performed without anaesthetic. Cases of collapse in this group often respond satisfactorily to plasma alone.

If bleeding occurs during the third stage the above principles apply, but uterine massage and intravenous ergometrine can be used in emergency. It is true that the latter may make subsequent removal of the placenta a matter of greater difficulty, but this consideration should not prevent the use of a possibly life-saving measure.

Furthermore, may I make a plea for more frequent blood grouping and rhesus factor estimation during the antenatal period ? In this area these tests are done as a routine in all hospital and council antenatal clinics, and if the patient is given a copy of the report for her retention it may be invaluable in the event of an urgent blood transfusion being necessary at a later date. It is not possible for the "flying squad" to do

An anti-histamine of wide application

HISTOSTAB is one of the most satisfactory antidotes for histamine now available.

In the treatment of a wide range of allergic conditions Histostab has few undesirable side-effects. It may be given orally, or by injection when rapid action is required. It will control allergic urticaria and eczema, and will relieve the itching in certain cases of pruritis. It has proved of value in cases of sensitivity to Insulin, Liver and Penicillin, suppressing the unpleasant effects and allowing treatment to be continued.

As Compound Solution of Histostab it is available for nasal and ocular instillation in vaso-motor rhinitis and hay fever.

Histostab Tablets. Bottles of 25 x 0.1 G. tablets.
Injection of Histostab. Boxes of 6 ampoules of 2 ml. (0.1 G.).
Solution of Histostab Compound. Bottles of ½ fl. oz.

HISTOSTAB

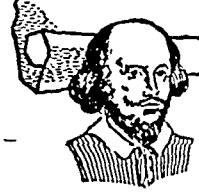
KAYLENE BRAND

The Liniment with a constitutional action

ANALJOL

A methyl aspirin preparation for external use in rheumatism and neuritis. It is non-staining and non-greasy and has an agreeable odour.



A double action, analgesic and counter-stimulant, supported by the effects of aspirin esters operating locally and constitutionally, ensures substantial relief from pain arising from the common fibrositic disorders of muscles, ligaments, nerves and joints.

Formula :—
Methyl Aspirin 12% Phenyl Aspirin 2%
Camphor 12% Menthol 8.75%
Ol. Thymi Rub. 8%
Alcoholic Solution of Terpineol 57.25%

PYRAMID WORKS - WEST DRAYTON - MIDDLESEX

more than a simple cross-match in an emergency, and owing to the shortage of rhesus-negative blood, at any rate in this area, the choice may lie between a plasma infusion or the use of rhesus-positive blood, and we have seen some serious complications through the use of the latter. When the rhesus factor is unknown and rhesus-negative blood is not quickly available I would advocate the use of plasma as a temporary measure pending full blood investigation, especially in a multigravida or patient who has had previous blood transfusion.—I am, etc.,

Windsor. F. H. FINLAISON.

Weight-reducing Diet

SIR,—Dr. H. L. Marriott's note (July 2, p. 18) on a causal relationship between the consumption of boiled potatoes and slimming will probably arouse lay interest. Some candidates for slimming, however, might conceivably prefer to follow the advice given to the late Mr. William Banting by the late Mr. Harvey, F.R.C.S., in 1864, and substitute wine and spirits for the drabness of milk and potatoes. The diets published by Mr. Banting and by Dr. Marriott are not greatly dissimilar in other respects.

The respective calorific values of Mr. Banting's daily alcoholic intake and Dr. Marriott's allowance of milk and potatoes are approximately the same, but, whereas a boiled potato is consistently and monotonously just a boiled potato in looks, odour, and taste, there is a wide and interesting selection of wines and spirits with their different vintages, colours, bouquets, palatabilities, and gusts satisfying to the veriest tyro who desires to lose weight pleasantly.

At the ripe age of 66 Mr. Banting lost 46 pounds (20.7 kg.) on his alcohol-positive, milk-and-potato negative diet, and enjoyed doing so. So much interest did Mr. Banting's simple weight-reducing diet (published and distributed free of charge) cause, that some eighty years ago *Punch* broke into verse with a poem that ended thus:

> "To avoid, if you wouldn't grow bigger and bigger,
> All bread, butter, sugar, milk, taters, and beer.
> Take a fresh lease of life and commence a new era
> Mr. Banting's advice makes one long to begin—
> Drink claret and sherry, good grog and Madeira,
> Take four meals a day and—grow gracefully thin."

The passage of almost a century does not appear to have brought about any marked improvement in the art of slimming, and perhaps the old Roman custom (employed to a certain extent in this country around 1824, when Sir Astley Cooper popularized John Hunter's (1772) and Dukes's (1822) modification of what is now Ryle's stomach tube) of eating a hearty meal, pressing on regardless (gastronomically), then vomiting immediately afterwards, had certain advantages.—I am, etc.,

London, W.1. J. DOUGLAS ROBERTSON.

SIR,—May I suggest the use of Dr. R. D. Lawrence's simple diabetic diet (unweighed) card, or a card on the same lines, for the dietetic treatment of obesity? This card, which shows all the common and many of the rarer foods under such headings as "Forbidden" or "Allowed" (more or less *ad lib.*), finally shows a certain number of foods that must be taken in known amounts. A modification of the card gives (*a*) forbidden foods, a group including sugar, cakes, and several other items; (*b*) allowed *ad lib.*—tea, coffee, water, and certain other drinks, saccharin, etc.,; (*c*) proteins and fats—here all one need do is say "Normal rations"; (*d*) carbohydrates—(1) a group which may be taken *ad lib.*, (2) a group which should be taken in normal amounts only, and finally (3) there is Dr. Lawrence's last group of several common food items, each called a portion and each being about 10 g. carbohydrate. This last group includes potato (size of hen's egg), bread, milk (a tea-cup), etc. The only item one need weigh (at first) is bread (⅔ oz. (18.8 g.) = one portion). If one allows the patient 14 portions per day he (or more often she) makes his (her) selection from this group. By the use of such a diet obese people can join fairly easily in the ordinary family meals. They should weigh themselves weekly, and should aim to lose an average of 2 lb. (0.9 kg.) per week; if not doing so after two or three weeks they can raise or reduce their number of portions slightly. It has been suggested that one item—nuts—not specially excluded on the diabetic diet card should be excluded in the treatment of obesity, but in general their cost will forbid them to most people.

The card is obtained from Mesrs. H. K. Lewis & Co., London.

In using Dr. Lawrence's diabetic card one must of course delete such paragraphs as relate peculiarly to diabetics—e.g., reference to insulin.—I am, etc.,

Middlesbrough. BASIL LONGBOTHAM.

SIR,—Dr. H. L. Marriott's weight-reducing diet (July 2, p. 18) allows as many potatoes as the patient likes, but no fat or cheese. A variation of this diet which is equally successful and pleasanter for the patient is to forbid potatoes but insist that all the ration of butter, margarine, cooking fat, and bacon is eaten, as well as all the cheese which can be procured. Patients should also be told they must eat four meals or snacks daily, and if they find that as a result of the diet they are sleeping badly or are having nightmares they should have their largest meal as late as possible at night.—I am, etc.,

London, W.1. FRANKLIN BICKNELL.

Teaching Pharmacology in India

SIR,—I was much impressed with the report of the Medical *Curriculum Committee* on "The Training of a Doctor." Especially was I pleased to read the remarks on the teaching of pharmacology and therapeutics.

Having devoted now over 30 years to the teaching of pharmacology, and being the author of a standard book on pharmacology, materia medica, and therapeutics, I always realized the defect in the present system, and you were good enough to publish in the *Journal* of Sept. 11, 1937 (p. 552), my views on the teaching of pharmacology. I stressed the importance of teaching pharmacology and therapeutics together and also the necessity of allotting clinical beds to the teacher of pharmacology.

Recently the Medical Council of India appointed a committee to revise the medical curriculum, and I have been appointed chairman of the Committee on Pharmacology and Therapeutics. Your report has been of great help to us. I have issued a questionary to get the viewpoints of those who are engaged or interested in the subject. I shall be grateful if you could help me in getting the views of those interested in the subject in your country.—I am, etc.,

B. N. GHOSH.

Tolerance to Adrenaline

SIR,—The following case illustrates acquisition of a very high degree of tolerance and resistance to adrenaline, followed by complete loss of same after the drug had been withheld for a short period.

The patient, a man aged 51, has had spasmodic asthma for four years. He suffers from recurrent bouts of what can best be described as chronic status asthmaticus. These bouts last about a month. Before coming under my care he was taught how to administer subcutaneous doses of adrenaline to himself. Though restricted as to what was a safe dosage, he was urged by the severity of his symptoms to adopt "kill or cure" methods. On one occasion he injected 180 minims (10.5 ml.) of adrenaline hydrochloride solution (1/1,000) as a single dose. He remembers no subjective symptoms. When the patient came under my care he was using large quantities of the drug in divided doses—i.e., 3–4 minims (0.18–0.24 ml.)—every minute until relief of symptoms, perhaps 1 oz. (28.4 ml.) in all during a bad night. The injections sometimes brought on an occipital headache.

After the last prolonged bout came to an end the drug was withheld for a month, and during this time there occurred a remarkable loss of tolerance. When next I had occasion to use the drug I was agreeably surprised to find that a 15-minim (0.9-ml.) dose was effective. This caused the systolic blood pressure to rise from 125 to 175 mm. Hg in six minutes, together with a small rise in the diastolic pressure and the pulse rate. The next day a larger amount was necessary to relieve his asthma. It caused a most violent reaction (agonizing throbbing headache, rigor, and tachycardia), and even a 15-minim dose on the following morning caused a similar headache.

Thus a patient who had once taken a single dose of 180 minims of adrenaline hydrochloride (1/1,000) without subjective ill effects became intolerant to a dose of 15 minims when the drug was withheld for a month. There was no question of the needle being in a vein.—I am, etc.,

Dublin. E. DESMOND FLOOD.

Exchange of Doctors with U.S.A.

SIR,—Before the war there were some schemes in action for the exchange of doctors between hospitals in this country and the U.S.A. There is now a more widespread desire by doctors in this country to visit the U.S.A. This may often be facilitated by arranging for a regular exchange of doctors between medical schools and hospitals in the two countries. There seems to be some fear that making such an arrangement for an American doctor to work in a hospital here infringes the Acts governing medical practice here. This is not the case, for by Section 8 of the Medical Practitioners and Pharmacists Act, 1947, Parliament has made provision for the admission to the *Medical Register* of Commonwealth and foreign practitioners temporarily in the employ of hospitals in this country.

If a hospital is prepared to offer a postgraduate post to a qualified practitioner who is not registered here, it is desirable both for him and for the hospital that he should have the status of a registered medical practitioner as the holder of that post, and Section 8 enables him to become temporarily registered here for that purpose.

The procedure for temporary registration under the section is quite simple, and it is only necessary to add that a practitioner who is not a British subject must, of course, as a first step obtain permission from the Home Office to enter and to remain in the U.K. in order to do postgraduate work.—I am, etc.,

London, S.E.1. RONALD MACKEITH.

POINTS FROM LETTERS

Palpation of the Pancreas

Dr. N. S. FRASER (St. John's, Newfoundland) writes: Is it possible to palpate the pancreas in disease? The normal pancreas is soft and could not possibly be felt through the abdominal wall, but a diseased gland, swollen and congested, will be firm to the touch and has only a flaccid, empty stomach over it. The transverse colon does not cover it. Then there is the abdominal wall with its tense rectus abdominis which is liable to contract if the hand is not gently applied. The inscriptiones tendinae are above and below the area to be palpated, and so do not interfere with the palpation. With concentrated attention, a warm hand flat on the abdomen, and light pressure, gradually increased, one can feel the whole gland if it is swollen with disease. Then, on pressure with one finger, the patient will wince and say it hurts. Such has been my finding in the diagnosis of subacute pancreatitis, beginning with a personal experience, and I would like an expression of opinion from others. The spleen cannot be felt until it is diseased, and the same can be said of the kidney; so why not the pancreas?

Herpes, Varicella, and Liver Extract

Dr. L. KILROE (Rochdale) writes: With reference to the letters by Drs. James Rooth and M. Mansour (July 9, p. 99), I saw cases of herpes coinciding with attacks of chicken-pox in 1940 and 1946. Both occurred in adult males (aged 45 and 47). The herpes, in one case intercostal and in the other frontal, appeared 5-7 days before the chicken-pox rash. Incidentally, the injection of 2 ml. of "anahaemin" in the second case on the appearance of the herpes did not appear to modify the course of either the herpes or the chicken-pox. The eruption in the intercostal case was the worst I have seen in a case of shingles. In over 40 years of practice I can only recall one other case of severe chicken-pox in an adult, again a male, aged 52. Herpes was not present. I have not yet seen a case of herpes with chicken-pox in a child.

Creeping Eruption

Dr. F. ADAM THOMSON (Ipoh, Malaya) writes: With reference to the medical memorandum by Dr. J. P. Caplan (March 5, p. 396), a number of these cases came under my care while practising in Northern Rhodesia. Infection as a rule seemed to date from a South African holiday. All responded to the vigorous local application of oil of chenopodium to the advancing end of the weal.

Obituary

BRIAN RAIT-SMITH, D.A., F.F.A. R.C.S.

Dr. Brian Rait-Smith, anaesthetist and demonstrator of anaesthetics to St. Bartholomew's Hospital, died at St. Albans on July 14, aged 45. He was educated at Jesus College, Cambridge, and St. Bartholomew's Hospital. He qualified in 1929. Within six months of entering the department of anaesthetics as a junior he was promoted to senior resident anaesthetist, an appointment he held until he joined the honorary staff in 1937. He took the D.A. in 1935, and this year was admitted F.F.A. R.C.S. He was particularly interested in the anaesthesia of neurosurgery and thoracic surgery. As a resident he played an important part in the pioneer work of chest surgery, and until his death gave anaesthetics for the increasingly difficult procedures undertaken by thoracic surgeons and neurosurgeons. He published work on anaesthesia for cardiac surgery, particularly that of the patent ductus arteriosus, and his article on anaesthesia in neurosurgery is shortly to appear in a textbook. He also wrote on obstetric anaesthesia, and his own observations on trichlorethylene and curare were reflected in papers from his department. Before he became whole-time anaesthetist to St. Bartholomew's at Hill End Hospital he was anaesthetist to the British Postgraduate Medical School, the Brompton Hospital, and Papworth Settlement, and he had been consulting anaesthetist to the L.C.C.

To the surgeons with whom he worked and his colleagues in the department Rait-Smith's skill was a greatly appreciated constant among the many variables of operative surgery. The difficult work he undertook is proof of the high standard of his anaesthesia. He had all the properties of a first-rate anaesthetist—ability, cool-headedness, sharp clinical judgment, and an enviable amount of common sense. That he was always cheerful and courteous and never allowed his temper to become ruffled was remarkable in one who spent his life in busy operating theatres. His residents became his firm friends within a few weeks of their appointment, and his help in their later careers can be witnessed to-day by a score of successful anaesthetists. A hard worker, he never resented a call to the theatres at Barts, however inconvenient the hour the request was made. There was no "side" about Rait-Smith. He hated affectation, and was as skilful in his deflation of a self-important surgeon as in his discreet encouragement of a young surgeon or anaesthetist. All this he managed despite the subarachnoid haemorrhage he had in 1942, the significance of which he knew well, and two major operations in the following five years. He was so full of zest for life in spite of his ill-health that his death is a shock to his friends, who will all extend their sympathy to his wife.

A memorial service will be held in the church of Saint Bartholomew-the-Less, on Tuesday, July 26, at 12.30 p.m.

Dr. CHARLES SALKELD, who died in Bournemouth on June 7 at the age of 81, was for many years in practice as an ear-nose-and-throat specialist in that town. He was educated at Manchester Grammar School and served his time as an engineer before taking up medicine. After graduating B.A. with honours in classics in 1891, he had a brilliant career at Durham University. He won the Gibb Scholarship in pathology, the Dickinson Scholarship, and the Charlton Scholarship in medicine, all in 1896. He graduated M.B., B.S. a year later. After 12 years

of general practice in Leeds Dr. Salkeld decided to specialize in ear, nose, and throat work, and he studied at the Central London Throat and Ear Hospital, where he became a clinical assistant. He started specialist practice in Bournemouth in 1913, but in 1915 joined the R.A.M.C., in which he served at home and overseas for four years. He then returned to Bournemouth, where he was appointed to the staff of the Cornelia and East Dorset Hospital, Poole, and later the Cottage and Children's Hospitals at Swanage. He also operated for many years at the Victoria Home for Crippled Children. Dr. Salkeld had recently retired from active practice following a severe illness. He had had an unusually broad education in engineering, classics, and medicine. His interests were wide, and his range of accurate knowledge was a byword with his family and friends. Apart from all this Charles Salkeld had a personality and appearance which inspired confidence and respect. He had a quiet, cheerful disposition, and when he spoke it was usually to give a well-considered opinion. Small talk and making conversation were not in his line; and he disliked social functions, at which he seldom appeared. He was unostentatious, never pompous, and completely genuine. His loss will be keenly felt by many friends, relatives, and colleagues. He leaves one son, who is in practice as an ear-nose-and-throat specialist in Bournemouth.

Medico-Legal

LEGACIES TO HOSPITALS UNDER N.H.S.

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A lady made her will on June 18, 1948, directing the executors to divide the residue of her estate into eight equal parts and to give one part to the Cancer Research Institute and another to the Royal Cancer Hospital.[1] At that time, and when she died on June 23, 1948, both were charities, but before the will was proved the National Health Service Act came into force, on July 5, 1948, and doubt arose whether the right to receive the share of the residue left to the Institute was vested in the Royal Cancer Hospital or in the Minister of Health. Was the executor required to apply the shares to the board of governors of this teaching hospital under Section 60 of the Act, or to the Ministry, or were they undisposed of? These questions were brought to the Chancery Division for solution by the Ministry of Health, counsel admitting that the Ministry confessed itself unable to understand the Act. The Ministry desired elucidation of the Act for its own convenience.[2]

Mr. Justice Harman said in his judgment that he had expected to find some guidance in the Act on the destination of legacies to hospitals. He had read the Act section by section with a bewilderment which finally ripened into despair when the conclusion was forced upon him—a conclusion from which he could see no escape—that by some mischance the Legislature had so framed the clauses of the Act as to leave charitable legacies of this kind outside it. The Act in that respect was, he said, almost a miracle of ineptitude.

The question could not go to arbitration, for it was a matter of law and not of fact. The interest which was left by the will was excluded from the category of endowments, nor was it a right acquired for the purpose of carrying on the business of the hospital. As the legatees had survived the testatrix, the legacies could not have lapsed.

The bequest must be dealt with by a scheme brought into court by the Attorney-General in the ordinary way. In discussing costs, he said that the difficulty had been caused by the astonishing ineptitude with which Part II of the Act was drawn, and he saw no reason why the charities which took the other shares of the residue should pay for the omissions of the Legislature. He did not think he ought to order the Minister to pay the costs, but he ordered that they should come out of the two shares over which the difficulty had arisen.

Medical Notes in Parliament

TUBERCULOSIS IN SCOTLAND

Estimates for the Department of Health for Scotland and the National Health Service, Scotland, were considered on July 6 in the Scottish Standing Committee.

Opening the debate, Mr. WALTER ELLIOT drew attention to recent figures for the incidence of pulmonary tuberculosis in Scotland. The factual inquiry which the Secretary of State for Scotland had set on foot had not yet indicated the nature of its report. Would it be available before the House rose for the summer?

Mr. WOODBURN said the report would not be available. Many facts had been elucidated, but if they were to be published as they stood at present they would be misleading and in some cases alarming.

Mr. ELLIOT said that in the absence of information exaggerated figures held the field. He hoped it would be possible to bring out an interim report and that some parallel figures could be secured for England and Wales. Figures which he himself had given to the Committee last year had indicated that the good figures for tuberculosis were in the South of England and that as one moved to the North the figures increased. This was not conclusive, however, because when one came to Aberdeen the figures suddenly improved. Dr. Harry Rae, the medical officer of health for Aberdeen, had pointed out in his report for 1947 that, although in Scotland as a whole the death rate for pulmonary tuberculosis was 66 per 100,000, in Aberdeen it was 35. In Scotland generally there had been increases both in the number of deaths and in notifications. The number of deaths was 2,717 in 1939; 2,932 in 1945; 3,231 in 1946; 3,739 in 1947; and 3,417 in 1948. Notifications were 7,317 in 1945; 7,627 in 1946; 7,984 in 1947; and 8,010 in 1948, which was the highest figure in Scotland for 30 years.

The figures for non-pulmonary tuberculosis were improving That reflected success in the long campaign against bovine tuberculosis. In 1945 they were 18, which was higher than pre-war; 15 in 1946; 14 in 1947; and in 1948 they were down to 9. In Scotland the number of patients in institutions had risen from 4,253 in 1945 to 4,462 in 1948. The waiting-list had gone up from 1,600 in 1945 to 2,500 to-day. Yet there were still in Scotland 572 beds which because of lack of staff could not be used. Dr. Harry Rae attributed part of the favourable position of Aberdeen to the fact that there were enough beds available there.

At the recent Harrogate conference a Glasgow doctor had spoken of a large increase in the waiting-list there and drew attention to an increase in the proportion of notifications among children under 15—in 1945 it was 9.3%, but in 1948 it was 18.4%. Glasgow used to have its own tuberculosis organization. Now the responsibility had moved to the Glasgow Regional Board. The National Association for the Prevention of Tuberculosis had advised regional hospital boards to set up a permanent tuberculosis committee. He did not know to what extent that advice had been carried out in Scotland.

A more extended use of B.C.G. vaccine might be of advantage and might help to stop the wastage of nurses in tuberculosis institutions, which rose as high as 65%. But isolation must always remain one of the main weapons for dealing with the white scourge. The number of active cases of tuberculosis on the waiting-list for houses in Glasgow was 437 in 1945 and in 1948 was 593. The Secretary of State must regard this as a matter of urgency. In some way or another the 500 beds which were empty in sanatoria should be brought into use. Vigorous campaigning by the Secretary of State would obtain an increase in the number of nurses for sanatoria.

Some post-war deficiency in nutrition was perhaps responsible for part of the increase. The intake of calories per head was less than it had been before the war. People in Glasgow, although badly housed, had before the war spent more money on food. Now they could not get more food than anyone else. It might be that somehow a more active tubercle infection had

reached the country. The great influx from the Continent, the influx of Poles, might have something to do with that.

Changes in Incidence

Mr. WOODBURN said the main increases had taken place in districts where the Poles had not been. The incidence of tuberculosis was very high in Southern Ireland, but there never had been a smaller importation from Southern Ireland than in the period when tuberculosis in Scotland had increased. The fall in deaths from non-pulmonary tuberculosis was from 705 to 426. Notifications of tuberculosis had gone up by a third compared with the five years before the war. But a comparison between notifications to-day and pre-war notifications had no value except to show that the medical profession was more alert to deal with the incipient disease. The number of notifications gave no indication of the reason for the increase in deaths.

Investigations by the Committee which he had set up had revealed how difficult it was to reach any sound conclusions. Deaths from pulmonary tuberculosis had been rising in Scotland but not in every place. The picture Mr. Elliot had given of children under 15 was not quite accurate; actually the number of cases had decreased slightly even when compared with the pre-war figures.

The situation could not be explained by any figures available at the present time. Because of this he thought it would be unwise to publish figures which might create speculation and alarm. In the worst places in Scotland the incidence was 110 per 100,000, and in the best places a little over 10 per 100,000. Congested living conditions still had a great deal to do with the spread of the disease, and therefore they should concentrate on segregation. So far as any distinction could be drawn it was between congested old towns and country areas, yet Ross and Cromarty was a bad area.

He had taken steps to get an additional 1,000 aluminium houses so as to free houses suitable for families where tuberculosis was present. The Department had also been able to make an additional 500 beds available since the beginning of 1948. It had put 50 more full-time nurses and 350 part-time nurses on to this work. Streptomycin was available in all cases where it was suitable for use. B.C.G. would shortly be available for use in Scotland for contacts. It was true that Scotland was still going backwards in regard to tuberculosis, and that tendency had not altered this year. The mystery was that they were not going backward in every place. The problem had been narrowed down, and the Committee under the National Health Services Council was pursuing this matter vigorously.

Mrs. CULLEN suggested that Mr. Woodburn should consider moving elsewhere aged and infirm persons who did not require trained nursing personnel. This would clear some wards so that the trained nurses could be used to greater advantage.

Commander HUTCHISON said a more extended use might be made of health visitors to keep cases of tuberculosis under observation. There were four mass radiography units in Scotland, and it would be helpful if there were more.

Mr. HUBBARD urged that a campaign should be started by the Government giving information to every individual about the causes of tuberculosis and the means of preventing its spread.

Position of Tuberculosis Officers

Mr. GALBRAITH urged Mr. Woodburn to ask the Committee to issue some sort of report at the earliest possible moment. He was doubtful whether patients would continue to get the best possible treatment if tuberculosis officers were classified as senior hospital officers and not as specialists. This fear had been expressed at the B.M.A. meeting at Harrogate. They needed to attract the most able doctors to the study of tuberculosis.

Mr. MATHERS said doctors with whom he had discussed the rise in the incidence of tuberculosis had suggested that the conditions of life of young people, and particularly young women, were important. In his constituency young people left home early in the morning to go to work by bus, had hurried meals, and were out dancing till midnight three, four, or five nights a week. As a result they became debilitated and an easy prey to tuberculosis. A great deal of the incidence could be prevented by instruction to people about the way they sapped their energy and reduced their resistance. The highest incidence of tuberculosis was between the ages of 15 and 25.

Replying to the debate, Mr. THOMAS FRASER said Mr. Woodburn was anxious that as much information as possible should be made available to health authorities and Members of Parliament as well as to the medical profession. The Committee which had been set up must conduct its researches thoroughly before reporting. It might be that there was a deficiency in diet, and the Committee would consider that. The diet of Scotland, however, was no different from that of England and Wales. The number of notifications in children under 15 had gone up a little, perhaps because of mass radiography, but the death rate of those under 15 was going down. They must not imagine that the position was improving in the whole of England and Wales. The town where figures had worsened most in the last 10 years was Jarrow. In 1938 Jarrow had 78 deaths from tuberculosis per 100,000 population. In 1947 the figure was 110. Glasgow was second in the list with 85 deaths in 1938 and 105 in 1947. Next came Dundee with 62 deaths per 100,000 in 1938 and 82 in 1947. The worsening was where poverty had been greatest in the last 20 years.

Concluding, he pointed out that the general health of Scotland was better than it ever had been before. The suggestion made by Mrs. Cullen that nurses now looking after old people should be made available for cases of tuberculosis was well worth making and had not been overlooked by the Secretary of State or by the hospital boards.

The Committee then adjourned.

General Medical Council

Sir HARTLEY SHAWCROSS moved on July 12 the Second Reading of the House of Commons (Indemnification of Certain Members) Bill. He explained that it dealt with a possible infringement of the laws relating to offices of profit under the Crown. These laws in the main were embodied in the Succession to the Crown Act of 1707 and were obscure. The view had been taken that to be held under the Crown an office did not necessarily have to be subject to any continuing control by the Crown in its exercise. Where there was any expectation of payment going beyond a fair reimbursement of expenses incurred, such payment would make the office one of profit. The attention of the Government had been drawn to the position of certain members who had been nominated by his Majesty as members of the General Medical Council. The King, on the advice of the Privy Council, nominated five members of the Council to hold office for a term not exceeding five years. Provision was made for the payment of fees to members, and in practice they were paid a sum of 5 guineas in respect of each attendance. They were not paid out of moneys provided by Parliament but out of moneys collected by the medical profession from registration fees. That the actual emoluments of an office were derived from sources other than public funds was not held by the Government to be a criterion of whether an office was one of profit under the Crown. During the present Parliament two Members of the House had been nominated to the Council on the advice of the Privy Council. Previously many members had sat on the General Medical Council without anyone suggesting that there might be an infringement of the Statute of 1707. Penalties against these members should now be statute barred and they were not included in the Bill.

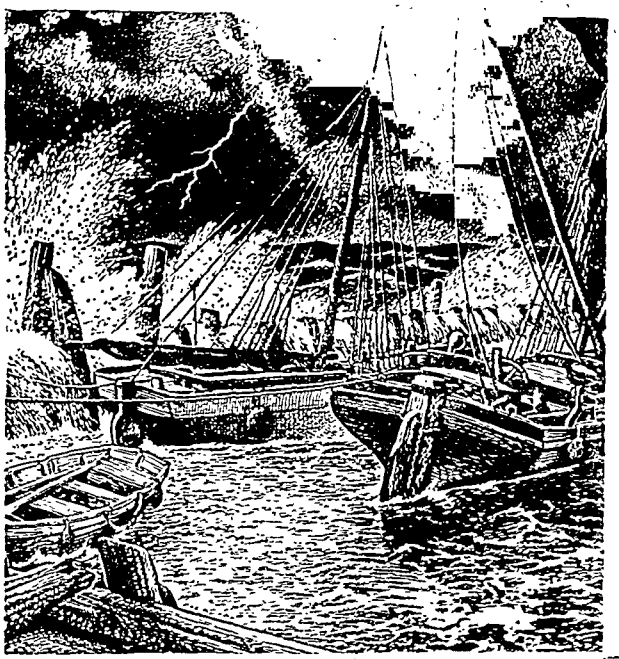
The two members appointed in the lifetime of the present Parliament had been appointed and held their office in good faith on the basis of many precedents, but there was no doubt that they had been appointed to an office of profit under the Crown. Mr. John Hynd had never acted in the office, because before he took any part in the proceedings of the General Medical Council it occurred to him that there might be some question of impropriety in holding the office. The two Members concerned must vacate the appointments but ought not to be penalized for having held them, and this Bill sought to indemnify them. The Government did not seek to constitute the office into one not of profit, and did not propose to legislate to say this should not be an office which members must not hold. It would be the future policy that no member should be

DISPRIN

Soluble, neutral and palatable aspirin tablets in stable form

GREAT DIFFICULTY *has hitherto been met* in providing soluble aspirin in tablet form which will remain stable under ordinary conditions of storage. This difficulty has now been overcome.

Disprin has *all the valuable qualities of calcium* aspirin—analgesic, antipyretic and anti-rheumatic. Since it is soluble, it is more rapidly absorbed and consequently more speedy in its clinical effect. Since it presents *aspirin in the form of* its calcium salt, it is more sedative. Moreover, it does not act as an irritant to the gastric mucosa, because, unlike ordinary aspirin, it is soluble.



Disprin tablets readily dissolve in water to form a substantially neutral palatable solution.

Bottle of 26 tablets, price 2/- including Purchase Tax.
On prescription Disprin is free of Purchase Tax.
Clinical sample and literature supplied on application.

STABLE, PALATABLE, NEUTRAL
SOLUBLE CALCIUM ASPIRIN

Protecting the traveller from the rigours of motion sickness

'VASANO' is a proven remedy for all forms of travel sickness — land, sea or air — and is also widely prescribed for the treatment of Ménière's disease.

'Vasano' contains hyoscine, hyoscyamine and camphoric acid in balanced proportions affording optimal central and peripheral action.

Hyoscine, acknowledged as one of the most effective single agents for the prevention of travel sickness, exerts a sedative influence on the higher centres and is a parasympathetic depressant, while hyoscyamine acts peripherally upon the vagus and produces a more prolonged effect.

LIMITED
LOUGHBOROUGH, LEICESTERSHIRE

qualified to hold the office. Sir Hartley went on to refer to a case of a different character in which another member was concerned and for which the Bill also proposed indemnification.

Mr. R. A. BUTLER said that, in view of the fact that under the rules of the General Medical Council fees and reasonable travelling expenses could be paid, there was no doubt that the case of the two members ought to be covered by a Bill such as that before the House. It was intolerable that members should be in a position where they might at any time unwittingly contravene the law.

The Bill was then read a second time without a division, passed through Committee without amendment, reported, and read a third time.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Sir Maurice Alan Cassidy, Physician-in-Ordinary to the King, has been elected an Honorary Fellow of Clare College

David Robertson Smith, M.B., B.Chir., has been elected to an Elmore Medical Research Studentship, from May 1.

In Congregation on June 21 the degree of M.D. was conferred on T. S. Hindle.

In Congregation on June 22 the degree of M.B. was conferred, by proxy, on J. Ff. Edwards.

UNIVERSITY OF GLASGOW

The following medical degrees were conferred on July 9:

M.D.—A. Allison, W. Chambers, W. W. Douglas, W. S. Linton, T. M. Paterson.

Ch.M.—J. Cuthbert, A. W. Kay.

M.B., Ch.B.—Kathleen M. Adams, Marion K. Aitken, A. G. Anderson, G. Anderson, I. N. O. Asinobi, H. B. M. Auld, Anne R. Austin, A. G. Baikie, M. McA. Baird, R. Bankier, G. I. Barrow, N. J. B. Bowie, A. H. Boyd, A. Brodie, I. D. Brown, T. Brown, J. Buchanan, Millicent E. Burns, R. K. Burt, A. H. P. Carswell, Mary S. Christian, J. H Cowie, I. D. Cullen, T. A. Cunningham, D. Davies, F. W. G. Deighton, D. A. T. Dick, J. F. Dick, Grace C. Dunbar, R. Erskine, J. Forsyth, J. Frame, P. G. Gaskell, R. M. Gibson, J. C. Gillespie, J. S. Gillespie, B. Green, R. Greenhill, A. J. Hale, A. M. Halliday, P. Hay, J. C. M. Henderson, G. P. Henry, W. F. Heslin, Elspeth C. Higgins, Margaret I. Hill, D. S. Hogg, D. W. G. Honeyman, R. McD. Hosie, Janet L. P. Hunter, S. W. Hind, Christina M. Jack, J. B. Johnson, D. G. Kay, Mary W. Kellock, A. E. D. Kennedy, A. S. L. Kennedy, J. Knox, A. Kyle, A. S. McC. Lamont, J. G. Leitch, S. G. Leitch, D. W. Leslie, G. H. Lowther, S. G. McAlpine, Sheena E. McCoshim, D. MacDonald, D. G. MacDonald, Sheila C. MacGregor, N. J. McKellar, J. V. McKenzie, Ruth B. McKenzie, D. McKirdy, J. R. Maclean, Ethel E. M. McLellan, Cynthia J. McPherson, W. McQuater, R. K. McRae, G. T. Mair, Maureen A. F. Malcolm, Hazel G. Mansell, Elizabeth L. Millar, T. M. Miller, A. T. Mitchell, J. N. S. Mitchell, J. J. E. D. Mitchell, J. Moodie, J. B. Morris, Sylvia Morris, T. P. O'Hea, H. W. J. Park, L. R. Parker, D. C. Pendrigh, A. J. E. Pollock, W. M. Prentice, J. R. Raeside, A. M. Reid, A. W. Reid, J. M. Reid, B. J. Reilly, A. A. Robertson, A. K. Ross, P. Roughead, J. R. Roy, T. S. Russell, T. C. Rutledge, Jessie L. Sharp, A. Silver, R. G. Sinclair, G. D. Smellie, C. McP. Smith, Joan E. Smith, W. D. Smith, Sheila W. Soote, R. H. Stewart, W. O. Stewart, D. S. Strachan, G. H. Swanson, Vera Taylor, Elizabeth D. M. J. Thomas, A. S. Watson, Sheila M. Whiteside, J. R. M. Wilson, R. B. Wilson, W. Wilson, G. B. Wylie, G L. Wylie, Mary W. Young.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—R. A. J. Holmes-Ievers, P. J. Mullaney.

M.B., B.Ch., B.A.O.—D. W. Beckett, W. G. T. Bell, F. G. O. Burrows, Dorothy J. Cartmill, C. G. H. Charlton, R. P. A. Coffey, R. S. Crone, W. P. C. Deely, E. W. Eppel, B. B. Fazackerley, T. G. Feeney, [1] [2]Audrey M. Franklin, [1]R. J. M. Fry, [2]Agnes C. Good, C. Harris, Wilhelmina Hutchinson, H. P. Isaacson, [1]Beatrice P. Karmel, S. M. Laird, [1]Thelma H. W. Morks, Sybil E. K. Oulton, [1] [2]Eleanor B. Outon, W. Pappenheim, L. R. Robinson, Kathleen C. Rogers, Eva Roith, C. F. Ross, [1]Stephanie Saville, [1]S. B. Sloan, M. D. M. Staunton, B. S. Telford, [2]W. D. H. Troughton, E. R. D. Williamson, Oonagh D. Wray, R. S Young.

M.B.—Reva Berstock, S. C. Blake, Evelyn Browne, Joan I. Buchanan, L. J. Clein, K. C. Finkel, R. C. Gray, O. H. Killen, E. B. McHugh, Sheilagh M. McHugh, J. C. McLean, W. D. McNaul, T. T. E. Michael, R. Nelson, J. P. Nixon, V. P. O'Sullivan-Quinn, Ruth M. Perrott, Frances E. Russell, R. N. Siberry, A. A. Sweeney, Annie M. G. Troughton, F. A. Walkey.

M.B., B.A.O.—Vyvyan I. K. Johnston.

B.Ch., B.A.O.—Mabel M. H. Hodgins, [2]B. A. McC. Thompson.

B.Ch.—W. D. H. Powell, Gwendoline G. L. Poots.

B.A.O.—D. L. Cowan, Marisa A. O'Keeffe.

[1]With second-class honours in medicine. [2]With second-class honours in surgery.

UNIVERSITY OF DURHAM

In Congregations held on July 1 and 2 the following medical degrees were conferred:

M.D.—H. M. Dixon, D. G. French, S. Josephs, F J. Prime, M. Walton, *C. A. H. Watts, *W. E. Hick, *C. Strang.

M.S.—James Watt.

M.B., B.S.—C. F. Anderson, J. A. Anderson, G. W. Bainbridge, Jean M. Bainbridge, S. M. Bell, G. S. Black, Sheila M. Bowerbank, F. W. B. Breakey, Hugh Brown, Eleanor J. Carmichael, Barbara W. Cooke, L. D. J. Coore, D. Coulthard, B. W. D. Crawford, Elizabeth Daley, H. Davison, H. D. Davison, Mary Dixon, Joyce Dodds, L. B. Fleming, Robina M. Forsyth, Vera M. Gallagher, Dorothy B. Gilmour, J. B. Glaholm, Pearl Goddard, H. Gossmann, Eve R. Halson, J. Harper, Maureen McG. Henderson, J. P. Hurley, J. E. M. Hutchinson, W. D. Kerr, E. G. Knox, G. E. Langley, Sheila Langley, L. J. Levene, Norma D. Lill, J. McCormack, J. R. McGregor, I. F. McNeill, Joan E. Maddison, J. S. Makepeace, R. W. Mayes, Ann Moffatt, Sylvia A. Moss, G. A. Nemeth, Muriel K. Nicol, P. G. F. Nixon, Ruth Parkinson, Dorothy A. Percy, A. B. Piper, Ann F. Pumphrey, Greta L. Reid, W. T. Richardson, Margaret W. Rodham, N. R. Rowell, C. M. Scott, Gillian E. Sladden, A. S. Todd, C. G. Tulloh, H. P. Tulloh, J. Turnbull, W. Turnbull, Constance N. Vernier, Elizabeth Wales, E. W. Walton, A. J. Watson, L. L. Williams, R. K. Epstein, *G. H. N. Bates, *J. M. H. Hopper, *Kathleen S. Reed, *Winifred J. Skinner.

In absentia.

UNIVERSITY OF LONDON

The following candidates at the London School of Hygiene and Tropical Medicine have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—A. O. Abushamma, René F. Barclay, S. Y. Bhagwat, *H. Binysh, J. F. E. Bloss, L. B. De Lanerolle, H. A. Dharamsey, J. E. G. Earle, L G. Eddey, T. P. Eddy, S. J. Evans, A. F Fowler, *A. W. Gilks, A. H. Griffith, R. F. Guymer, W. G. Harding, C H. Hoskyn, Esther Jackson, S. A. Jones, W. A. Karunaratne, M. S. Kataria, D. A. Kuruppu, M. G. Langdon, P. A. Lee, R. N. C. McCurdy, J. C. McDonald, T. C. Macdonald, J. J. McNair, J. R Mayers, Isobel S. Mowat, G. M. O'Donnell, C. E. Phillip, Isabella M. Pinkerton, J. St. C. Polson, R. H. Pratt, P. G Roads, C. L. E. H. Sharp, R. A. G. Smith, D. G. Snell, W. B Thorburn, P N Wilson.

*Awarded a mark of distinction.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—[1]J. Curry, B. H. Dawson, [2]T. B. S. Dick, [1]F. Howarth, [2]W. E. Kershaw, F. Latham, F. S. Mooney, [2]P. H. Renton, [2]E. P. Samuel, D. Sutton.

Ch.M.—R. H. Sewell.

FINAL M.B., Ch.B.—[3] [1]E. A. Allcock, [3] [1]Jean A. Lovatt, [2]W. J. Metcalfe, Mary A. Adlington, Anne R. Barlow, [1]Jessie M. Beard, T. B. Benson, K. Bloor, Margery F. Blumberg, F. Bottomley, Jean M. Breakell, N. C. Brown, K. D. Buckley, P. M. L. Burne, F. R. Calvert, [1]Betty Carruthers, C. Cohen, P. Cuff, R. D. Currie, S. Dobson, Audrey E. Draycott, P. D. Drinkwater, [4] [1]J. B. Eagles, G. Fildes, Edith H. Grundy, G. Hudson, A. G. Jackson, G. Kettlewell, Kathleen M. Lord, I. Macpherson, Lavinia M. Mallott, Marguerite Midgley, Barbara Oldham, F. W. Oliver, Christine M. Parish, Marjorie E. Petch, N. E. Quin, Regina Reif, Marjorie Rivers, A. D. Robinson, M. Sandler, Jeanette S. Shankland, D. P. Shepherd, Rosaleen E. Singer, I. A. Susman, R. M. Thomson, T. A. J. Thorp, Margaret R. Thoseby, Barbara J. Walker, Kathleen R. Walker, T. H. Whitaker, Olive C. Wilks, D. H. Yates. *Part I:* B. L. Alexander, D. Ashworth, R. D. Atherton, Constance M.

Bevan, G. Bills, Flora M. Bisset-Smith, S. M. Broman, P. Burgess, J. C. Canney, P. W. Carnie, Muriel D. Carr, G. Clarke, Barbara M. Couldwell, D. Davies, B. Didsbury, J. Ellis, E. J. Epstein, J. D. Evans, M. C. Flasher, M. Fox, G. Garrett, G. R. Gates, F. G. Hardman, J. K. Harris, T. V. A. Harry, B. Higgins, R. Hinchcliffe, J. T. W. Howe, G. Howitt, T. R. Hunter, J. E. Kench, W. Kerns, P. B. Lees, B. J. Leonard, M. A. Lerner, P. F. Lister, W. H. Lyle, Maria R. Mackay, B. E. Marks, A. W. Moule, J. T. Newton, A. S. Nicholas, G. W. H. Oldfield, Nancy Parkin, D. W. Preston, R. Price, G. V. Purnell, K. L. Purnell, M. B. Raby, Carolyn C. Rigby, Gertrude H. G. Robinson, J. Robinson, Dora M. J. Rosbotham, D. S. Rosenberg, Kathleen M. Rushton, R. Schofield, H. Selcon, Lorna J. Shankland, S. Shubert, A. Sippert, D. M. Somerville, S. Stead, G. Sullivan, Hazel W. Symon, C. F. H. Vickers, Margaret R. Walley, G. M. Watson, Sheila M. E. West, W. A. Whittaker, B. A. Wolfenden, D. Wolman, A. M. Womack.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*Part I:* M. M. Lidgate, A. Model.

[1]Gold medal. [2]With commendation. [3]Second-class honours. [4]*Distinction in medicine.* [5]*Distinction in surgery.* [6]*Distinction in* hygiene and preventive medicine.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

On the recommendation of the Council of the Welsh National School of Medicine the trustees of the Mansel Talbot Endowment have appointed Fred Grundy, M.D., D.P.H., D.P.M., to the Mansel Talbot Chair of Preventive Medicine in the Welsh National School of Medicine. Dr. Grundy has been medical officer of health to the Borough of Luton since 1937.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—C. V. Donnelly, J. G. P. Jones, Edith M. McConnell, P. L. Robinson, W. Sircus, A. H. Williams.

MASTER OF RADIOLOGY.—*Part I:* J. Ainsworth, Constance M. Davis. *Part II:* J. F. Doherty, W. J. L. Francis, B. B. Harrison, W. Kulke, J. P. MacLaughlin, A. S. Whitehead, F. B. Wright.

M.B., Ch.B.—[1] [2]Brenda M. Heathcote, [1] [2]W. B. Jennett, [1] [2]J. C. Richardson. *Part III (Old Regulations):* Margaret Addison, D. U. Bloor, Rosemary J. Bolam, R. Bradshaw, K. W. Brewster, P. Burrows, Anthea M. Bushby, Jean O. R. Carmichael, Mary I. Charlesworth, Jean M. Collins, Beryl C. Davies, Catherine M. Durkin, W. Ellis, O. L. Evans, Shelagh J. Fair, G. H. Fletcher, R. I. Green, I. W. Griffith, Margaret E. Hall, D. B. Hargreaves, J. F. Hobson, W. M. Hunter, P. Hurst, [2]Margaret L. Johnson, J. L. Jones, R. E. Jones, R. H. Jones, Margaret Knox, Margaret A. Lees, Halina Z. Lewinska, D. H. Lloyd, Marcia McArthur, Audrey M. L. Owens, Ethel Owens, W. R. Parry, S Plumpton, Sheila M. Pope, Ursula C. Pope, J. N. Rimmer, R. K. Rimmer, Myfanwy R. H. Roberts, E. Rogansky, H. U. Shaw, Pauline R. Sullivan, J. C. Taylor, R. P. Watkins, D. L. Williams, J. A. Williams. *Passed in Separate Subjects:* D. J. Adams, Dorothy M. Broadhurst, and J. S. Endbinder (Surgery, Obstetrics and Gynaecology); Lily I. Chesham and C. Griffith (Medicine, Obstetrics and Gynaecology); A. J. Cunningham, Betsy E. Davies, E. J. J. Davies, and B. J. Maxwell (Medicine, Surgery).

DIPLOMA IN PUBLIC HEALTH.—D. J. Cusiter, Elinor M. Evans, S. Ghousuddin, K. G. Koshi, D. A. W. Nugent, G. P. Reed, H. D. Sutherland, W. F. Wille.

[1]With second-class honours. [2]With distinction in obstetrics and gynaecology.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a special meeting of the Council held at the College House on July 5 with the President, Sir William Gilliatt, in the chair, the Honorary Fellowship of the College was conferred on Sir Henry Dale, O.M., F.R.S., President of the Royal Society of Medicine, and on Professor J. E. Heyman, of Stockholm.

The following were admitted to the Fellowship of the College: H. L. Sheehan, D. F. Standing.

The following were admitted to the Membership of the College: G. C. Brentnall, J. H. Maloney, C. Mukherjee, E. I. Ostry, H. Renton, D. B. Stewart, E. G. Zacks.

The President formally presented the prize for an essay on "The Physiology of the Third Stage of Labour" to Dr. Jean R. C. Burton-Brown; the prize was shared equally with Dr. David Shaw, whose essay was on "The Management of the Third Stage of Labour."

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 2. [No. 26

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each Infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)

Rate per 1,000 total births (including stillborn)			24					43		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales, Eire, and Northern Ireland

EPIDEMIOLOGICAL NOTES

Food Poisoning in Yorkshire

On July 2, 332 cases of food poisoning occurred among school-children at Settle, Yorkshire. *Salmonella typhi-murium* was isolated. The symptoms were fever, headache, prostration, bellyache, vomiting, and diarrhoea. In the mildest cases the symptoms were constitutional rather than related to the abdomen, and were attributed at first to the heat of the sun or in one case to teething. Most cases were mild to moderate, but, in the more severe, frequent stools were passed containing blood and mucus. There were no deaths. On June 30 Farm A, which supplied school milk, was short of the required quantity and bought some from Farm B. A cowman at Farm B had been ill with diarrhoea and vomiting during the week but had carried on with his work: it was hay-making time and everyone was very busy. The milk from Farm B was stored overnight in a refrigerator and distributed with milk from Farm A to schools in Settle Rural District on July 1. There were no cases in Skipton Rural District, which received unmixed milk from Farm A, and no cases on Farm A's milk round. There were three mild cases on Farm B's milk round and two moderately severe ones on the farm itself. *Salm. typhi-murium* was isolated from a case on Farm B, from a sample of the school milk supplied on July 1, from four out of six empty but unwashed milk bottles, and from the stools of selected cases among the school-children.

Poliomyelitis

An increase in the number of notifications of poliomyelitis has been reported for four consecutive weeks. The trend of this disease is one of increasing incidence until the autumn, and it seems likely that a large outbreak, such as was experienced in 1947, must be expected. The number of notifications for the 24th to 26th weeks were 31, 44, and 56 in 1947 compared with 35, 48, and 80 of this year.

During the week the largest returns were Cornwall, Camborne–Redruth U.D. 9; Yorkshire West Riding 9; Middlesex 8; London 6 (Lewisham 3); Lancashire 5; Devonshire 4; Oxfordshire 4; Essex 3; Hertfordshire, Hatfield R.D. 3; Gloucestershire 3. In Cornwall the disease has chiefly attacked young children, and three-quarters of the first 12 notifications were of children under 5.

Notifications in the week ended July 9 were poliomyelitis 73 (80), polio-encephalitis 4 (1). (Figures for the previous week are in parentheses.) Multiple cases (poliomyelitis and polio-encephalitis together) were reported from the following counties: London 6 (6), Cheshire 2 (2), Cornwall 5 (9), Devon 11 (4), Gloucestershire 3 (3), Hertfordshire 4 (3), Lancashire 5 (5), Middlesex 5 (9), Nottinghamshire 3 (0), Southampton 2 (1), Warwickshire 3 (1), Yorkshire West Riding 10 (9), Glamorgan 3 (1).

The general picture of incidence is very different from what it was at the corresponding period in 1947. In 1947 the early rise in incidence was chiefly in the more densely populated parts of central England, with additional foci in north-west Lancashire (Barrow) and in Tyneside. This year, although there has been some increase of incidence in the central parts, the chief increases have been in the west and south. Notifications in the West Riding of Yorkshire have risen to 10 (9), but otherwise the north has remained remarkably free from the disease. Another difference between 1949 and 1947 has been high attack rates in relatively small and isolated communities.

Discussion of Table

In *England and Wales* there was an increase in the number of notifications of measles 121, whooping-cough 79, acute pneumonia 42, and acute poliomyelitis 32; decreases were recorded for scarlet fever 106, paratyphoid fever 18, and dysentery 17.

The largest increases in the notifications of measles were Warwickshire 103 and London 101, and the largest decrease was Kent 193. The largest variations in the local returns of whooping-cough were increases in Lancashire 56 and Warwickshire 25 and a decrease in Suffolk 25. The only considerable rise in the number of notifications of scarlet fever was 20 in London, and the largest falls were Lancashire 34, Yorkshire West Riding 33, and Warwickshire 28. There was no great change in the local returns of diphtheria, but the disease was slightly more widespread, and four more counties reported a case than in the preceding week.

A further 9 cases of paratyphoid fever were notified in Durham; the number of notifications in the three preceding weeks were 26, 28, and 15. The only important centre of dysentery was Lancashire 22 (Liverpool C.B. 20).

In *Scotland* decreases were recorded in the number of notifications of measles 121 and scarlet fever 29, while increases were reported for dysentery 18 and diphtheria 13. The rise in incidence of diphtheria was spread throughout the country. The chief centres of dysentery were Glasgow 32, Edinburgh 10, and Midlothian county 5.

In *Eire* increases were reported in the number of notifications of measles 76 and diarrhoea and enteritis 16. The increased incidence of measles was general throughout the country except in Dublin C.B. The largest returns were Dublin C.B. 136, Kerry, Listowel R.D. 47, Cork C.B. 29, and Tipperary, Tipperary U.D. 21. An increase of 10 in the notifications of diarrhoea and enteritis occurred in Dublin C.B.

In *Northern Ireland* a decrease occurred in the number of notifications of measles 16 and scarlet fever 28, while an increase of 8 was recorded for diphtheria.

Week Ending July 9

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 946, whooping-cough 2,183, diphtheria 103, measles 5,571, acute pneumonia 346, cerebrospinal fever 39, acute poliomyelitis 73, dysentery 59, paratyphoid 32, and typhoid 5. Of the 477 cases of food poisoning 332 were notified in Yorkshire West Riding, Settle R.D. (see above).

Medical News

Leverhulme Research Fellowships

The advisory committee has recommended and the trustees of the Leverhulme Research Fellowships have approved the following awards for research tenable for periods up to two years: *Fellowship*, Dr. H. M. Woodman, chemotherapeutic treatment of filariasis in Southern Sudan. *Research Grants*, Dr. G. W. Harris, neural control of the pituitary gland: Dr. D. A. McDonald, the role of the hypothalamus and brain-stem in the regulation of the autonomic nervous system. Application forms and further information may be obtained from the secretary, Leverhulme Research Fellowships, 7, Bedford Row, London, W.C.1.

Hire Purchase Facilities

The Medical Sickness Finance Corporation, whose chairman is Sir Cecil Wakeley, has been incorporated as a private limited company to give hire purchase facilities to medical and dental practitioners wishing to buy cars and equipment. The corporation is a subsidiary of the Medical Sickness Annuity and Life Assurance Society, Ltd. Its address is 7, Cavendish Square, London, W.1.

Society of Medical Officers of Health

Dr. H. C. Maurice Williams, O.B.E., medical officer of health for Southampton, has been elected president of the Society of Medical Officers of Health for the year 1949–50.

Gift of Medical History Journal

Mrs. Josiah C. Trent, of Durham, North Carolina, U.S.A., has instituted an annual gift of 250 one-year subscriptions for the *Journal of the History of Medicine and Allied Sciences*. They will be allocated to all medical schools in the U.S.A. and Canada. Recipients are to be selected from among those in the graduating class who have shown an interest in the cultural aspects of medicine. The late Dr. Josiah C. Trent was a founder of the journal and a member of its board of editors. Recently the journal came under the official sponsorship of Yale University School of Medicine.

International Congress of Otolaryngology

The congress was opened by the Duchess of Kent on July 18 at the Great Hall, King's College, London. Thirty-nine countries were represented.

Tribute to Sir Gordon Gordon-Taylor

The April issue of the *British Journal of Surgery* is dedicated to Sir Gordon Gordon-Taylor, K.B.E., C.B., F.R.C.S., consulting surgeon to the Middlesex Hospital, and includes an appreciation of his work in the field of surgery since he entered the Middlesex Hospital as a student in 1898.

Actonian Prize

The managers of the Royal Institution have awarded the Actonian Prize of one hundred guineas for the year 1949 to Sir Alexander Fleming, F.R.S., for his paper published in 1945 entitled "Penicillin—Its Discovery, Development, and Uses in the Field of Medicine and Surgery." The prize has been awarded every seventh year since 1838 under a trust established in that year by the late Mrs. Hannah Acton.

Lecturing in Germany

Dr. G. M. Findlay, editor of *Abstracts of World Medicine*, is lecturing in Germany at the invitation of the Foreign Office on recent advances in knowledge of virus diseases.

Council for Welfare of Handicapped Persons

Lord Rushcliffe has resigned, owing to ill-health, the chairmanship of the Ministry of Health Advisory Council for the Welfare of Handicapped Persons. The Minister has appointed Mr. Edward Evans, M.P., formerly vice-chairman, in his place. The Minister has also appointed Alderman Mrs. L'Estrange Malone, chairman of the Welfare Committee of the London County Council, to be a member of the Advisory Council in place of Councillor Douglas Prichard, who has resigned.

Laboratory Examinations

The Ministry of Health states that laboratory examinations of pathological material relating to outbreaks or suspected outbreaks of infectious disease, other than those occurring in hospitals in which a pathologist is working, should be referred to the Public Health Laboratory Service where possible and not be undertaken in hospital laboratories. If the Public Health Laboratory Service is not available within a reasonable distance, these examinations should be undertaken by hospital laboratories and charged to hospital funds. Any information of epidemiological interest should be reported to the Public Health Laboratory Service and to the medical officer of health concerned. Examinations of specimens taken from material not of human origin should be undertaken by hospital laboratories only by arrangement with the Public Health Laboratory Service, the latter meeting the cost. Unless the hospital wishes, this arrangement need not apply to samples of water, milk, food, etc., supplied to the hospital for its own use. The Public Health Laboratory Service will not be responsible for the payment of fees to a pathologist in private practice except where he has been called in by arrangement with that service. The term "infectious diseases" excludes venereal diseases and tuberculosis in institutional cases. Examinations in these cases are normally a hospital responsibility and are undertaken by the Public Health Laboratory Service only by special arrangement.

COMING EVENTS

Veterinary Congress

The 14th International Veterinary Congress will be held on Aug. 8–13 at the Central Hall and Church House, Westminster. Subjects to be discussed include the control of bovine tuberculosis, *Brucella abortus* infection, and meat inspection. Information may be obtained from the National Veterinary Medical Association, 36, Gordon Square, London, W.C.1.

Air Medicine

The 20th Annual Convention of the Aero Medical Association will be held at the Hotel Statler, New York City, on Aug. 29–Sept. 1.

South African Medical Congress

The Medical Association of South Africa will hold its 37t medical congress and 16th annual scientific meeting at th University of Capetown, Rondebosch, on Sept. 19–24. Part culars may be obtained from the honorary organizing secretar 37th S.A. Medical Congress, Medical House, 35, Wale Stree Capetown.

International Society of Surgery

The thirteenth congress of the International Society Surgery will be held at New Orleans, Louisiana, U.S.A., fro Oct. 10 to 15 under the presidency of Professor G. Grey Turn (chairman of the British Executive Committee), when th following subjects will be discussed: "The Surgery and Path logy of the Pancreas, especially in Relation to its Endocrir Function," to be opened by Professor Ian Aird (London); "Th Surgery of the Parathyroid Glands," to be opened by D Paolucci (Rome); "The Surgery of the Suprarenal Glands," be opened by M. R. Fontaine (Strasbourg); "The Patholog and Surgery of the Pituitary Gland," to be opened by M. Pa Martin (Brussels); "The Treatment of Post-operative Thron bosis and its Sequelae," to be opened by Dr. A. Ochsner an Dr. de Bakey (New Orleans); "The Causes of Recurrence aft Operations on the Biliary Tract," to be opened by M. R. Dem (Vienna). Members who wish to take part in discussions a reminded that their names should be sent without delay Dr. Dejardin, Secretary-General, 141, Rue Belliard, Brussel Belgium. Members are individually responsible for makir their own travel arrangements, whether by the route outline in the official programme or otherwise.

SOCIETIES AND LECTURES

Tuesday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Stree London, W.C., July 26, 11 a.m., "*Sociological Problems in Rel tion to V.D.*," by Dr. R. Lees.

Wednesday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Stree London, W.C., July 27, 11 a.m., "*Psychological and Medico-leg Aspects of V.D.*," by Dr. W. N. Mascall.

Thursday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Stree London, W.C., July 28, 11 a.m., "*The Problem of Leucorrhoea*, by Dr. W. N. Mascall.

Friday

BIOCHEMICAL SOCIETY.—At Biochemistry Department, Universit College, Dundee, July 29, 11 a.m., 278th meeting. Papers will b read.

Saturday

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—A Leicester, July 30. Presidential address.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Essex-Lopresti.—On July 11, 1949, at Birmingham, to Muriel (née Harrop M.B., B.S., D.R.C.O.G., wife of Mr. P. Essex-Lopresti, F.R.C.S., a sist for Timothy—Catherine.

Harper.—On July 5, 1949, at Swindon, to Dr. Marita Harper (née Shattock wife of Dr Eric Harper, a daughter.

McDonagh.—On July 10, 1949, to Dr. and Mrs. McDonagh, Stanley, Pert a daughter.

MARRIAGES

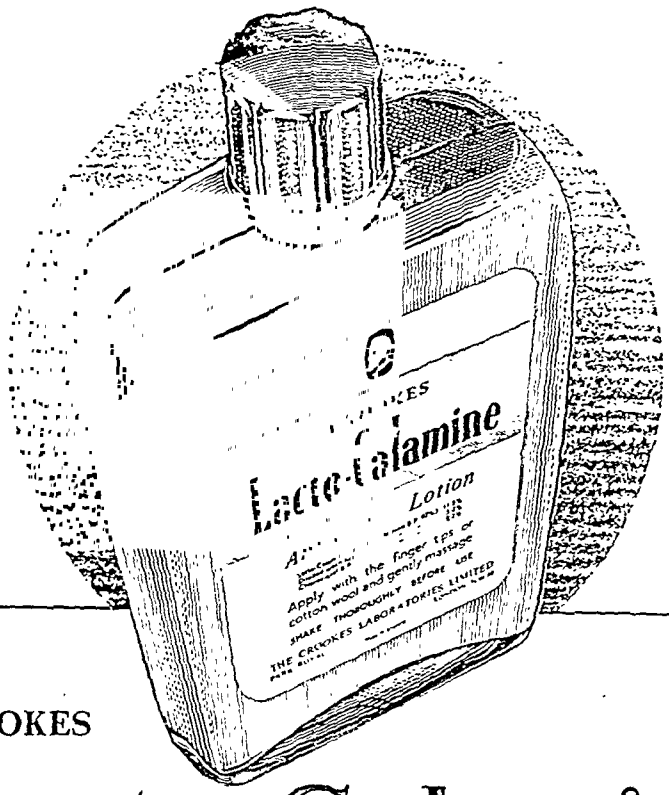
Brennan—Reed.—On June 18, 1949, at St. Marks, North Audley Stree London, W., Squadron Leader Terence N. N. Brennan, M.B., B.Ch., Mrs. Betty Reed, Cambridge, widow of the late Lieutenant E. J. Reed.

DEATHS

Brown.—On July 13, 1949, at Grosvenor Villa, Gullane, East Lothian, Robe Archibald Brown, M.B., Ch.B., Surgeon Captain R.N., retired.

Campbell.—On June 19, 1949, at Phoenix House, Sutton Oak, St. Helen Lancs, Donald Campbell, M.R.C.P., aged 66.

Carre-Smith.—On July 14, 1949, in London, Herbert Lovell Carre-Smit M.R.C.S., L.R.C.P., aged 80.



Collier.—On July 11, 1949, at Lancing, Sussex, William Arthur Collie L.R.C.P., L.R.C.S.Ed., aged 82.

Cooke.—On July 13, 1949, at 48, Kingston House, London, S.W., Sir Jam Douglas Cooke, F.R.C.S., aged 70.

Fisher.—On July 13, 1949, at Lynton, Cheltenham Road, Gloucester, Theodo Fisher, M.D., F.R.C.P., aged 86.

Gerrie.—On July 4, 1949 at Harrogate, John Gerrie, M.B., Ch.B., F.R.C.S.Ed of 2, Queen's Gardens, Aberdeen.

Gourlay.—On July 15, 1949, at Rathmore, Elgin, Frederick Gourlay, M.D., i his 82nd year.

CROOKES

Lacto-Calamine

. . . . presents high-grade colloidal calamine of exceptional covering and protective power, in a specially evolved lotion base. Thanks to its semi-emollient qualities it avoids the drying effects of ordinary calamine yet, being non-greasy, it clings without cloying to the normal surface of the skin.

IN SKIN CONDITIONS, from acne to urticaria, prescribed when a mildly stimulating yet soothing application is needed. For chapped skin, sore nipples and itching conditions in general.

For ROUTINE USE—Invaluable against sunburn, excessive sunshine and cold dry winds.

IN THE NURSERY—Against chafing and teething rashes.

PACKINGS: *Available in 4 oz. bottles and also supplied as a Cream in 1 oz. pots and Talcum Powder in sprinkler tins.*

THE CROOKES LABORATORIES LIMITED · PARK ROYAL · LONDON · N.W.10

Left Ventricular Failure ...

In manifestations of left ventricular failure the action of Cardophylin may be of great value. This action is probably two-fold, consisting of an increased blood supply to the failing myocardium as a result of coronary vasodilatation and a direct stimulating effect on respiration.

Cardophylin

(THEOPHYLLINE-ETHYLENEDIAMINE)

VASODILATOR, RESPIRATORY STIMULANT AND DIURETIC

In tablets for oral use; ampoules for intravenous and intramuscular injections, suppositories. Literature and samples on request.

Home orders and enquiries, please, to

BRITISH CHEMICALS & BIOLOGICALS LTD.
Loughborough, Leicestershire

For weight reduction ...

'DEXEDRINE' is perhaps the most effective of the therapeutic agents available for controlling appetite. It successfully inhibits the desire for food while sparing the patient the discouragement and irritability which often accompany adherence to a low-calorie diet. The use of 'Dexedrine' makes unnecessary the administration of potentially dangerous preparations such as thyroid. Eminently satisfactory weight loss can be achieved—safely and surely — when 'Dexedrine' is taken by itself.

• *Available for prescription in packs of 24 tablets.*

Sample and literature on request.

'DEXEDRINE' TABLETS

Each tablet contains 5 mg. dextro-amphetamine sulphate

MENLEY & JAMES, LTD., 123 COLDHARBOUR LANE, LONDON, S.E.5

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vitamin C in Fresh Fruit

Q.—*Is there any evidence to support the view that the vitamin-C content of fresh fruit is mainly to be found just under the peel or skin or actually in it? Is it a fact that bananas and fresh strawberries contain negligible amounts of vitamin C?*

A.—There is experimental evidence that the vitamin C of apples is found mainly in the tissues underneath the skin. The vitamin-C content diminishes fairly rapidly from the skin inwards. The amount in the cuticle is not great, but much would be removed in peeling in the ordinary way. There is little experimental evidence about the vitamin-C content of different parts of the pear, which is poor in this substance. The question would not apply to fruits like the orange, or to soft fruits which are wholly edible. The vitamin-C content of apples varies widely from about 25 mg. per 100 g. for the Bramley Seedling to about 8 mg. or less for the Worcester Pearmain. The banana has about the same amount of vitamin C as apples of the latter type. Of native fruits the strawberry is one of the richest in vitamin C, with about 60 mg. per 100 g.—that is, second only to the blackcurrant, with about 200 mg. It is, on the average, superior to the orange, with about 50 mg.

Epidermophytosis

Q.—*What is the risk of contagion from epidermophytosis between the toes? The problem arises especially in connexion with children sharing bedrooms during summer holidays. Is the risk lessened as time passes? What is the treatment, and is any form of prophylaxis possible?*

A.—It should be mentioned that the majority of patients referred to dermatologists as suffering from epidermophytosis prove to have pompholyx of constitutional origin. Confirmation of diagnosis by microscopical examination and culture is desirable. Risk of contagion is great, especially through contact in bed. It is much reduced by parasiticidal measures, the wearing of protective socks in bed and of sandals about the house and bathroom, and the use of toilet powders containing 2% salicylic and boric acids in talcum between the toes by day. Reference may be made to questions in the *Journal* of June 5, 1948, p. 1120; Jan. 22, 1949, p. 164; and Feb. 19, 1949, p. 331, concerning other prophylactic measures. Modern treatment with fatty acids and their esters, such as undecylenic, propionic, and caprylic acids, is very effective. There are many suitable preparations on the market.

Complications of Treatment of Varicose Veins

Q.—*Could you give me any statistics relating to the incidence of pulmonary embolism and other potentially fatal complications following ligation and injection treatment of varicose veins? Is it customary to keep the patient in bed for any length of time after the operation, or is the modern method to allow active exercise immediately? Also are anticoagulants needed post-operatively?*

A.—Statistics on this point are not readily obtainable, but nevertheless deep femoral thrombosis and fatal pulmonary embolus do occur and are reported at coroners' inquests. Further causes of death are anaphylaxis and suppression of urine, which may be due to the injected solution. Violent haemorrhage from the slipping of a ligature may also be directly fatal or predispose to later embolism. Ambulation immediately after operation is imperative if deep thrombosis and embolism are to be avoided. Operation and injection should not be undertaken in those whose family and personal history reveals several repeated thromboses so easily provoked as to justify the diagnosis of thrombophilia. Intervention in these patients may cause death or disablement from venous thrombosis, or may be followed by arterial involvement with loss of a limb.

Anticoagulants are essential if deep thrombosis or embolism has occurred, starting with 45,000 units of heparin and 300 mg. of dicoumarol for two days and then continuing with amounts of dicoumarol adequate to increase the prothrombin time by 120%. When the clotting is under control, ambulation can be resumed.

Bram's Test for Hyperthyroidism

Q.—*What is Bram's test for hyperthyroidism, and how is it applied?*

A.—Bram's test for hyperthyroidism depends on his observation (*Med. Rec., N.Y.*, 1920, 98, 887) that 95% of thyrotoxic patients can tolerate large doses of quinine without evidence of cinchonism. In his book *Exophthalmic Goitre and its Medical Treatment* (London, Henry Kimpton, 1936) he suggests that the patient should be given 12 capsules, each containing 10 gr. (0.65 g.) of quinine hydrobromide or sulphate. The patient is instructed to take one of these capsules three times daily, and the non-appearance of symptoms of cinchonism within four days is considered as a positive reaction. Bram obtained a negative reaction in only 4.25% of thyrotoxic patients, and he believed that tolerance of quinine and basal metabolism run parallel.

Muscae Volitantes

Q.—*Is there any general or local treatment for muscae volitantes?*

A.—Muscae volitantes are generally of a septic, haemorrhagic, or degenerative origin. In the first two instances successful treatment of the cause will prevent further increase in the muscae. The elimination of muscae is a difficult matter. Potassium iodide by mouth is sometimes useful, and the muscae are much less obvious if glasses properly correcting the focus are worn. Subconjunctival injections of hypertonic saline, etc., seem to have no effect. In traumatic cases with a haemorrhagic origin aspiration of a moderate quantity of vitreous sometimes helps (50% of cases in the writer's experience). For the type due to degeneration of the vitreous no treatment is effective.

Intestinal Haemorrhages

Q.—*Within 12 months an unmarried female aged 24 has had three severe intestinal haemorrhages, which occurred without warning. There is no history of dyspepsia, nor has she any abdominal symptoms. No abnormality has been found on x ray or proctoscopy, or at laparotomy. She has suffered from a minor degree of spondylitis for the past 10 years. Can you suggest a diagnosis and treatment?*

A.—The most likely cause of severe intestinal haemorrhage in a woman of 24 is ulceration associated with a Meckel's diverticulum, but this presumably has been excluded by laparotomy. Other possibilities include hiatus hernia of the stomach—in these cases haematemesis would be more likely than melaena—and simple tumour of the small intestine; lipoma, fibroma, and leiomyoma can all cause recurrent haemorrhage and, if small, might be missed at laparotomy. Telangiectasia of the gut, if part of the familial haemorrhagic telangiectasia (Rendu-Osler-Weber disease), is likely to be associated with epistaxis.

Further investigation of this case should include a barium meal for small-intestinal pattern and to exclude hiatus hernia; gastroscopy; examination of stools for occult blood to see whether the bleeding persists; and, should massive haemorrhage occur again, a laparotomy at the time of bleeding so that the level of haemorrhage in the gut can be ascertained. The following references may be useful: Eads, J. T., 1946, *J. Amer. med. Ass.*, 131, 891; Kennedy, H. P., 1947, *New Engl. J. Med.*, 237, 180; Allison, T. D., and Babcock, J. R., 1948, *Ann. Surg.*, 127, 754; Baker, H. L., and Halley, H., 1946, *Ann. Surg.*, 123, 1067.

Valsalva Experiment

Q.—*Can you give the physiological explanation of the after-dinner trick whereby the victim is rendered temporarily unconscious by strong compression of his chest, held fully expanded in deep inspiration, by the interlocked encircling arms of the operator? I have seen this performed only once, when the victim became unconscious for a few seconds after compression for about half a minute. He gave a slight convulsive jerk before regaining consciousness, which was immediate and full. The pulse was slow, full, and regular, and there was no after-effect or ill feeling of any sort. I have found no record of tragedy, but I feel that this procedure must be potentially dangerous.*

A.—It is possible to render a victim unconscious by strong compression of the chest aided by his natural reaction, which consists of forced expiration against a closed glottis. This is the Valsalva experiment, and if carried out sufficiently vigorously it halts the circulation, the intrathoracic pressure being so greatly raised as to prevent cardiac filling. In such circumstances loss of consciousness must be associated with absence of the pulse. The procedure is unlikely to be dangerous in healthy subjects, for the circulation is fully restored immediately the individual is released.

Delirium Tremens

Q.—*What is the best treatment for delirium tremens?*

A.—It is perhaps best to tide the patient over with small doses of alcohol and intramuscular injections of paraldehyde in doses of 2 dr. (8 g.) repeated at four-hourly intervals if necessary. Any form of adequate sedation will relieve delirium.

Persistent Abdominal Sinus

Q.—*About a year ago a classical caesarean section was carried out in a woman of 22 with contracted pelvis due to spastic hemiplegia. The uterus was emptied and sutured with silk mattress sutures. The puerperium was uneventful except for a stitch abscess in the abdomen, which resolved after treatment by fomentations. The uterus involuted satisfactorily, though there is slight menorrhagia. After three months another abscess developed in one of the abdominal sutures and a piece of catgut was extruded; this was followed by a sinus which has persisted, and through which bleeding has occurred during the last three menstrual periods. Recently one of the uterine sutures was extruded through the sinus, which still persists and remains troublesome. What is the prognosis, and what further steps do you recommend?*

A.—This patient would appear to have either a uterine fistula or an endometrioma of the abdominal wall, or both. A spontaneous cure is now unlikely, and there is little to be said for continuing conservative measures. Any operation, however, should be conservative in nature and should aim at complete excision of the scar and sinus and the restoration of normal uterine function. Preliminary studies by means of radio-opaque media injected along the sinus track, and also into the uterine cavity through the cervix, would probably be helpful. The operation is likely to be difficult and should be carried out by an experienced gynaecologist.

NOTES AND COMMENTS

Dicoumarol and Prothrombin Level.—Dr. G. A. MATTHEWS (Hemel Hempstead, Herts) writes: I was surprised to see in "Any Questions?" (July 2, p. 38) an answer mentioning the use of Russell viper venom for measuring the prothrombin time of patients on dicoumarol therapy. It has been conclusively shown[1] that Russell viper venom, when used as a thromboplastin, does not measure the prothrombin content of plasma, and that the coagulation times obtained with this thromboplastin bear no recognizable relationship to the availability of prothrombin in a patient under treatment with dicoumarol. It follows from this that to attempt to control dicoumarol therapy by means of Russell viper venom as a thromboplastin can be positively dangerous, as several workers have discovered,[2 3] though the blame is often wrongly put on the use of dicoumarol. Dicoumarol therapy is a safe procedure when brain thromboplastin is used, as in Quick's one-stage technique of measuring prothrombin times, as has been shown in my laboratory during the past two years. I trust, Sir, that you will see that steps are taken to correct the dangerous advocacy of a discredited method of controlling dicoumarol therapy.

Dr. A. F. MOHUN (London, N.19) writes: There is now sufficient evidence available to justify the statement that the use of viper venom as a source of thromboplastin is fraught with danger to the patient, in that this reagent may on occasion fail to disclose that the prothrombin time is in fact approaching, or has already reached, a dangerous prolongation. Alternative reagents have hitherto consisted of saline extracts of acetone-dried human or rabbit tissue (usually brain). These are free from what has become known as the "viper venom effect." An even simpler form of extract has been devised by Dr. M. Toohey, of New End Hospital, Hampstead (personal communication). I understand that an account of this is in the press. Finally, I should like to express my personal opinion that your reply to the question would have performed a real service to clinicians and pathologists if it had confined itself solely to the statement that the control of dicoumarol therapy is achieved by aiming at keeping the patient's prothrombin time within the range of one and a half to two and a half times the normal control time, using the same reagents. It is still not sufficiently appreciated that "prothrombin indices" and "prothrombin percentages" are calculations whose only basis is the measurement of time. No advantage is gained by elaboration of the basic data. The calculating of "prothrombin percentages" implies that prothrombin is a chemical individual, and that saline dilutions of normal plasma truly imitate plasmas from patients receiving dicoumarol: neither of these implications can be substantiated—they are therefore not only unnecessary but possibly misleading. Although the chemistry of the prothrombin time reaction is obscure, the principles of the control of dicoumarol treatment are clear and well substantiated: Use a potent thromboplastin other than viper venom; measure the prothrombin time of the patient's plasma and that of a normal control plasma (both within three to four hours of removal of the blood); regulate the dosage of dicoumarol with the aim that the time ratio shall lie between one and a half and two and a half. The method of collection of the blood and the interpretation of the results call for personal collaboration between pathologist and clinician.

Transient Giddiness.—Dr. DAVID COWAN (Johannesburg) writes: In "Any Questions?" (May 28, p. 968) a question was asked on the causes and treatment of momentary transient vertigo. A possible cause not mentioned in your answer, and one I have met with on several occasions, is that of cerumen in the ear, deep enough presumably to cause pressure on the tympanum. Syringing gives complete relief.

Corrections

The report of the meeting of the Section of Ophthalmology held on June 30, which appeared in our issue of July 9 (p. 92), incorrectly summarized Dr. Alice Carleton's views. The last sentence reporting her observations does not represent her opinion.

In the account of the combined meeting of the Sections of Obstetrics and Gynaecology and Dermatology held on June 30, which appeared in our issue of July 9 (p. 88), Dr. Elizabeth Hunt is incorrectly reported to have said that in her experience psychogenic causes of pruritus vulvae were rare. In fact she said that pruritus vulvae due solely to psychogenic causes was in her experience rare.

In the report (July 16, p. 165) of Dr. W. Pointon Dick's remarks during the discussion on tuberculosis and occupation at the meeting of the Section of Occupational Health it was stated: "In return visits it was found that the rate of new cases per 100 examined was reduced by a third." This should have read "reduced to a third."

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JULY 23 1949

THE SECRETARY REPORTS

CONSULTANTS' CONTRACTS

The Joint Committee for Consultants and Specialists has made the following announcement:

The Joint Committee of the Royal Colleges, the Royal Scottish Corporations, and the Central Consultants and Specialists Committee has now completed its examination of the "Terms and Conditions of Service of Hospital Medical and Dental Staff (England and Wales)" in the light of the observations of its constituent bodies. As reported in the medical press a fortnight ago, the Joint Committee decided on July 5 to reopen discussions with the Ministry on three points—conciliation machinery and arbitration, facilities for private treatment in hospitals, and the remuneration of part-time clinical teachers.

After receiving the reply of the Ministry, the Joint Committee met representatives of the Ministry on July 18, when the following assurances were received:

1. Arbitration

The Ministry has agreed

(*a*) That no changes will be made in the terms and conditions of service without discussion in the appropriate part of the Whitley machinery, when established, and this will be established as soon as possible.

(*b*) That remuneration is a subject which is suitable for arbitration.

(*c*) That save in exceptional circumstances, and after the conciliation machinery of Whitley has been exhausted, issues of remuneration remaining in dispute will go either to arbitration or for inquiry and report by a committee.

(*d*) That the words "by the Minister of Health" will be deleted from the opening paragraph of the model contract, so that it would simply refer to the terms and conditions of service "determined from time to time."

2. Private Practice

The Ministry reiterated its previous assurances that it was not its intention to place difficulties in the way of private practice. It has agreed that patients admitted to private hospital beds under Section 5 of the Act will pay fees for professional attendance to part-time practitioners in addition to the maintenance charges, except where the patient is occupying accommodation under the proviso to section 5 (1)—i.e., on medical grounds.

The Ministry has agreed that individual practitioners are free to leave untouched or to delete from the whole-time contract any of the clauses which are enclosed in square brackets, including Clause 5 requiring attendance on patients occupying beds under Section 5 of the Act who have not made private arrangements under Section 5 (2).

3. Clinical Teachers

Assurances, shortly to be made public, have been received on the arrangements for the remuneration of clinical teachers.

The Joint Committee decided, with the assent of the Ministry, to continue negotiations on a number of outstanding points. It feels that it is now able to advise hospital staffs to enter into permanent contracts.

A word or two on the background. The Government accepted the Specialist Spens report. The Ministry of Health proceeded to translate the Spens recommendations into a detailed scheme of terms and conditions of service. The Ministry's first thoughts were expressed in a document which was submitted to the Joint Committee, in confidence, for its observations. The Joint Committee, after consulting its constituent bodies, put forward a number of criticisms and suggestions. A number of these were accepted by the Ministry.

The next phase was the submission by the Ministry to the Joint Committee of its second thoughts in the form of concrete proposals. The Joint Committee, having gathered up criticisms and comments from its constituent bodies, proceeded to discuss the proposals with the Ministry and to press for certain changes, some of which were made. The last phase was the issue by the Ministry of a revised document with an explanatory memorandum. The question now before the Joint Committee was what advice it should offer to consultants and specialists generally on the issue of the signing of contracts.

When the Joint Committee met on July 5 it had before it the comments of its constituent bodies on this point. It decided that it could not proceed to advise consultants to sign permanent contracts until further and satisfactory discussions had taken place with the Ministry on three points—conciliation and arbitration machinery, facilities for private practice, and the remuneration of part-time teachers.

The final meeting of the Joint Committee with the Ministry took place on Monday last, and the outcome of it is fully set out in the announcement of the Joint Committee with which this report opens.

Arbitration

The issue of arbitration has loomed large in recent discussions. Behind the profession's attitude has been a determination to avoid the position in which, disagreement having been reached between the Minister and the profession on the subject of remuneration, there was no escape from the Ministerial *ipse dixit* as to what the remuneration should be. There were doubts as to whether remuneration was in fact regarded by the Government as susceptible to arbitration. It has now been agreed by the Ministry that remuneration is an issue open to or suitable for arbitration. Subject to the words "save in exceptional circumstances" it is agreed that whenever the normal conciliation machinery has failed to provide agreement on an issue of remuneration the question should be referred to some external body for arbitration or inquiry. It may be agreed that it should go for settlement by arbitration, or it may go for special inquiry and report by a committee, the findings of which would be available to but not binding on the parties. While it is true that the Minister is not bound to accept the advice of a committee not empowered to arbitrate, it is equally true that the profession is not so bound either. Further, such a report has a moral force which neither side will find it easy to escape.

A good deal hangs on the meaning of the words "save in exceptional circumstances." It is understood that an example of such special circumstances is an economic crisis in which national considerations override all others.

Private Practice

The Joint Committee has pressed again and again that nothing should be done unfairly or unnecessarily to restrict the facilities for private practice. This is a question not so much of the

details of an Act or the items in the terms and conditions of service, but as to the spirit in which the service is administered. On two points the position has now become quite clear. The first is that when a patient enters a private ward, whether or no previous arrangements have been made for treatment, that patient assumes an obligation to pay for both accommodation and professional services except where the admission has been in effect that of a public patient entering private accommodation on clinical grounds. The Ministry accepted this interpretation of the position, which is more than can be said for some hospital management committees. Secondly, it was made clear that the individual consultant or specialist offered a contract is free to accept or not to accept the words enclosed in square brackets. A particular significance of this is that the whole-time officer is not to be required to agree to treat patients in private wards, although there will be circumstances in which, because there is no part-time officer to undertake the work, it is desirable that some special arrangement is reached with the whole-time officer.

Future Negotiations

The Joint Committee made clear to the Ministry—and the Ministry assented—that the detailed scrutiny of the terms and conditions of service and of the various features of the Service must continue, and representations will continue to be made on a number of outstanding points. Among them is the position of some medical superintendents. An important concession has been made by the Ministry in the mental hospital field to the effect that for practical purposes the mental hospital superintendent will be regarded as mainly engaged in clinical work and remunerated according to his clinical standing, without reduction because of time spent on administrative work. But the position of the medical superintendent engaged wholly or predominantly on administrative work remains unsatisfactory. Among other points which remain to be considered are the definition of the field to which the appointment of S.H.M.O. will in future be limited, the establishment of a central appeal machinery for grading, problems of registrars—including their grading, the application of the Spens standards to medical officers of regional hospital boards, mileage, subsistence allowances, and study leave. The Joint Committee will continue with this work.

MEDICAL SUPERINTENDENTS IN THE N.H.S.

THE SCOTTISH VIEW

Considerable opposition has been aroused among medical superintendents in England and Wales to the terms and conditions of service offered them by the Ministry of Health. The terms take no account of the fact that a medical superintendent has a medical qualification, since for the work of administration he is offered the same pay as a lay administrative officer would receive—with the small exception that his remuneration is not affected if he gives only a small proportion of his time to administrative duties. This scheme has been interpreted as an attempt by the Ministry to discourage medical men from undertaking administrative work, and contested on the grounds that it is wrong to pursue a policy such as this through the method of remuneration.

The medical superintendent has always played an important part in hospital administration in Scotland, and the profession there does not accept the view that he is an anachronism in the modern hospital. The Scottish Negotiating Committee (now dissolved) informed the Department of Health of its views, the substance of which is contained in a memorandum prepared by a special subcommittee and unanimously approved by the Central Consultants and Specialists Committee (Scotland).

The Department has invited the Scottish Joint Committee for Consultants and Specialists (whose composition is recorded at p. 55) to discuss what should be the appropriate salary scales for medical superintendents. The Department will now draft proposals which will be the basis of negotiation with the Scottish Joint Committee.

Two Systems of Administration

In discussing the problem in its memorandum the special subcommittee finds that two systems have evolved. They are sometimes referred to as the parallel and the hierarchical. In the parallel system the management body has a lay executive functionary and obtains its technical advice from a medical committee. In the hierarchical system the executive functionary is a medical man, and therefore qualified also as a technical adviser. In practice the two systems are not absolutely distinct, but they do in general represent two different concepts of managerial structure.

In Scotland the larger voluntary hospitals, with few exceptions, use the hierarchical system. A medically qualified man superintends the day-to-day running of the institution on behalf of the managing body. Through apprenticeship in the local authority service, or in other ways, he has added administrative experience to his basic medical training. Advocates of the parallel system argue that years of medical education are wasted when a doctor is appointed to an administrative post. The subcommittee cannot accept this argument, and suggests that its appeal probably derives from the complexity of the large modern hospital, which has tended to obscure its primary purpose to provide treatment for the sick.

It has been argued that suitable training in hospital administration can provide the necessary medical understanding for running a hospital, but the subcommittee finds this difficult to believe, since most of the important problems of hospital administration are essentially medical. Purely medical problems often arise which require decisions that only a medical man can properly make. Examples are decisions about the admission and discharge of patients, the distribution of patients between different parts of the hospital, and decisions on competing claims on medical matters from members of the hospital staff. This consideration applies both to physician superintendents and to purely administrative medical superintendents, and "it appears to us to be incontrovertible that such day-to-day decisions would require the authority of the executive head of the hospital."

The Lay Secretary

The subcommittee concedes the necessity of a lay secretary, suitably trained in administration, who would look after the book-keeping, accountancy, stores, and similar aspects of non-medical management, but such services should always be ancillary to the main purpose of institutions designed for treating sick people. The medical superintendent ought to be the chief executive officer of the hospital or group of hospitals, states the subcommittee. "We are satisfied that the balance of argument is strongly in favour of the continuance of the traditional Scottish system, and are convinced that to develop and encourage it is the policy of choice."

If men are to come forward as medical superintendents two conditions must be satisfied: first, the salary scale must be satisfactory and materially in excess of that applicable to lay secretaries; secondly, opportunity for training must be provided. The second provision would require the creation, where necessary, of appointments as deputy medical superintendents, and medical schools would have to start courses of training in medical administration. The subcommittee points out that Professor J. M. Mackintosh, Dean of the London School of Hygiene and Tropical Medicine, has for some time advocated the starting of such courses.

The Specialist Superintendent

The subcommittee finds it difficult to imagine how a special hospital, such as a tuberculosis sanatorium, an orthopaedic hospital, an infectious diseases hospital, or a mental hospital, can be run efficiently if the chief clinical specialist is not also the administrative and executive head. A lay secretary is still necessary in such hospitals, but his status should be inferior to that of the specialist superintendent, since the non-medical aspects of management are subsidiary and contributory to the treatment of the patients. If the duties of the specialist

superintendent, which are intimately related to the care and welfare of the patients, were made the responsibility of a lay secretary, he could carry them out only by continual reference to a member of the medical staff, who would in fact carry the responsibility and have his time occupied in the execution of these duties.

The subcommittee concludes that if the superior status of the specialist superintendent is to be ensured two conditions must be fulfilled: (1) The component of his salary in respect of his administrative duties must be at a substantially higher rate than that for secretaries; (2) the total salary of the specialist superintendent, who would usually work full-time and for much longer hours than his specialist colleagues scheduled for so many sessions per week, and be resident in the hospital, must not be lower than that of his specialist colleagues.

Government's Objective Wrong

Finally, the subcommittee comments on the Government's policy in the following words: "In the Government's proposed terms and conditions of service for hospital medical staff it is stated that the objective will be to reduce to a minimum the time to be given by medical staff to administrative duties. It is our opinion that, the number of doctors concerned in medical administration being small, no important benefit would accrue to the clinical side of the National Health Service if the numbers employed as medical superintendents declined, and that *per contra* the retention of the medical superintendent as the executive head of the hospital would bring to the Service greater advantages in efficient and smooth administration. Holding this opinion, we consider that the Government's objective, as stated, is not the right one. In any case we believe it to be both wrong in principle and unwise in practice to determine in this oblique fashion what should be determined directly and on merit—namely, the future of the medical superintendent."

HEALTH CENTRES

DISCUSSION AT ROYAL SANITARY INSTITUTE

"In principle the vast majority of doctors seem to favour work in a health centre. In practice they are concerned with several very real difficulties, some of which can only be satisfied by Government action." With these words Dr. J. A. Scott, Deputy M.O.H., London County Council, prefaced his discussion of general practitioners' problems in relation to health centres when he spoke at the Royal Sanitary Institute on July 13. The Minister had said that private practice could not be carried on in a health centre. That provoked the rejoinder that health centre practice should be rent free or the practitioner would still be under the obligation and expense of maintaining his private premises for a very small number of private cases. Most doctors went further and said that on those terms they would not join in health centre work. An example of private practice was the life insurance examination. Why should they not take place in health centres? The ancillary staff of a health centre was not paid to assist doctors in their private work, but it was difficult to see private work becoming substantial. He hoped that second thoughts would prevail at the Ministry.

Protection Against "Squatting"

The next question doctors asked, he said, was, "What kind of guarantee can you give me that a newcomer will not be allowed to 'squat' in the premises I vacate?" It was not unnatural that a doctor should remember the numbers of patients who had joined his list because they lived near him. Protection for a year or two by declaring the area closed to new medical entrants was requested, and the claim, whatever the difficulties in meeting it, was bound to evoke sympathy.

Consultant Sessions?

General practitioners with whom he had discussed the question of consultant facilities at the health centre did not attach much importance to them. Their views seemed to be that the modern specialist required a good deal of technical equipment, and even if he came to the health centre he would have to refer most of the cases back to himself at the hospital for further investigation. That was a tenable view, but it disappointed him. The general practitioner as a rule had no regular personal contact with the big general hospitals, and regular consultant sessions at the health centre seemed to offer a useful meeting-ground at which the benefits would be mutual.

Adaptation of Buildings

Mr. W. J. Durnford, Senior Architect to the London County Council, described the L.C.C. health centre at Woodberry Down and then discussed the adaptation of existing buildings to health centres. Large domestic buildings in good structural repair could be adapted quite successfully, but he doubted whether many suitable buildings existed. Experience proved that major adaptation absorbed much skilled labour, that production was slow and costly, and that the results were seldom satisfactory.

Facilities Available

Dr. A. Talbot Rogers, chairman of the B.M.A. Committee on Health Centres, said that the average urban centre should accommodate up to six doctors, each practitioner having his own waiting-, consulting-, and examination-rooms. Maternity and child-welfare and school medical services should be developed in co-operation with the general medical and dental services.

Consultation with specialists should normally be at hospital, where pathological and radiological services would be provided. Apart from a room for simple pathological tests and possibly provision for dental radiology, no arrangements for those diagnostic services needed to be made at the health centre. A dispensing service could be of great value and should be installed experimentally in some centres.

He agreed that to enable doctors to make the transition to health centre practice with the least risk and reluctance everything possible should be done to give them the help and assurances they required, even if that meant the right to attend some of their few remaining private patients at the centre, or protection against the occupation of vacated premises by a rival practitioner.

SCOTTISH JOINT COMMITTEE FOR CONSULTANTS AND SPECIALISTS

In agreement with the Central Joint Committee for Consultants and Specialists a Scottish Joint Committee has been set up to discuss with the Department of Health for Scotland matters specifically affecting the hospital services under the National Health Service (Scotland) Act. The committee is composed as follows:

Central Consultants and Specialists Committee (Scotland).—Mr. W. S. Mack, Dr. T. Murray Newton, Mr. I. Simson Hall, Dr. J. H. Wright.

Royal College of Obstetricians and Gynaecologists.—Mr. J. Hewitt.

Royal Faculty of Physicians and Surgeons of Glasgow.—Mr. A. B. Kerr, Dr. W. R. Snodgrass.

Royal College of Surgeons of Edinburgh.—Sir Henry Wade, Mr. F. E. Jardine.

Royal College of Physicians of Edinburgh.—Dr. J. D. S. Cameron, Dr. I. G. W. Hill.

Secretary.—Dr. E. R. C. Walker.

NATIONAL FORMULARY

The Ministry of Health states that assistants working with doctors in the National Health Service, even if the assistants themselves are not on the executive council's list, should be provided with copies of the *National Formulary*.

HOSPITAL SUPPLIES

CENTRAL PURCHASE

X-ray apparatus, films, and paper, laboratory equipment, streptomycin, orthopaedic appliances, and some other articles are already purchased for hospitals by the Ministry of Health. The Minister has now decided in the interests of economy and efficiency that central purchasing shall be extended and carried out wherever necessary. The Supplies Division will notify boards of governors and hospital management committees of the types of equipment and stores to be purchased in this way, and the Ministry invites these bodies to suggest particular classes of goods to be considered for early action.

RESEARCH AND MILITARY SERVICE

At a recent meeting the Committee of Reference passed a resolution reaffirming its opinion that a practitioner with a liability under the National Service Acts shall be discouraged from embarking on long, elaborate, or expensive research work, particularly if it will not enhance his particular value to the Forces. The resolution was sent to the Central Medical War Committee.

The Committee of Reference is under the aegis of the Minister of Health, and makes recommendations to him on the call-up of specialists in the London area for National Service, and also on their specialist grade in the Services. Of its 10 members, who are all medical men, four are nominated by the Royal College of Physicians, four by the Royal College of Surgeons, one by the Royal College of Obstetricians and Gynaecologists, and one by the London County Council.

POSTGRADUATE COURSES FOR G.P.s

The Edinburgh Postgraduate Board for Medicine is holding a fortnight's general refresher course which starts on Sept. 12. The course is intended primarily for demobilized medical officers (Class 2) and for general practitioners. Lecture-demonstrations will be given on a wide range of subjects, particularly on recent advances in treatment, and there will be clinical demonstrations and ward visits. The fee for those not claiming expenses from Government sources is 10 guineas. Applicants should write to the Director of Postgraduate Studies, Surgeons' Hall, Edinburgh, 8, those other than general practitioners giving particulars of their qualifications and post-graduate experience.

FILM COMMITTEE

Two silent colour films—"Caesarean Section," by Dr. K. V. Bailey, Manchester University, and "Congenital Abnormalities of the Urinary Tract," by Mr. T. L. Chapman, Glasgow—were shown at a meeting of the Film Committee in the Hastings Hall on June 17, with Dr. R. P. Liston in the chair. The committee decided to include both films in the B.M.A. Film Library, and a sound commentary is to be added to Dr. Bailey's film. A film for students—"Acute Inflammation," by Dr. P. Hansell, Westminster Hospital—was also shown.

COMPLIMENTARY DINNER

The Sheffield Division of the Association gave a complimentary dinner on April 14 to Dr. W. E. Dornan, who is chairman of the Medical Practices Committee. A large party entertained him, and the chairman, Dr. R. C. Burton, paid tribute to his excellent work as a Representative for several years, as a member of Council, and as a member of the Negotiating Committee. He expressed the thanks of his colleagues and the Division for Dr. Dornan's valuable services to the profession. Dr. Dornan acknowledged the help given him so generously, and was appreciative of the honour afforded him of being able to serve the profession.

It is hoped in future to arrange an annual dinner to which wives will be invited.

DENTISTS SAY NO

The British Dental Association has advised (*British Dental Journal Supplement*, July 15, p. 11) its members to refuse to sign any permanent contract in the Hospital Service at present. Members can accept renewal of their existing temporary contracts, but in doing so should make it clear that this is without prejudice to any permanent contract.

A letter from the association to the Ministry says that discussions must be reopened with the Ministry on various subjects. These include: "That the present differentiation between the remuneration of general medical practitioners and general dental practitioners employed in hospitals is completely unacceptable to the dental profession," and "That specific provision is essential to ensure that facilities for private treatment in hospital shall be maintained and developed throughout the country for those who desire it."

HEARD AT HEADQUARTERS

The Microphone Nuisance

Now that the congress season is upon us, can nothing be done to abate the nuisance of the microphone and amplifier? For three days at the recent Congress of Obstetrics and Gynaecology at Friends House every speaker was accompanied by an amplifier on a huge pedestal which he trundled about with him on the platform when he went to the lantern screen to expound his pictures or came to the footlights to put a point directly to his audience, and the microphone had to be readjusted in height for each successive speaker. Almost every speaker spoke into it as if it were a telephone receiver, and many clung to it as if they were shipwrecked and it was a raft. The result was a constant falsification and degradation of the voice, especially for those in the front of the auditorium, who lost a great deal of what was said. Yet in Friends House, or in the Westminster Central Hall, or even in the Great Hall at B.M.A. House, any speaker, by raising his voice a little, could make himself comfortably heard without this contrivance at all. It is said that the motor-car is depriving man of the use of his legs; the microphone and amplifier will soon be depriving him of audible and intelligible speech.

A Doctor's Bill in 1809

Turning over the pages of the *Gentleman's Magazine* for 1809 we came across a complaint against an apothecary—the predecessor of the general practitioner—on the ground that he had sent in a bill for £59 for attending a man and his wife for one year, the wife having had very little illness. This complaint was followed in the next issue by a voluminous and enthusiastic defence of the apothecary and of the profession in general. Was it fair, asked the writer, to say that an apothecary had charged £59 for a year's attendance on a married couple without relating the circumstances, the social position of the patients, the number of attendances, the nature of the illnesses, medical or surgical, and the distance—mileage in short—between the addresses? The writer went on to claim that the apothecary's was the most noble and disinterested profession in the country—witness their attendance at parish workhouses, where their scanty pittance often did not pay their expenses. And in further proof he cited their zeal in promoting vaccination, for "the success of vaccination has taken more from the pockets of apothecaries than the taxes incurred by fifty years of war."

The Status of Midwife

After all, in spite of Shakespeare, there is a great deal in a name. The term "maternity nurse" for a midwife workin with a doctor has led to misapprehension and some amount o feeling, and the Association in its comments on the report o the Working Party on Midwives recommends to the Centra Midwives Board that the use of the term shall be dropped. I urges that it should be appreciated that the midwife and th doctor are working together, and that this in no way relegate

the midwife to an inferior status. She is still a midwife and is working as such, and at any time may be called upon to act as such. That there is a confusion of ideas on this point was shown by the reception of Mr. Bevan's remarks at the recent meeting of the midwives. The two professions are not in competition.

Questions Answered

Pay in R.A.M.C.

Q.—*What is the pay of (1) a lieutenant, (2) a captain in the R.A.M.C.? What marriage allowance does he receive (a) if under 25 years, (b) if over 25 years? The rates of pay I want to know are those for a "conscript" officer doing his eighteen months—not a regular.*

A.—The rates of basic pay of lieutenants and captains, R.A.M.C. (both for National Service officers and others), are as follows:

Rank	*Daily Rate* £ s. d.
Lieutenant	1 2 0
Captain	1 8 0
Captain after 2 years as such	1 11 0
Captain after 4 years as such	1 14 0
Captain after 6 years as such	1 17 0

Specialists in the R.A.M.C. receive 4s. a day in addition.

Married National Service officers under the age of 25 years receive marriage allowance at 45s. a week; married National Service officers aged 25 and over receive marriage allowance at 12s. 6d. a day.

The rates of basic pay and marriage allowances are the same for corresponding ranks in all three Services.

Regular and short-service officers receive the same rates of basic pay as the above, but are entitled to larger marriage allowances: 3s. a day more if living in quarters, and 6s. a day more otherwise.

Holidays for Assistants

Q.—*In these modern days all workers get a stated number of holidays in the year, and it is compulsory for the employers to give these free days. I should like to know if the position is otherwise when the employer is a doctor and the employee an assistant doctor.*

A.—There is no statutory holiday period for an assistant. Holiday arrangements are normally made by mutual agreement between the principal and assistant, and in some cases the position may be covered in the assistantship agreement.

Fees for Dental Anaesthetics

Q.—*I had been giving dental gases for a dentist who is in the national scheme. When the dentists' earnings over £4,800 per annum were halved, however, on the next occasion when I gave gases he gave me a cheque for one-half of the fee's value for anaesthetics as laid down in the handbook. Is his action in keeping half the fees legal and ethical? When asked to give gases for a dentist who has his own machine and provides the cylinders of gas for it, am I now liable for payment for the gas used?*

A.—The fees for dental anaesthetics are laid down in the General Dental Services Fees Regulations, 1948, S.I. No. 1297, and are as follows:

Administration of general anaesthetic—fee per visit in connexion with the extraction of:

1–3 teeth	10s. 0d.
4–11 ,,	£1 0s. 0d.
12–19 ,,	£1 10s. 6d.
20 teeth or over	£2 0s. 0d.

It is for the dentist to claim the fee from the executive council and pass it on to the general practitioner who administers the anaesthetic.

Representatives of the dental profession claim that they should be entitled to withhold a proportion of the fee to offset expenses incurred in the provision of anaesthetic apparatus and gas, etc., and discussions are now in progress on this particular point. Normally the dentist and the doctor mutually arrange whether or not such a deduction shall be made, and definite arrangements are entered into before the extractions take place.

There is no official authority for the anaesthetic fee to be halved on account of the recent cut in the remuneration of dentists.

Sight Tests

Q.—*Several young men wearing perfectly suitable glasses have recently demanded a "sight test" for no other reason than their having been told that they should be tested every two years. This idea seems to be promulgated by certain opticians. Under the new scheme are they in order in actively encouraging by post-card reminders, etc., these repeated tests?*

A.—Except where a person is unable, or unwilling on conscientious grounds, to do so, he may obtain a sight test for *the first time* through the Supplementary Ophthalmic Service only upon a recommendation from a general practitioner. Thereafter he is entitled to go direct to an ophthalmic medical practitioner or ophthalmic optician for a further sight test at any time.

Apart from the display of a notice at his premises it is an infringement of the regulations for an optician to advertise either directly or by implication that his name is included in the list of an Ophthalmic Services Committee or that he provides or is authorized to provide services under the Act

Obstetric Emergency

Q.—*I have sent patients to hospital after attending them at delivery—e.g., for removal of retained placenta. As I am not on the staff of the local hospital I do not attend them during the puerperium, although I perform a post-natal examination at about six weeks after delivery, including pelvic examination. In such cases the local authority has refused me payment for attendance at the confinement on the grounds that the confinement was not completed by me and that I did not attend the patient during the puerperium. Is the authority correct in its interpretation of the regulations for Northern Ireland?*

A.—A similar inquiry was put to the Ministry of Health some months ago, and executive councils were informed that the full fee should be paid where a general practitioner is attending the patient and himself decides after labour has started that the patient ought to be removed to hospital on account of an obstetric emergency. There is no reason to suppose that the same ruling would not apply in Northern Ireland.

Wife Employed by Partnership

Q.—*(a) If I pay my wife for help in the conduct of my practice, must I stamp a card for her? (b) What is the maximum amount I can pay her without income-tax deductions under P.A.Y.E.?*

A.—(*a*) A doctor working single-handed who employs his wife in the conduct of his practice is not required to stamp a card for her under the National Insurance Act. If she is employed by a partnership, her husband being one of the partners, she is an employed person, for whom contributions must be made. (*b*) The maximum amount payable without P.A.Y.E. deductions is £3 a week.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Correspondence

Venereology as a Specialty

SIR,—Liverpool has a population of 795,900. Being a seaport, the unnumbered multitude of seafaring men who visit the city each year would justify one in estimating the population at at least one million. Most large industrial cities have a high incidence of venereal disease which is endemic, but a port is a nodal point on which a constant influx of V.D. converges and from which V.D. is disseminated both inland and overseas. It is not surprising, then, that the V.D. treatment centres in Liverpool deal with very large numbers of patients annually. The number of fresh attendances at the Seamen's Dispensary alone in 1947 and 1948 was over 5,000 each year, both venereal and non-venereal. Over 60,000 fresh cases have been seen at this clinic since 1931.

The diagnosis and treatment of V.D. in Liverpool is undertaken by a consultant venereologist who is director of the clinics concerned, is adviser to the Liverpool Regional Hospital Board, and is employed on a part-time basis; by three whole-time venereologists (one female and two male); and by half a dozen part-time venereologists.

Your readers will be surprised to learn that the professional assessment committee of the regional board has seen fit to accord the status of full consultant to one of this team only. All three whole-timers are to be offered contracts as senior hospital medical officers. Their years of experience in V.D. are 27 (6 in Liverpool), 15 (14 in Liverpool), and 11 (2 in Liverpool) respectively. Birkenhead, with a population of 134,160, has one whole-time venereologist of 11 years' standing. He too is to be S.H.M.O.

It might be assumed that the professional assessment committee considers the standard of venereology on Merseyside to be too low to warrant any recommendations other than those already made. This view would be refuted by all with an intimate knowledge of the clinics concerned.

To account for the downgrading of venereologists on Merseyside and possibly elsewhere there springs more readily to mind an idea which would cause such men as John Hunter, Ricord, Fournier, Jonathan Hutchinson, Ehrlich, Neisser, and a great many more who devoted much of their lives to the study of syphilis and gonorrhoea to turn in their graves. It is that venereology should not be regarded as a specialty in its own right.

There would appear to be a prevalent notion that the immediate and only sequel to the diagnosis of syphilis or gonorrhoea in whatever stage is the prescription of large doses of penicillin; that most of the venereologist's work is that of a technician applying this technique in routine fashion; and that any tyro can manage a clinic for the care of such patients who are not prepared to be fleeced for the sake of absolute secrecy. Such a conception is commonplace in the minds of medical men who overlook the fact that it was more than the convenience of patients which prompted the Government to set up special clinics for the treatment of these special diseases in 1917. These clinics were inaugurated on account of the completely unsatisfactory treatment undertaken privately by too many practitioners whose chief interest lay elsewhere. By law these clinics have to be run by special doctors, though it is readily admitted by venereologists that the standard required is quite inadequate for the designation of specialist. Also overlooked is the fact that in spite of routine work the venereologist as such is an integral part of medicine in that he is needed to rectify, where possible, the ravages of V.D. in patients who have previously been maltreated by "penicillin punchers" who, with fatuous optimism, see no further than the visible lesion.

One may be forgiven, while beset with professional scorn, for suggesting that much of a dermatologist's work is the routine diagnosis and treatment of scabies; that the anaesthetist can leave many cases to inexperienced house-men; that the obstetrician depends for his livelihood upon the successful supervision of a normal physiological function; that most of the psychiatrist's patients leave his consulting-room with the label "chronic unspecified anxiety state"; and that the radiologist's interpretation of a photograph is often less hazardous than the venereologist's interpretation of conflicting and doubtful serological tests. Indeed, every specialist performs much routine. It is the unusual and difficult which justifies his existence.

So it is with the venereologist. It is not the diagnosis of gonorrhoea and the prescription of penicillin to which he devotes his study, nor the recognition of a primary chancre and the discovery of the *Spirochaeta pallida*. It is rather the management of all forms of metastatic gonorrhoea and late syphilis. It is not knowing when and with what to start treatment, but when to stop and when to continue. It is knowing how to advise on the safety of marriage and how to avert disruption of marriage, for no other diseases have such dire repercussions on family life. It is the intelligent interpretation of serological tests and cerebrospinal-fluid findings and the recognition and treatment of drug sensitivity and intolerance. It is an appreciation of the epidemiology and social implications of V.D. The venereologist is one who not only plays a large part in preventive medicine by the proper use of drugs and by the organization of intensive follow-up of defaulters and contacts in co-operation with the invaluable services of welfare workers, he is also one whose specialty encroaches on the domain of all the other specialties. He seemingly has to trespass, and herein lies much of his trouble.

General physicians, cardiologists, neurologists, surgeons, obstetricians and gynaecologists, paediatricians, ophthalmologists, oto-rhino-laryngologists, and psychiatrists—all see the venereologist as one who might interfere. Yet none has not benefited from the teaching of venereologists and none has been unable to say of a patient, "A pity he was not in the hands of a competent venereologist many years ago."

If all other regional boards adopt the same attitude as the Liverpool Board it means that the only goal for a venereologist is to be an adviser to a board, of which there are but 14 in England. Had the object of its decision been to guarantee a constant supply of cardiovascular and neurosyphilis cases, etc., for the teaching of disease manifestations which might reasonably be made to become medical curiosities, it could not have chosen a better method than one which will ensure that none but the mentally backward take up venereology. Fair prospects would be too remote.

Is it not as rational to make a special study of the spirochaete, which can invade any tissue of the human body, as to make a special study of some region of human anatomy which can be invaded by many organisms other than the spirochaete? Moreover, is not venereology a vocation which many medical men would not follow even if tempted with a merit award in lieu of danger money?

One can only look westward with envy to the U.S.A., where venereologists receive their just acclaim and the Government, realizing the effect of V.D. on the national economy in peace as well as in war, votes $1,000,000 annually to its research.

The Lock Hospital appears to be like a ship in the process of being torpedoed. Are the captains to take to the lifeboats and the crew to go down with her?—I am, etc.,

ARTHUR S. WIGFIELD.

Liverpool.

Public Health Service Appointments

SIR,—The executive committee of the Medical Women's Federation seeks this opportunity to express its support of the action of the British Medical Association in imposing a ban on posts in the Public Health Service which are being advertised in the lay press at lower salary rates than the B.M.A. recommendations for permanent scales of remuneration for medical officers in the Public Health Service, the ban to be in force until such time as local authorities are prepared to begin negotiations on salary scales.

The struggle for equal pay for medical men and women in the Public Health Service was a long one, and the Federation would like once more to acknowledge the loyal support of the British Medical Association at that time. In the long run the battle was won largely because, with very few exceptions, medical women refused to apply for the posts blacklisted because of the lower salary offered to women, and in this way they

strengthened the hands of the negotiators. This was at a time of considerable unemployment in the profession, when to refrain from accepting an underpaid post was frequently a serious financial sacrifice.

As regards the present issue, there is often temptation for an applicant to argue the needs of his or her particular circumstances which they feel make a claim for sympathetic understanding. To such applicants we would like to say that they are both jeopardizing the issue for the profession as a whole and are in danger of placing themselves in an unhappy position and an inferior status with their colleagues both inside the Public Health Service and outside it. The Federation begs any such would-be applicants, no matter what the circumstances may be, to try to see the matter in all its bearings. We suggest that this wider professional approach to their individual problem will lead them to add their support to that of colleagues who are loyally observing the ban—and thus hasten the day when negotiations will be begun.

Should any medical woman still not be clear as to why it has been necessary to impose this ban, she is urged to write to the British Medical Association or to the Medical Women's Federation.—I am, etc.,

GERTRUDE HERZFELD,
President,
Medical Women's Federation.

Tavistock House North,
Tavistock Square, London, W.C.1.

Grading of Hospital Staff

SIR,—I am instructed by the general meeting of the Liverpool Regional Hospitals Medical Association held on July 11 to send you the following resolution:

"This meeting regrets that, in spite of cases of up-grading, there are many anomalies still existing both with regard to groups and to individuals. We are particularly concerned about the two specialties venereology and tuberculosis, in which the grading has been almost uniformly that of senior hospital medical officer. We feel that low grading will inevitably have a depressing effect on efficiency in the future, since recruitment will fall in quality.

"Some of the individual grading seems to us so unjust that we feel that it is essential that fresh consideration to individual appeals should be given forthwith.

"We therefore heartily support the British Medical Association's claim for the setting up of regional appeal committees before which the appellant will have the right to appear in person and be represented."

—I am, etc.,

V. COTTON CORNWALL,
Hon. Secretary,
Liverpool Regional Hospitals Medical Association.

Inducement Payments

SIR,—Like a good many other doctors with small rural practices in Scotland I have had my application for an inducement payment turned down by the Secretary of State for Scotland. I have reason to believe that my application was favourably recommended by the local medical committee and by the executive council in this area.

I think that it is worth bringing this matter to your notice. The way the economy axe has struck first at the smaller practices with the smaller incomes is surely an indication to the whole profession of what the official attitude is likely to be towards a general financial betterment.—I am, etc.,

D. N. B. MORRISON.

Braemar, Aberdeenshire.

School Medical Officers

SIR,—It is with alarm that one reads the report of the Annual Representative Meeting (*Supplement*, July 2, p. 12) dealing with the position of school medical officers.

The tone of such remarks of the supporters of the motion as, "The local health departments . . . seemed determined to establish themselves by all possible means," and later, "The ever-growing number of people examining other people's children . . . all patients *belonging* to other doctors," bodes ill for the development of the co-operation which one had rightly hoped to see resulting from recent enactments, and which will be essential for the progress of our medical services in the future. The motion means that the G.P is assuming the form of "veto" over the actions of his colleague in the school medical service in some cases.

Let us foster co-operation; let the traffic of information pass freely in such directions as are necessary for the working of our medical team; and let us not forget that the well-being of the patient is of greater importance than our own prestige and pseudo-ethics.—I am, etc.,

H. GRAY.

Baildon, Yorks.

The Association War Memorial

SIR,—From the report on the debate at the A.R.M. (*Supplement*, July 2, p. 26) some points of general interest have been omitted. Dr. Dain, in moving the report, told the meeting that 879 members (105 civilians) had been killed by enemy action. I, speaking in support of the Harrow amendment, asked Dr. Dain if it were known how many dependants there were of those killed, and he replied that the number was not known. Later Dr. Dain said that the Medical War Relief Fund still had £19,000 and that there were no applicants.

These facts were not generally known, either by representatives or throughout the Divisions. I hope that Council will find out as far as it can the number of needy dependants and let that number be known, as well as the sum of money which it thinks would be necessary to provide for them as they might reasonably have hoped to be provided for. Then I am certain that all members, including those in Divisions which instructed their representatives to support the Harrow amendment, will swiftly and generously respond to an appeal for funds.

If the event proves that dependants are being adequately cared for, the £10,000 for the fountain will also be quickly forthcoming. As I said at Harrogate, this represents the trifling sum of 3s. 4d. per member, but I fear (I hope I am wrong) that even this will not be speedily subscribed unless the position of the dependants is made clear. We are not against a visible war memorial (many of those speaking in support of Harrow's amendment made this point), but we feel that it would be wrong to spend money on any form of visible memorial if there are dependants of those killed by enemy action requiring assistance.

If Council will tell us all the facts there need be no doubts of the generosity of the profession.—I am, etc.,

JOHN WILKIE.

Lancaster.

Free Drugs for Private Patients

SIR,—It is inevitable that in the abbreviations from *Hansard* that appear in the *B.M.J.* some points should be missed. May I quote certain passages more fully, as they show a surprising admission by the Minister of Health?

As you state (*Journal*, July 16, p. 184), Mr. Richard Law moved an amendment to enable those treated by private practitioners to receive the advantages of the Act so far as pharmaceutical services were concerned. During the discussion Dr. Segal (Member for Preston), in hoping that Mr. Bevan would set his face against the amendment, said, "A tremendous concession has been made by the Minister in permitting full scope of private practice to exist alongside the National Health Service. That being so, it is more than ungenerous of the Opposition to expect the Minister to go to the length of actually subsidizing private practice, because that is what it amounts to. I hold the view that if my rt. hon. friend was tempted to give way to the Opposition on this amendment he would be sabotaging the whole of the National Health Service scheme."

I am not interested in the view of a doctor or any other person who says that a tiny modicum of freedom, unavoidably granted, is a tremendous concession. And I would have agreed with you, Sir, that this opinion was not worth quoting if it had not, a little later, drawn a remarkable confession from the Minister when he said, "We now have this 4% [of the population outside the Service]. I do not take exception to it, but I say that, if we made the concession asked for to-day, that 4% would grow very rapidly indeed, and before very long—my hon. friend the Member for Preston was right—this would prove to be the biggest piece of sabotage of the Health Service which could possibly have been conceived."

To lull the uneasy mind of the public and to make it more difficult for the profession to stay out, the Minister said last year that any part of the Service was available to anyone, to use or not as they chose. Since then he has gone back on his word with one quibble after another, and now he states that his Act depends for its success on millions being forced to use it against their will.

Here at last we have the truth. *It will out.* Even Mr. Bevan cannot hide it indefinitely.—I am, etc.,

London, N.W.1. R. HALE-WHITE.

SIR,—The question of free drugs for private patients has once more been brought before the Representative Body and once more it has been agreed by an overwhelming majority that they should be entitled to them.

We are informed that an amendment will be put before Parliament to secure this end. Presumably that amendment will be put by the Opposition, since Mr. Bevan has declared that by withholding such benefits he hopes that 100% of the population will eventually choose State medicine. The opponents of such an amendment will doubtless declare that there are insuperable administrative difficulties. The only administrative difficulties that one can see are those concerned with controlling prescribing by doctors, and this to me appears to present no special difficulties.

All doctors already in the Service could accept Forms E.C.1 overprinted with a large P, signifying that the patient wished pharmaceutical services only. Such a doctor would have x patients for whom he received a capitation fee and $x + p$ for whom he prescribed. On this latter figure his prescribing costs could be averaged. Likewise, a doctor outside the Service could apply to the executive council for admission to a "P" list for prescribing only, and here again his costs could be averaged. The latter doctor could not, of course, be fined by deducting a sum from his State remuneration for over-prescribing, since he would have no such remuneration, but if any penalty was required then removal from the "P" list could be threatened.

The system I have outlined does not imply that we approve of such fines, but it would not add any more administrative burdens or difficulties at executive-council levels than if those "P" patients came on State capitation lists.—I am, etc.,

Malvern, Worcs. G. JAMIESON MEIKLE.

*** An amendment on this subject was defeated when the Standing Committee debated the Amending Bill during its third and fourth sittings on July 5 and 6.—ED., *B.M.J.*

Clearing House

SIR,—I have just received a circular letter from my M.O.H. quoting a directive from the Ministry. This states that, "should the doctor attending the patient deem that an oxygen tent, or oxygen therapy equipment, is necessary, he must consult a specialist from a local hospital. If, after consultation, it is still found necessary to order the equipment then the ordering becomes the responsibility of the hospital."

This directive seems to be remarkable both in its implications and in its grossly offensive wording. Is it really the intention of the Minister to downgrade the G.P. to the level of a medical orderly?

There is an increasing tendency to regard the G.P. mainly as a clearing house, and the loss of confidence in his ability fostered by this can only damage the profession as a whole in addition to destroying the clinical interests of the practitioner. Moreover, this denigration of the G.P., who alone is in a position to know the patient as an individual within his own environment and not just as a series of dissociated systems, would seem to run counter to all modern medical thought.

There is an increasing feeling of frustration among practitioners, and if they are now to find their professional interests stifled at every turn by regulations of this nature then it would seem incumbent to inform young aspirants to general practice of their future status. If the best men then turn aside it will not matter; they will not be needed.—I am, etc.,

London, N.W.9. N. C. MOND.

POINTS FROM LETTERS

Waste

Dr. G. C. PETHER (Hadley Wood, Herts) writes: In a recent lett to *The Times* Sir Lionel Whitby has provided further evidence, such were still needed, that the State is less moral than its citizer Such was indeed evident, to those who would see and listen, lor before the Health Act. If this be agreed, then the ethical claims the political Left are seen for what they are—pretentious, insoler and false in every sense. . . . It has been pointed out that ar further advances in social services can only come from increas wealth and productivity. A Minister of the Crown stated some tir ago that exports do not matter. But without exports, visible ar invisible, where are the health services? If I understand him arig Dr. Ffrangcon Roberts stressed the necessity of cutting our co according to our cloth. I know a factory employing 3,000 men which the contributions of the firm for social insurance amount £30,000 a year. Such is a direct charge on manufacture, by whi we live. So it would seem that the health services can only surviv can only be financially supported on an adequate scale, if waste ruthlessly eliminated and the Government learns to keep its word.

Electronic Medicine

Dr. M. H. K. KANE (London, S.E.21) writes: Why all this fu and bother about the salaries of consultants, specialist general-practitioner specialists, general practitioners, and nurses Is it not only too clear that in a few years we will all replaced by appropriately specialized electronic brains, which w be installed in suitable batteries at our teaching hospital general hospitals, cottage hospitals, and health centres? Tl only factor lacking in this arrangement will be human unde standing, and in view of the well-known infallibility of mode mechanical aids to diagnosis this is really almost unnecessary. Tl whole troublesome profession will thus be neatly and convenient eliminated, with immense saving to the Government of worry ar expense. Large sums will be released for the provision mechanical appliances and supports for the industrial populatio whose welfare, longevity, and productivity will thus be immeasurab increased. Let us therefore relinquish our futile and undignifie endeavours to hold back the sacred waters of progress.

H.M. Forces Appointments

ROYAL NAVY

Surgeon Rear Admiral J. A. Maxwell, C.V.O., C.B.E., K.H.S., has been placed on the Retired List.

Surgeon Commander T. L. J. Barry has been placed on the Retired List.

Surgeon Commanders W. A. Hopkins, O.B.E., and T. B. Lynagh to be Surgeon Captains.

Acting Interim Surgeon Commanders D. A. Hovenden, E. B. Bradbury, E. D. Caldwell, H. G. Silvester, O.B.E., and J. L. S. Steele-Perkins to be Surgeon Commanders.

Acting Surgeon Lieutenant-Commanders A. J. Gaskell and J. Glass to be Surgeon Lieutenant-Commanders.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenant-Commander R. G. Reid, V.R.D., to be Surgeon Commander.

Surgeon Lieutenant-Commanders D. Rice and F. J. Curtis have been removed from the Active List.

Surgeon Lieutenants D. R. Tipping, E. J. King, A. W. Hagger, D. H. M. Titcombe, and J. J. Ennitt to be Surgeon Lieutenant-Commanders.

ROYAL AUSTRALIAN NAVY

Surgeon Lieutenant-Commanders J. E. Hughes and M. J. L. Stening, R.A.N.R., to be Surgeon Commanders, R.A.N.R.

ROYAL NEW ZEALAND NAVY

Surgeon Commander E. S. McPhail, V.R.D., K.H.P., to be Surgeon Captain.

ARMY

Colonels E. M. Townsend, M.C., and D. T. M. Large, late R.A.M.C., have retired on retired pay and have been granted the honorary rank of Brigadier.

Colonel D. H. Murray, late R.A.M.C., having attained the age for retirement, is retained on the Active List supernumerary to Establishment.

Colonels W. W. S. Sharpe and F. McKibbin, O.B.E., late R.A.M.C., have retired on retired pay.

Lieutenant-Colonel T. F. M. Woods, O.B.E., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel G. F. Harrison, M.B.E., has retired on retired pay on account of disability.

Major (War Substantive Lieutenant-Colonel) J. A. MacDougall, O.B.E., to be Lieutenant-Colonel.

Majors A. C. Cox, O.B.E., and A. Gleave to be Lieutenant-Colonels.

Major J. Walsh has been placed on the half-pay list on account of disability.

Captain (War Substantive Major) T. W. Carrick to be Major.

Short Service Commission, Specialist.—Captain (War Substantive Major) J. B. Headley Blythe has retired on account of disability and has been granted the honorary rank of Major.

Short Service Commission.—Captain S. J. Nathan to be Major (substituted for the notification in a *Supplement* to the *London Gazette* dated April 22). Captain J. P. Mitchell has retired and has been granted the honorary rank of Major.

Short Service Commission (Type "B").—Colonel R. H. Robinson, T.D., from T.A., to be Lieutenant-Colonel. Major H. Shield, from T.A., to be Major. (Substituted for the notification in a *Supplement* to the *London Gazette* dated April 26.) Captains J. Totten, W. S. Angus, and A. A. Grace to be Majors.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Colonels H. G. Monteith, D.S.O., O.B.E., and E. V. Whitby, late R.A.M.C., having exceeded the age limit for liability to recall, have ceased to belong to the Reserve of Officers.

Lieutenant-Colonels (Honorary Colonels) G. K. Maurice, D.S.O., M.C., H. F. Panton, D.S.O., M.C., and J. F. W. Sandison, O.B.E., M.C., having exceeded the age limit for liability to recall, have ceased to belong to the Reserve of Officers, retaining the honorary rank of Colonel

Lieutenant-Colonels J. A. Clark, M.B.E., P. C. Field, and R. H. Leigh, M.C., having exceeded the age limit for liability to recall, have ceased to belong to the Reserve of Officers.

Lieutenant-Colonel D. H. Waldron, O.B.E., from I.M.S., to be Lieutenant-Colonel.

Major (Honorary Brigadier) R. H. Lucas, C.B.E., M.C., having exceeded the age limit for liability to recall, has ceased to belong to the Reserve of Officers, retaining the honorary rank of Brigadier.

Majors (Honorary Colonels) J. H. Baird, E. Catford, O.B.E., W. B. Stevenson, and H. J. G. Wells, having exceeded the age limit for liability to recall, have ceased to belong to the Reserve of Officers, retaining the honorary rank of Colonel.

Majors (Honorary Lieutenant-Colonels) C. M. C. Byrne, O.B.E., W. Mc. M. Chesney, M.C., W. E. K. Coles, C. R. Dugeon, O.B.E., M.C., W. V. Fawkner-Corbett, O. D. Jarvis, O.B.E., D. J. H. Jones, W. J. A. Laird, and R. B. Myles, O.B.E., having exceeded the age limit for liability to recall, have ceased to belong to the Reserve of Officers, retaining the honorary rank of Lieutenant-Colonel.

Majors E. H. W. Elkington, D. G. Evans, H. G. Hobson, O.B.E., M.C., D. C. Ogilvie, M.C., T. V. Oldham, D. W. Pailthorpe, M.C., and J. C. Preston, having exceeded the age limit for liability to recall, have ceased to belong to the Reserve of Officers.

Captain (Honorary Lieutenant-Colonel) P. L. C. Carrier, having exceeded the age limit of liability to recall, has ceased to belong to the Reserve of Officers, retaining the honorary rank of Lieutenant-Colonel.

War Substantive Majors V. St. G. Vaughan, W. M. Walsh, and A. J. Daldell-Ward, from Emergency Commissions, to be Majors, and have been granted the honorary rank of Lieutenant-Colonel.

Major S. J. Nathan, from Short Service Commission, to be Major.

Majors T. K. White, W. C. Templeton, J. J. Barton, and O. Walker, from I.M.S., to be Majors.

Captain (War Substantive Major) H. Mowschenson, from Emergency Commission, to be Major, and has been granted the honorary rank of Lieutenant-Colonel.

Captain T. W. Gillespie, from Supplementary Reserve of Officers, to be Major, and has been granted the honorary rank of Colonel.

Captains W. G. Sutcliffe, O.B.E., R. P. Smyth, O.B.E., G. R. McNab, J. W. Crofton, T. G. Faulkner-Hudson, G. F. Wright, H. A. Magnus, A. E. Francis, R. S. Handley, and W. A. Oliver, M.B.E., from Supplementary Reserve of Officers, to be Majors, and have been granted the honorary rank of Lieutenant-Colonel.

Captains W. R. Cunningham, J. B. McCallum, S. T. Irwin, J. J. T. Morrison, O. C. Dobson, J. Devine, M.C., H. I. C. Maclean, R. A. Binning, H. V. Corbett, D. W. Ashcroft, E. R. Danste, E. Carew-Shaw, W. D. B. Pettigrew, P. E. Cresswell, J. Mason, M.B.E., G. A. Fowler, M. H. Hughes, P. B. Barker, I. P. J. Macnaughten, E. H. W. Lyle, W. G. France, J. P. Bostock, J. W. S. H. Lindahl, W. Mackenzie, A. M. Murray, R. A. Tennent, M.B.E., I. C. Thomson, R. R. Gordon, M.C., and F. J. Hebbert, from Supplementary Reserve of Officers, to be Majors.

Captain R. Mowbray, from Supplementary Reserve of Officers, to be Captain, and has been granted the honorary rank of Major.

War Substantive Captains A. T. Wallace and J. G. Dumoulin, from Emergency Commissions, to be Captains, and have been granted the honorary rank of Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Colonel J. P. J. Jenkins, O.B.E., T.D., has been appointed Honorary Colonel.

Lieutenant-Colonel W. A. Jackman, T.D., having exceeded the age limit for retention, has retired and has been granted the honorary rank of Colonel.

Lieutenant-Colonel J. P. McGreehin, M.C., having exceeded the age limit for retention, has retired, retaining the rank of Lieutenant-Colonel.

Lieutenant-Colonel R. H. Robinson, T.D., to be Colonel.

Major (Acting Lieutenant-Colonel) C. D Evans, O.B.E., Reserve of Officers, has relinquished his commission

Major (Acting Lieutenant-Colonel) J. P. Raban, T.D., has relinquished his commission on account of disability and has been granted the honorary rank of Colonel.

Major (War Substantive Lieutenant-Colonel) W. H. D. Patterson, T.D., to be acting Colonel.

Majors C. W. Dudley, T.D., P. Hickey, T.D., D. S. Jones, A. H. Macklin, O.B.E., M.C., T.D., A. S. Pern, O.B.E., T.D., R. O. Townend, T.D., E. Walsh, T.D., and H. S. Ward, O.B.E., T.D., having exceeded the age limit, have retired and have been granted the honorary rank of Colonel.

Majors W. E. A. Buchanan, T.D., T. L. Clark, T.D., P. Hayes, T.D., G. E. Lindsay, C. F. Mayne, O.B.E., G. Sparrow, M.C., T.D., and J. W. Wayte, M.C., T.D., having exceeded the age limit, have retired and have been granted the honorary rank of Lieutenant-Colonel.

Majors A. Willcox and G. M. R. Duffus, M.B.E., have been granted the acting rank of Lieutenant-Colonel.

Majors S. B. Faulkner, R. W. Gemmell, T.D., J. C. C. Howe, F. J. Lidderdale, M.C., I. H. Lloyd-Williams, M.C., J. E. McCartney, W. H. Milligan, O. F. W. Robinson, T.D., E. G. Snaith, T.D., G. T. Symons, A. J. Will, and C. N. Vaisey, T.D., having exceeded the age limit, have retired.

Major R. B. Quinn has relinquished his commission on account of disability.

Major A. R. Edwards, from R.A., T.A., Reserve of Officers, to be Major.

Captain J. Beattie, having exceeded the age limit, has retired and has been granted the honorary rank of Colonel.

Captain F. C. O'Mara, having exceeded the age limit, has retired and has been granted the honorary rank of Major.

Captain (acting Colonel) J. Donovan has relinquished the acting rank of Colonel.

Captains (Acting Lieutenant-Colonels) J. D. Wade and E. H. Evans to be Majors, retaining the acting rank of Lieutenant-Colonel.

Captain (acting Lieutenant-Colonel) S. Glaser has relinquished his commission on account of disability and has been granted the honorary rank of Lieutenant-Colonel.

Captains (acting Majors) J. D. Wade, J. Macrae, T. M. Park, and E. H. Evans have been granted the acting rank of Lieutenant-Colonel.

Captains W. H. Wolstenholme, O.B.E., T.D., R. Mowbray, and R. G. W. Ollerenshaw to be Majors, and have been granted the acting rank of Lieutenant-Colonel.

Captains (acting Majors) M. N. S. Duncan and P. G. McGrath to be Majors.

Captains H. F. T. Macfetridge, D.S.O., E. V. Bevan, A. W. Forrest, A. C. C. Burn, E. Parry, J. S. H. Wade, H. H. Kenshole, D.S.O., T.D., L. H. Allan, D. B. McVittie, A. V. Griffiths, C. S. M. Hutson, T. C. MacInnes, P. G. Seed, M.B.E., G. Bourne, and L. W. Lauste, M.B.E., to be Majors.

Lieutenant L. J. Haydon to be Major, and has been granted the acting rank of Colonel.

Lieutenant L. Fletcher, O.B.E., to be Captain, and has been granted the acting rank of Colonel.

Association Notices

B.M.A. LECTURES

Every Branch and Division may have one B.M.A. Lecture a year. The lecturer, who is chosen by the Branch or Division, is an authority on his particular subject. He is invited from the Central Office and receives an honorarium and his expenses. Branch and Divisional secretaries making up their programmes for the forthcoming year are invited to send requests to Headquarters for B.M.A. lectures. The application should be on a special form obtainable from Headquarters denoting the name of the lecturer, the subject, and choice of dates.

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of 50 guineas.
2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.
3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.
4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1949. The prize will be awarded at the Annual General Meeting of the Association to be held in 1950.
5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.
6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.
7. Preliminary notice of entry for this competition is required, and a form of application can be obtained from the Secretary.
8. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.
9. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.
10. Inquiries relative to the prize should be addressed to the Secretary.

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1950. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1950 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1950. The title of the proposed essay and the motto should also be notified in writing to the Secretary by Dec. 1, 1949, and a form for this purpose can be obtained from the Secretary. The prize will be awarded at the Annual Meeting of the Association to be held in 1950. Inquiries relative to the prize should be addressed to the Secretary.

PRIZES FOR MEDICAL STUDENTS, 1950

The Council of the British Medical Association is prepared to consider the award in 1950 of prizes to medical students for essays submitted in open competition.

The subject of the essays shall be "Clinical Teaching in Relation to the Practice of Medicine."

The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for a prize.

If any question arises in reference as to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. In determining the number and the value of the prizes to be awarded the Council will take into consideration the number of essays received. Should the Council decide that no essay entered is of sufficient merit, no awards will be made.

Each essay must be typewritten or legibly written in the English language, on one side of the paper only, must be unsigned, and must be accompanied by a form of application which can be obtained from the undersigned. Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than Dec. 31, 1949. Inquiries relative to the prizes should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

CHARLES HILL,
Secretary.

Diary of Central Meetings

JULY

26	Tues.	Proprietary Medicines Committee, 2 p.m.
27	Wed.	Committee on the Postgraduate Education of General Practitioners, 2 p.m.
28	Thurs.	General Medical Services Committee, 11 a.m.
28	Thurs.	Publishing Subcommittee, 11 a.m. (adjournment from July 14).
28	Thurs.	Committee on Psychiatry and the Law, 2 p.m.
29	Fri.	Public Health Committee, 2 p.m.

Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH.—At Brancepeth Golf Club (five miles west of Durham City), Thursday, July 28, 12.30 p.m., annual meeting.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 30 1949

PROBLEMS OF AGEING AND CHRONIC SICKNESS*

BY

A. P. THOMSON, M.C., M.D., F.R.C.P.

Professor of Therapeutics, University of Birmingham; Physician, United Hospitals, Birmingham

The Problem

In the short span of 150 years the progress of medicine has been chiefly responsible for two distinct problems of population in Western Europe. In Great Britain, for instance, during the first part of that period the reduction of infant mortality and the control of infectious disease led to a rapid and embarrassing increase in the number of youthful inhabitants—from about nine millions in 1801 to forty millions at the close of the nineteenth century. Decline of the birth rate and emigration checked the increase, but the astonishing advance of curative medicine in the past 50 years has so prolonged the average duration of life that the total population is to-day larger by ten millions, and of the fifty millions in this country now no fewer than seven millions are over 60 years of age. As it is inevitable that in the immediate future the proportion of the aged will increase, and that the survival of individuals with chronic maladies will be greater, the urgency of the problem of the proper provision for the chronic sick and aged needs no emphasis. It has not indeed been neglected. Within the past two years this College (1948) and the British Medical Association (1947, 1948) have published reports from special committees on the care and treatment of the elderly and infirm, and in addition there have been a number of papers from individuals whose work lies mainly in this field. The relevant literature is interesting and abounds with suggestions for reform. There is a general demand for better classification of the patients and for their segregation, like with like, in appropriate institutions; the need for special housing for the old is emphasized, and a plea is made for the establishment of yet another medical specialty in the shape of geriatrics.

When I sought, however, for some factual and statistical analysis of the patients now in the institutions and for precise information about how they got there and why they stayed so long I often sought in vain, though Affleck (1947) in his psychiatric approach to the problem included some valuable figures, to which I will refer later. Lack of dispassionate statistical analysis is a weakness in these reports, and as there is nothing in the literature from the hospitals for the aged and chronic sick that compares, for instance, with Sheldon's (1948) account of the condition of the old people living in ordinary homes in Wolverhampton I decided to undertake an independent investigation; in addition it seemed probable that conditions would vary in different parts of the country.

The Position in the Midlands

In the Birmingham Hospital Region, which includes five counties with a population of 4.2 millions, there are 50 institutions concerned with the reception of the aged and chronic sick. Their variety is remarkable; most of them are small and understaffed, with old and dingy buildings and poor equipment. Some are parts of acute general hospitals; none have been well designed for their present use, and the concern expressed by the Nuffield Surveyors for the fate of their patients was amply justified. Most of these institutions have other functions, of which the most important is the accommodation of poor and homeless people who, though not sick, are in general unable to fend for themselves.

The number of beds available (apart from those for the insane and simply destitute) in these 50 institutions is 5,780, and of these no fewer than 2,400 are contained in five large establishments in densely populated areas. For comparison the total available for general medical and surgical use in the acute hospitals is only 5,960, but in addition there are about 1,000 beds for the same purpose in the teaching hospital. Briefly, of every 100 beds for general medicine and surgery in the region at least 45 are reserved for the chronic sick. This large proportion was to me surprising.

Dr. Richard Padley, of the University Department of Medical Statistics and Statistical Officer to the Regional Board, to whom I am indebted for these figures, also made an estimate of the staff employed in caring for the chronic sick (excluding medical and laboratory services), and found at the end of 1948 that 3,650 persons were so engaged. In other words 100 chronic beds required on average a whole-time staff of 61, made up as follows: trained nurses, 4; assistant or other nurses, 21; domestic workers, 22; laundry, 4; maintenance, 5; administration, 5. These are serious figures; with an ageing population it is obvious that the staffs necessary for institutions of this kind may soon become a serious drain on the national reserve of man-power.

The field to be explored was so extensive and the problems were to me so novel and perplexing that it seemed

*The first of two Lumleian Lectures delivered before the Royal College of Physicians of London on April 5 and 7.

impossible to investigate all the institutions closely, and I decided to concentrate attention on the largest—the Western Road Infirmary in Birmingham—and to be content with occasional visits to others.

First Impressions of Western Road

My most vivid impression of the chronic wards of this hospital is of an atmosphere of profound apathy. The patients seldom spoke to each other; they rarely moved, and although there was a library service and newspapers were provided it was exceptional to see one reading. At first we thought that this unnatural calm was a consequence of discipline imposed in preparation for our visits, but we were assured it was not so and that there was nothing unusual in it. Even when we were hours together in a ward and examined in turn every patient in it the prepotent sense of still foreboding and quiet resignation endured.

Contact with the patients was not difficult; histories of their social background and infirmities were mostly accurate and readily given, but what made them remarkable was the conspicuous absence of emotional overtones as they recounted them. There was no bewailing of their fate, no clamant sense of grievance, and they spoke of life's adventure with the detachment of a disembodied observer rather than with the passion of a participant. One old lady told us a strange story of many years of colourful life breeding and breaking ponies in the Welsh Marches, of visits to country fairs to sell them, of strange adventures in wild country, and of independent freedom rarely to be attained in England now. An accident crippled her and she had been long in bed. Her face was immobile as she spoke; the glory and the zest had departed; she was interested mainly in her tea, which was a little late. Food, indeed, was their major interest; it was astonishing how much they ate. Nearly all of them were well nourished, and most of them were stout. The wards came momentarily to life at meal-times.

Apathy prevailed also in the large rooms for those who were able to dress and move about: they sat listlessly and in silence; the men smoked as long as their tobacco lasted. In these rooms there was a striking difference between the sexes: the women were much more careful of their personal appearance; they were cleaner, their clothes were neater, and they were more readily responsive when addressed. Nearly all the women had capacious bags in which they collected a strange and pathetic assortment of trifles of little value—fragments of food, bits of cloth, and empty boxes. Both rooms emptied several minutes before a meal, and long queues were formed at the doors of the dining-hall, in which there was strict segregation of the sexes; even the married couples did not sit together, and they rarely expressed any wish to do so.

We were warned that the prevailing calm was sometimes broken by outbursts of petulant misbehaviour which were commonly the result of childish jealousy, resentment, or misdemeanour. Pilfering was common and led to trouble. The manner of the theft was often ingenious and astute. One man coveted the pipe that belonged to another who also had half a crown. The pilferer, although almost incapable of movement, got up one night and stole the half-crown. A little later he bought the pipe with the money he had stolen from its owner. The men who were up and about had another interest besides food—they gambled. Nearly every morning there was an hour of feverish activity in which they studied the racing information and arranged their bets for the day. The results they heard on the radio. Football pools were not neglected. Officially their financial resources were limited to five shillings weekly allowed to them out of their old age pensions, but a few earned small sums in addition by doing odd jobs. They had considerable freedom, and when fit enough and in the humour they went into the city on social occasions; not rarely they were drunk on their return. Some of the more adroit deposited their old age pension books with friends outside the institution and managed to retain the whole sum by drawing it when they went visiting. One old woman had defeated the regulations of authority in this manner for over two years; she had glorious "blinds" on the proceeds and was a source of considerable trouble. In the acute wards the atmosphere was like that of an ordinary general hospital. Most of the patients had been admitted from their homes but a short time before; they were interested, and still hopeful of recovery sufficient to allow them to gather up the threads of their customary way of life. It was here alone that we saw any evidence of anxiety; in the chronic wards there was the apathetic indifference I have described and in others there was frank psychosis, but in none of these was anxiety prominent.

The records of the patients in the wards for the deteriorated showed that many of them had passed from the acute block to the chronic beds, where later they had developed incontinence or other unpleasant antisocial habits which led to their transfer to this final refuge. Whether the process of decay is inevitable or whether it is caused or accelerated by the apathy surrounding the chronic beds is a matter worthy of consideration.

Medical Treatment

The medical treatment in Western Road Hospital was surprisingly good, although there were only five whole-time medical officers, including the medical superintendent, to care for 1,000 bedridden patients, and they had in addition many other responsibilities—a large venereal department, 150 patients who were up and about but unfit to return to their homes, and 300 inmates, including provision for maternity, under the control of the Social Welfare Committee set up by the National Assistance Act. My registrars made frequent visits, took histories, and made clinical examinations of the standard usual in a teaching hospital, and each week the staff of the infirmary, my registrars, and I spent a long afternoon together in the wards comparing the result of our separate observations. It was rarely necessary to change a diagnosis or possible to modify treatment. A considerable amount of laboratory and radiological investigation had been done in the departments of the Dudley Road Hospital close by.

The individual case records were, it is true, brief and to the uninitiated almost incomprehensible, and they were, unfortunately, unsuitable for exact analysis.

In this connexion I have used the words "medical treatment" in their narrowest sense to signify the therapeutic use of rest and drugs, because in the infirmaries no other form of treatment is generally possible. In Western Road no masseuse had worked for years; there was a room reserved for physiotherapy, but on the door of it was the notice "Do not enter," and within was a heap of electrical apparatus apparently in good order. Rehabilitation could not be attempted, because there was no staff and all the day rooms were full of beds; there was no occupational or diversional therapy, but a few women patients knitted and did needlework. I never saw a man engage in any spontaneous activity in the wards.

Nursing

Of the nursing in Western Road Infirmary I find it difficult to speak with due restraint. When we began our survey the patients were roughly classified thus:

	Males	Females	Total
Group 1: Bedridden	393	550	943
Group 2: Allowed up but unfit for transfer to homes without nursing care	67	73	140
	460	*623*	*1,083*
The number of incontinent patients among those confined to bed	162	295	457

In addition there was a small maternity ward and a considerable venereal-disease department.

The number of full-time nurses was 181; there were besides 90 half-time nurses, and if they be reckoned as the equivalent of 45 the total available was 226. Only 14 of these were State-registered; the remainder were either assistant nurses or in training.

These figures were given to us before we went into the wards, and I was prepared for an unpleasant experience: it seemed certain that we would find bedsores, dirty beds with the inevitable foul smell, and general untidiness and lack of cleanliness.

The truth was the exact reverse. The wards were clean, the beds were impeccably made (indeed, as we found later when studying consequent deformities of the feet, they were too well made and too firmly tucked in), there was no smell or untidiness. We were quite ruthless and perhaps a little rude in our first inspection; we pulled down bedclothes here and there looking for bedsores and dirty beds and found none. There were only nine bedsores in the whole institution, and these were in cases of gross organic nervous disease in the last stages.

Two nurses were on duty in wards containing 70 patients, of whom 30 were incontinent; they never stopped working—they did not come to speak to the doctor of the ward or to the matron unless they were sent for; quietly and efficiently they went on with their job. In the incontinent cases the backs "were done" every four hours day and night.

The equipment of the wards was lamentable; basins with running water were few and far between, the sluice-rooms were mainly archaic, though here and there a bed-pan washer had been installed; there were no pulleys over the beds; the baths were of the ordinary domestic type—the bedridden were wheeled to them once a week and laboriously lifted in and still more laboriously lifted out. Many of the women patients could not do their own hair, and yet it was tidy and obviously tended regularly by the staff. At night one assistant nurse was in charge of the 70 beds; to turn a helpless patient she had to fetch a nurse from another ward and render her the same service in return. The relations between the staff and the patients were good; in our later clinical examinations we heard frequent spontaneous tributes to the kindness of the nurses, and we were surprised at the extent of their knowledge of the social background and personal predilections of the patients.

Conditions such as these are by no means exceptional. In many institutions in the Birmingham Region they are much worse; in few are they as good. For instance, at Exhall Hospital, in Coventry, there were only two resident nurses for 274 patients of the same sort; at night there were often not enough to allow one to each ward of 50 beds, and "runners" were employed to call nurses when and where they were most needed. Yet the work was done; we found the wards clean and the patients well tended and without bedsores. In the smaller hospitals classification of the patients was impossible, and we saw babies and young children in beds side by side with senile dements.

In their quiet endurance and their efficiency, as in their triumph over discouraging circumstances and lack of proper equipment, the nurses recalled the virtues of their fathers in the rank and file of the county regiments who held the trenches in Flanders in the campaign of 1914–18 and saved Europe. Certainly by their work they have delivered the hospitals of this country from chaos, for if the infirmaries fail the work of the general hospitals will be speedily stifled by the accumulation of cases of chronic sickness in their wards.

Rivers of ink have already flowed into the sterile sands of controversy about the nursing problem and I do not wish to add to them. I confine myself to the statement that the work of nursing in the hospitals of this country is most inequitably distributed; that a disproportionately heavy burden is borne by the staffs of the institutions for the chronic sick; that, despite neglect and poor equipment, the most heavily burdened have done their work efficiently and humanely, and their triumph owes little to theoretical instruction, academic distinction, or flowers and shampoo-rooms in the nurses' homes.

These simple facts should be considered by those whose duty it is to shape the future of nursing. Kindness, courage, practical resource, and patient endurance of the routine of daily work are qualities more valuable in nurses than a superficial knowledge of the intricacies of anatomy and physiology. It may be that the pursuit of a high average of academic attainment for State-registered nurses is a mistake. It might be better to select a small number for intensive training for positions of responsibility as sisters, matrons, and administrators and to rely more on character and practical work in the wards as the test for registration for the great majority. Unless some change is made it is certain that for many years defects of primary education will exclude a large number of excellent and intelligent nurses from the ranks of the registered. In any event the condition of the sick in the infirmaries demonstrates the foolishness of the contention that the measure of the efficiency of the nursing staff is the average duration of the stay of the patients in hospital.

The recently published Report of the Working Party on the Recruitment and Training of Nurses is not a distinguished document, but paragraph 247 deserves notice for its almost incredible stupidity. It runs: "It is clear that for some time to come, owing to the shortage of trained staff, it will be essential to continue to use the services at least of those assistant nurses now recognized and employed. Such evidence as we have been able to obtain points to the fact that useful service can be rendered in the nursing of mental and tubercular patients and probably also of fever patients and the chronic sick by persons who are not fully trained nurses." For many years four out of five nurses responsible for the care of the chronic sick have not been fully trained. I have paid my tribute to their skilful and devoted work and hope they will not be distressed by this slighting reference in the report.

Tentative Conclusions Based on Pilot Survey

Our preliminary survey was undertaken to discover whether improvement in the staffing and equipment and the application of the standards of investigation and

RELATIVE AGE DISTRIBUTIONS OF PATIENTS IN WESTERN ROAD INFIRMARY

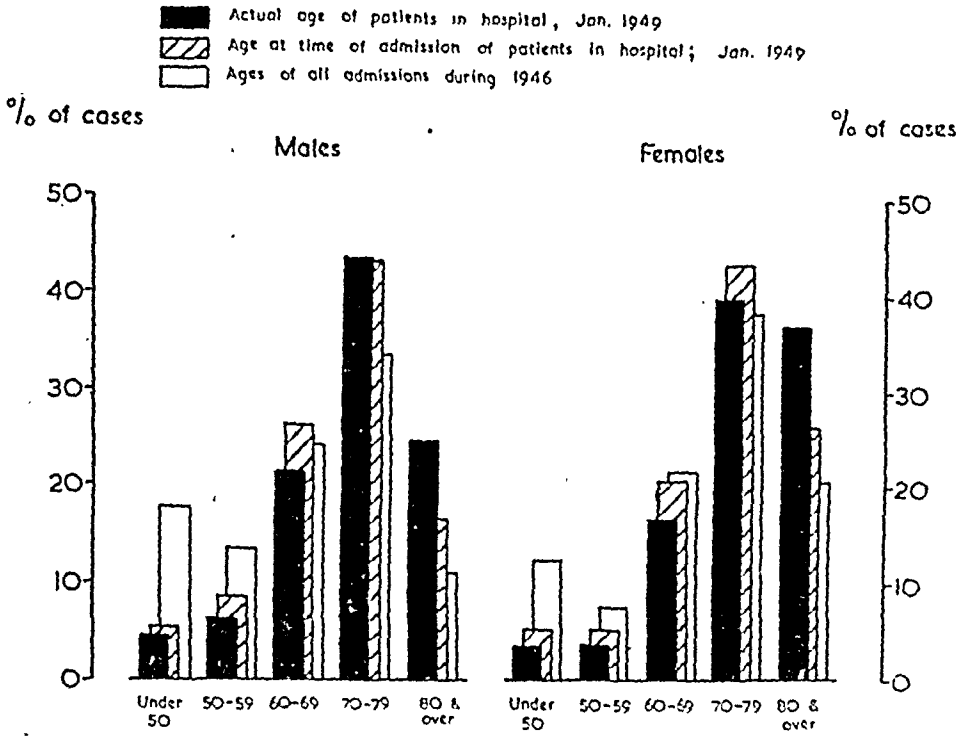

CHART 1

treatment of a good general hospital would be likely to ameliorate the condition of the chronic patients to such a degree that they would be able to return to their own homes. We were soon convinced that improvement of that extent is quite impossible for the great majority, although a number might be made fit enough for transfer to institutions in which a more active and congenial life is possible than in a hospital for the chronic sick.

The reasons for that discouraging conclusion are three. First, nearly all the patients are the victims of pathological conditions which are either degenerative or genetic in their origin and beyond the scope of therapeutics in its present stage of development. Secondly, long confinement to bed without occupational or diversional therapy, without massage and passive movement in hospitals so grossly understaffed that independent activity of any kind has been discouraged for fear of accident, has led to rapid deterioration in the shape of contractures, deformities of the feet, and the development of incontinence. Thirdly, and probably the most important, is the subtle disintegration of human personality that is so common in these patients. Many literally do not wish to leave the beds in which they have lain so long; several refused admission to my wards in the General Hospital for the reason that if they were cured they might be compelled to leave the infirmary and resume the struggle of life alone. Like T. S. Eliot's women in the Cathedral at Canterbury, they did not wish anything to happen: they wished to be left to perish quietly. We had to comfort others by telling them that we had no intention or desire to discharge them before they would consent to give a history or co-operate in examination. Whether the establishment of homes in which a certain amount of nursing and domestic help is provided would encourage many of these patients to leave the infirmaries willingly is a matter to be decided by trial. I am not very hopeful of the result of such an experiment. I feel that most of the inmates in the chronic wards must be regarded as a sad inheritance from a long period of neglect—like many of the deteriorated patients in the mental hospitals—and that the opportunity for effective treatment has long since been lost.

At this stage it was clearly necessary to check the accuracy of our impressions by reference to statistical control. My colleague, Professor T. McKeown, of the Department of Social Medicine, with one of his senior lecturers, Dr. C. R. Lowe, came to our help and devised record forms suitable for mechanical sorting and analysis. The students of the University of Birmingham made us a grant of £1,000 to pay the cost of the investigation. At a later date Birmingham Regional Hospital Board, at the suggestion of the Hospital Management Committee at Stoke-on-Trent, sanctioned a similar survey in the Potteries, and soon we hope to arrange another in the rural peace of Herefordshire. The final figures will be published independently from the Department of Social Medicine, but by the kindness of Dr. Lowe I am able to present the results of a pilot survey, based on a preliminary analysis of the records of 714 patients—318 male and 396 female.

Age, Mobility, and Mental Condition

The mean age of the males is 74 years and of the females 76; 92% of the males and 95% of the females are 60 years and over; 70% of the males and 71% of the females are over 70 years; and 27% of the males and 37% of the females are 80 or over (Chart 1). The largest ten-yearly group for men is from 70 to 79 years and for women from 75 to 84; both these groups are 43% of the respective totals. Clearly the outstanding characteristic of the patients in this infirmary is advanced age.

Of the 714 patients 394 were completely bedridden (49% of the males and 60% of the females); of the remaining 320 only 56 men and 13 women were fit enough to venture out of doors.

At the time of the survey we judged that all but 5% of the bedridden were beyond hope of rehabilitation, but unfortunately it was impossible to determine accurately what their condition had been at the time of admission. We believe that their complete disablement has been in some measure due to continued rest in bed and to a large degree has been aggravated by it, because later we found suggestive evidence that a considerable proportion of the patients had been admitted from their homes simply as a consequence of some domestic upheaval and not on account of deterioration of their condition.

Sixty-three per cent. of the men and 52% of the women were reported to be "occupied" in the sense that they would occasionally read, write, knit, or help in the ward. My own observation, already recorded, suggests that this estimate is excessive. In Affleck's survey at Leeds he included 788 patients in five separate and much smaller hospitals; their age distribution and rough clinical classification corresponded well with ours, but the proportion of bedridden was much lower (in Leeds 33.9% of the males

and 41.7% of the females). Affleck does not give any figures of the nursing staff available, and it may be that the difference between the two groups was due to greater activity in Leeds than was possible in the wards at Birmingham.

Mentally we classified 32% of the males and 39% of the females as abnormal and in so doing ignored senile forgetfulness, irritability, and other minor manifestations of elderly decrepitude; we considered 25% of all the patients certifiably insane. These figures are in exact agreement with Affleck's estimate of 37.3%, and give further support to the explanation suggested by Lewis (1946) of the difference between the first admissions to English and American mental hospitals of patients over 65 years of age. The difference is not in the incidence of psychosis but in the method of dealing with it. In England a large proportion of these cases are cared for in the hospitals for the chronic sick, and in America they are in the mental hospitals. In England many patients thus escape the statistical analysis of the Board of Control.

Affleck believes that the vast majority of the mental disorders among the chronic sick are organic in basis, although he admits the possibility of the importance of functional elements derived from hopelessness and lack of interest. The reason for his belief is the undoubted fact that in nearly all these cases it is easy to elicit evidence of somatic disease such as arteriosclerosis, cerebral thrombosis, and cardiac insufficiency. On the other hand, in ordinary clinical practice cases of that type are common with no evidence whatever of mental failure.

I confess that I am left with the uneasy suspicion that much of the psychiatric disorder in the institutions for the chronic sick may be the result of their apathy and routine; no dogmatic statement, and indeed no opinion, is justified at the present time. What is needed is a systematic study of the mental and physical condition of the patients at the time of their admission to the infirmaries and of their subsequent progress. Such study has hitherto been impossible because the institutions for the aged and chronic sick have been neglected by both physicians and psychiatrists and because their staffs have been too small and too overburdened with routine work to undertake it.

Marital Status

Of the men 58% are widowers, and of the women no less than 73% are widows. Both these figures are significantly higher than those for similar age groups in the general population of Birmingham. The proportion of the unmarried in the infirmary is also higher than outside. The result is conveniently illustrated in Chart 2, which shows that, if a man or woman is married and the mate survives, the risk of ending his or her days in an infirmary is considerably reduced—a conclusion that may bring comfort to those who worry about the social institution of marriage. In Leeds only 34.5% of the men were widowers and 59.3% of the women widows.

Duration of Stay

The mean duration of stay for males was 34 months and for females 37 months (the range in both sexes from 0 to 18½ years); 26% of the men and 28% of the women had been in the infirmary for more than three years; 71% of the women and 62% of the men had been there for a year or more. These figures do not represent the work of the infirmary accurately; they leave an impression of a slow drift to inevitable death over a period of many months, and this is far from the truth. During 1948, for instance,

MARITAL STATUS (Patients 65 years and over) compared with 1939 National Registration, Birmingham.

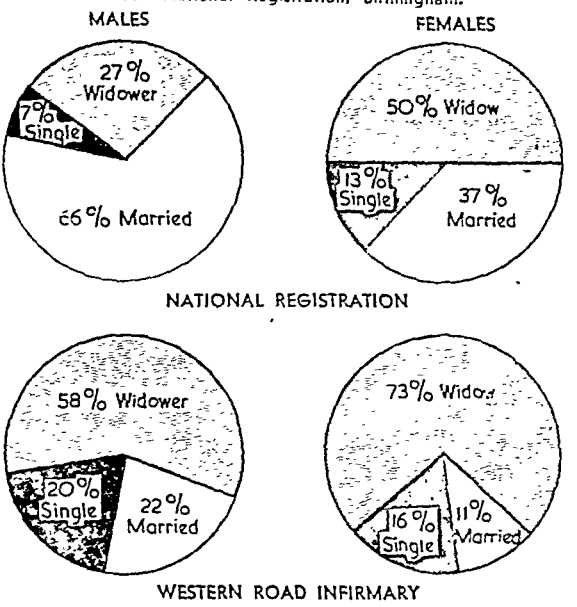

CHART 2

there were 958 deaths in the institution; of these 656 (68%) occurred within 100 days of admission and no fewer than 548 (57%) within 50 days; only 12% of those that died had been in Western Road for two years or more. Clearly an important part of the work was the treatment of acute illness in old people, and we decided to investigate this aspect of the problem more closely by reviewing the subsequent history of every patient admitted during one year. Mr. Broad, the clerk in charge of the records at the infirmary, who had already supplied us with the figures relating to the deaths in 1948, undertook the formidable task of preparing a summary of the case histories of 2,478 patients admitted between Jan. 1 and Dec. 31, 1946 (Tables I and II and Chart 3), and Dr. Padley has provided me with the following analysis:

TABLE I.—*Admissions, Western Road Infirmary, 1946*

Age	Males	Females	Total
Under 50	260 (17·7%)	124 (12·3%)	384 (15·5%)
50–59	199 (13·5%)	75 (7·4%)	274 (11·1%)
60–69	357 (24·3%)	218 (21·6%)	575 (23·2%)
70–79	493 (33·5%)	384 (38·1%)	877 (35·4%)
80–	161 (11%)	207 (20·5%)	368 (14·9%)
Total	1,470	1,008	2,478

TABLE II.—*Fate of Patients Admitted in 1946. Period of Follow-up 26 Months*

	Males	Females	Total
Died:			
In less than 4 months	437 (29·7%)	355 (35·2%)	792 (32%)
In 4 to 26 months ..	115 (7·8%)	82 (8·1%)	197 (7·9%)
Discharged:			
In less than 4 months	784 (53·3%)	385 (38·1%)	1,169 (47·1%)
In 4 to 26 months ..	93 (6·3%)	103 (10·2%)	196 (7·9%)
Survived	41 (2·8%)	83 (8·2%)	124 (5%)
Total	1,470	1,008	2,478

Months are lunar months of 28 days.

The fallacies attending conclusions drawn from a survey of patients within a short period of time are at once apparent, because large numbers of chronic patients will

accumulate over years and distort the picture of the work done. More detailed analysis yielded some interesting results: (1) Men are admitted to the infirmary at an earlier age than women; only 44% of male admissions are 70 years or over, whereas 58% of the females are of that age group. (2) No less than 32% of all admissions died within four lunar months and in the same period 47.1% had been discharged. (3) In 26 months a further 15.8% of the patients either died or were discharged (7.9% in each group). (5) Only 5% of the total admissions survived 26 months or more, and in this group the proportional survival of women was three times greater than that of the men (8.2% as against 2.8%). To adopt a simile suggested by Lancelot Hogben—the patients entering an infirmary are like a crowd of old people passing slowly through a gate into a long avenue. Within four months more than three-quarters have left the avenue either by death or by return to their homes. In two years 19 out of 20 have gone and only a few remain passing through the shade: these stragglers may long survive, and their accumulated numbers at a given moment of time give a false impression of the true condition of life within the grove.

TABLE III

	Western Road, Birmingham	Orsett Lodge, Essex
Total admissions in one year	2,478	1,430
Aged 60 years and over ..	1,820 (74%)	780 (55%)
Under 60 years	658 (26%)	650 (45%)

TABLE IV

	Western Road, Birmingham	Orsett Lodge, Essex
Total admissions	1,820	780
Died	902 (49%)	296 (38%)
Discharged	807 (44%)	284 (37%)

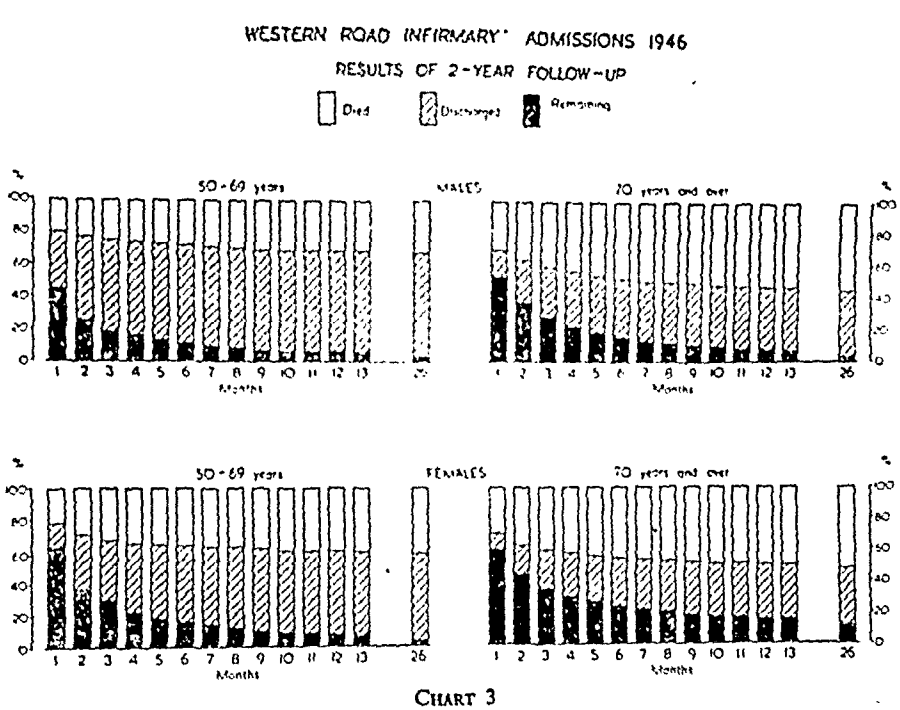

CHART 3

A hospital for the chronic sick is a bad description of Western Road Infirmary, and I suspect for many others. Most of the patients admitted are acutely ill, and their treatment is undertaken in an institution without a laboratory or radiological department and with a staff so small that it is remarkable that the treatment and the nursing were as good as we found them to be. It is true that the clinical and laboratory staff at Dudley Road Hospital, close by, had given all the help that lay in their power, but it would not be candid to pretend that the arrangements were satisfactory. The taking of a radiograph involved a journey of half a mile, and many of the patients were unfit for such adventure; in any event the radiological department was too small for the needs of the acute hospital and desperately overworked. The difficulties of laboratory investigation by messenger and transport of specimens need no elaboration.

I have compared Dr. Nagley's results at Western Road with Mr. Cosin's (1948) at Orsett Lodge Hospital, in Essex. At Western Road the number of admissions was greater than at Orsett and the proportion of older patients was also larger (see Table III). Cosin does not deal with the fate of the patients under 60, and a comparison of those over that age gave the result shown in Table IV. It seems likely that the greater proportion of deaths at Western Road was due to the greater age of the patients. What is surprising is that the ratio of discharges to admissions in this age group was also larger in Birmingham, because at Orsett there was an active department of physiotherapy and there was none at Western Road. The inference is that the discharge of an elderly patient from an infirmary depends more on the condition of his home than it does on the attention of a masseuse.

Prelude to Admission

No less than 77% of all the patients were admitted direct from their own homes; not more than 18% had passed through a general hospital, and of this number one-sixth had passed through the general hospital in a technical sense only — that is, they had been sent on to the infirmary from casualty and out-patient departments and had not been in the wards. In brief, six out of seven patients had been admitted to this understaffed and ill-equipped institution without adequate investigation or treatment. To the credit of the general practitioners of Birmingham it should be recorded that in more than one-half of the patients admitted to the infirmary under the age of 60 years some form of laboratory or other investigation had first been undertaken in the difficult circumstances of their own homes. The figures are in striking contrast with those from Leeds, where it is stated nearly all had been thoroughly examined in hospital.

A study was made of the medical and nursing attention required by individual patients at the date of admission, and it was found that in 33% all that was needed was a visit from a doctor once a month; this group had no skilled nursing of any kind at home, and it was clear that the only reason for their entrance to the infirmary was some sort of domestic catastrophe such as the death of a spouse or friend or illness of the person who had previously cared for them. These cases are entirely a social problem; for the most part they needed only help in their houses or untrained attention to their physical disability. The estimate of 33% is a conservative one; when there was any doubt about a particular case it was excluded from the group. It was clear that many of these patients had

deteriorated in the infirmary—a consequence, we believe, of the prevailing apathy and of prolonged rest in bed. That so large a proportion as one-third of all the patients had been admitted without disability sufficient to require admission on medical grounds lends support to the suggestion of Brooke (1949) that social services organized by the hospital to care for the elderly in their homes might save many of them from the last dreary journey through an infirmary to a squalid tomb.

Investigations at Highbury, a home for 270 old people in Birmingham under the administration of the local authority, warranted the same conclusion. In this institution the mean age of the patients was 78, higher than it was in the infirmary, and they were living a much more active and pleasant life at a weekly cost of less than half that of an infirmary bed. Had this home not existed we were satisfied that a very large proportion of its inmates would have required accommodation in an infirmary. There is some dispute about the proper size of such homes, and the National Corporation for the Care of Old People favours small ones for 25 to 30 residents. The master and matron of Highbury were convinced, on the other hand, that in large cities homes for old people should ideally have about 400 beds, and that most of these should be in small separate rooms, some with two beds for married couples.

When I asked whether the provision of separate rooms would not make the cost of domestic service prohibitive they replied that, on the contrary, it would solve the problem, because nearly all the old people would keep their own room spotlessly clean without help, but many of them resented cleaning part of a dormitory. Their main arguments in support of their preference for the large home were that the old people of the cities liked the atmosphere and bustle of a crowd, that communal entertainment in the shape of films, discussions, and stage shows was much more easily and better organized than in the small homes, and that the feeding would be better and more economically done.

Attitude to Leaving the Infirmary

One-third of all the patients were unwilling to leave the infirmary in any circumstances; as I have already said, the mere suggestion that they might be made well enough to do so distressed them seriously, and we found that this frame of mind was directly related to the duration of their stay in the institution. Thus, within the first three months of their admission 65% of the men and 71% of the women are eager to return home, but after four years the figures fall to 45% of the men and 28% of the women, and I am sure that the fall would be even greater if the patients were actually confronted with the opportunity of leaving. In part this reluctance to leave is due to the disintegration of their homes, for we found that more than half (57%) of all patients had no home of any kind to which they could go if they were discharged. Of the 270 patients with a home available to them less than a half (44%) could expect any form of help in the house, and more than one-half (56%) would either be compelled to live entirely alone or in a house deserted during working hours.

It is significant that during the first three months of their stay 71% of the males and 51% of the females have a home to which they would be welcome on their return; thereafter the home and family background progressively recedes and after four years only 24% of the males and 13% of the females have any sort of home available to them. Manifestly the cohesion of the homes of the elderly is fragile: absence for more than three months is sufficient to damage it; in four years more than three out of four of their homes have vanished. Two problems emerge clearly from this analysis: the first is concerned with the maintenance of the elderly home, and the second is that of provision of adequate treatment and social help for the old when they fall sick.

Factors Affecting the Cohesion of the Home

Psychologists and social anthropologists agree that the forces which promote cohesion in a group are derived from fundamental instincts modified by habit and custom and, to a very slight degree, by rational considerations. The instincts are of two kinds—the self-regarding and the group-maintaining: the first are the instincts of self-protection, sustenance, and assertion, and the second those of mating, nursing, and the herd. At the most primitive level these instincts were satisfied by the organization of society in family groups, but the passion and pugnacity inseparable from mating led to the institution of exogamy to avoid the internecine strife that ensued from sexual selection within the family. Exogamy established the tribe as the social unit; conquest and enslavement of the conquered made the nation. The discipline of law with the habits and customs that it implies maintains the cohesion of a people so long as the makers of the law are wise enough to see that its system does not conflict unduly with the fundamental instincts that lead to the development of society or with its interests.

It is the opinion of many with long experience of the work in institutions for the chronic sick and aged that the sense of family unity and responsibility is weakening, and that people in this country are less interested than they were in the fate of their elderly and disabled relatives. We are also told that parents to-day are not as willing to sacrifice personal comfort and pleasure in the interests of their children, and that many children at the age of puberty or soon after lose all sense of responsibility and affection for their family.

Accurate estimation of the value of evidence of this kind is difficult, because it emanates from those whose work constantly brings them face to face with the tragedy of the broken home and their judgments may be unduly melancholy. Sheldon's (1948) report on the old people of Wolverhampton shows how ardently the flame of family affection may burn despite discouraging circumstances, and suggests that the evidence should be accepted with caution. It would be unwise, however, to neglect it, for it comes from many sources and its volume is increasing.

The loosening of the ties of English family life and the rapid increase of divorce attracted serious attention in 1918 at the end of the first world war and have become more pronounced during the past 30 years, especially in the period of the second campaign.

Disruption of a family by conscription and long terms of separation inevitably diminished cohesion; so did unemployment and the application of the means tests in the uneasy period of truce. During the industrial depression many a father found his dignity and authority as the main support of a family replaced by a sense of ignominious dependence on the earnings of children, who sometimes resented the burden of the maintenance of their parents' home.

The deplorable condition of houses and their overcrowding made the position of sick and disabled members of a family increasingly difficult, and the burden of their care in restricted accommodation seemed intolerable. Many social workers regard this factor as the predominant one, and it is often pressed in argument by those who seek a bed in an institution for a dependent relative. It cannot,

however, be alone responsible for the increased demands on the infirmaries, because, first, the overcrowding of houses is less than it was 50 years ago, when the average size of families was larger, and, secondly, applications for institutional provision often come from those who cannot reasonably claim that their housing accommodation is unsatisfactory. It is difficult, too, to induce families to take back their relatives when new houses are available to them. Clearly there is now less reluctance to seek the aid of public assistance in solving the problems of family life. The administration of the infirmaries has become more sympathetic and humane, the horror of the Victorian union is no longer so deterrent, but it is also possible that slackening of the moral fibre of the family and a demand for material comfort and amenity outweigh the claims of natural affection.

A shorter working week for men has encouraged the employment of women in industry; homes therefore have less attention at a time when they are difficult to run. For the same reason domestic service is almost unobtainable and local authorities are unable to recruit "home helps" to care for the sick and aged in their houses.

It may well be, therefore, that the weakening of family cohesion which so many observers claim to have detected is in part a result of the trend of recent legislation. As a contribution to the study of this social problem we investigated the frequency of visiting at the infirmary, with the following result. Eighty-two per cent. of the men and 79% of the women are visited at least once a week for the first three months of their stay; thereafter the frequency of visits declines steadily, but it is not until four years have elapsed that the total of weekly visits falls to 40% for the men and 46% for the women.

Irrespective of the duration of stay of the whole sample of 714 patients, no less than 52% of the males and 68% of the females are visited by friends or relatives once a week; only 48 men (15%) and 28 women (7%) are never visited. The remainder were visited at intervals greater than a week.

In view of the depressing environment of the infirmary, of the unpleasant nature of many of the disabilities in the patients, and of the difficulties of travel, these figures show that even if natural affection has declined, as some believe, it is still a potent influence in the social life and conduct of the English. Curran *et al.* (1946) reached the same conclusion in Glasgow, and it must never be forgotten that at least 95% of the aged never go into an institution: with the help of their families and friends, or more rarely alone, they struggle on to the end.

Indisputably necessary as it was to do something to improve the material standard of life of the people, it must always be remembered that it is possible to do too much. Freedom from tyranny, from poverty and want, from the fear of unemployment, and from the hopeless despair of unattended and persistent sickness is no doubt desirable, but whether it is good to achieve it without effort on the part of the individual or his family—to have it, as it were, "laid on" by the State—is questionable, and the matter is more commonly decided by an appeal to sentiment or self-interest than by reason.

The instincts of self-protection, sustenance, and assertion imply struggle to satisfy them, and if society makes the struggle unnecessary the vitality and survival value of its individual members will diminish. Similarly, the power of the group-maintaining instincts will suffer if the provision of a home, the training of children, and the care of its disabled members are no longer the ambition of a family but the duty of a local or central authority.

In these debatable matters a decision requiring high qualities of statesmanship is necessary before new plans are made to deal with the problems of the chronic sick and infirm. The problem is simple. Shall they become the responsibility of society in large institutions or should we encourage their friends and their families to care for them whenever possible?

In the interest of social cohesion psychology and anthropology favour the second course, and so does ethics, and, while it has been the constant aim of religion and morals to extend the affections of the individual beyond the range of his personal and group relations, both agree that such extension must be based on a lively sense of responsibility for the weaker members of the family and on service to them. Aesthetics in days of realism is often confused with sentiment, but there is a beauty and a value in personal service to a crippled friend or relative that no hospital can rival. Claims of expediency and economy may be vulgar, but they are insistent, and the fact that care of the sick and disabled in their homes is cheaper than in institutions is worth emphasis.

For all these reasons, and to avert the distressing disintegration of human personality that is so common in patients who lie for years in an infirmary, it would be wiser to endeavour to preserve the sense of family responsibility and to encourage people to tend their own sick and guard the aged.

That does not mean that families should be expected to bear the whole burden. Society must help them, and the problem really hinges on the type and extent of assistance to be provided. Institutions will always be necessary, but the aim should be to reduce the demand for them, and the measures to be adopted must not conflict with the claims of human instinct or with the principles of ethics, morals, and religion.

(A list of references will appear at the end of the second lecture, which will be published in our next issue.)

A memorandum prepared by the Minister of Health's Standing Advisory Committee on Cancer and Radiotherapy and endorsed by the Central Health Services Council has just been issued for the general guidance of regional boards and boards of governors. The memorandum suggests that no recognition should be accorded to "cancer" as a specialty in itself. To secure full efficiency a cancer service should provide a single organization to serve a population of the order of two million to four million. The area served should normally, but need not necessarily, be coterminous with that of a regional hospital board. Each cancer service should have a co-ordinating committee, appointed jointly by the regional hospital board and board of governors, concerned with the allocation of work to hospitals, records, follow-up, transfer of patients, provision of equipment, and other matters. It should include representatives of the university and medical school, and should have the advice of local health authorities and of a professional and scientific subcommittee including representatives of the universities and the appropriate medical school, medical officers of health, and general practitioners. Facilities for preliminary consultation should be established at an adequate number of recognized peripheral hospitals, which should be visited regularly by specialists for consultation with the general practitioner and local staff to assist in preliminary diagnosis and for follow-up. Similar facilities should exist in all units of the organization. The co-ordinating committee should advise on the selection from among the physicians, surgeons, radiotherapists, and other specialists on the staff of hospitals in the area of those who are to form the headquarters staff of the cancer service. Treatment by radiotherapy should be under the control of specialists engaged solely in that work.

EFFECT OF LOW TEMPERATURES ON THE BITTNER VIRUS OF MOUSE CARCINOMA

BY

IDA MANN, D.Sc., F.R.C.S.

(From the Laboratories of the Imperial Cancer Research Fund, London, N.W.7)

In the *British Medical Journal* of March 26 (p. 511) appeared an Imperial Cancer Research Fund lecture by Professor W. E. Gye dealing with the propagation of mouse sarcomas by means of frozen and dried tumour tissue. The experiments described make it clear that by refrigeration and subsequent drying at a low temperature the tumour cells can be killed and an active agent liberated which is capable of starting tumours afresh, and which, judging from those of its properties so far known, is viral in nature. This holds good for both chemically induced and spontaneous sarcoma in mice, so that we can regard the virus as the continuing cause of sarcoma (i.e., the agent which is responsible for the continuing cell division), while the chemical in those tumours apparently started by it acts as the inciting cause, allowing of, or producing, the change in the virus from the latent to the active form.

This sequence of events can be closely paralleled by what is already known to be true of mammary adenocarcinoma in mice. Bittner and his co-workers in the United States have shown that these tumours have for their continuing cause a virus (the Bittner milk factor), but that this virus requires a chemical inciter (oestrin) before it can change from the latent to the active form and produce a cancer. This virus, of which the active form can be seen in the tumours with the electron microscope (Porter and Thompson, 1948) is present in the milk of lactating female mice in the latent form and enters the bodies of the young mice as they suckle, especially if the milk is drawn into the respiratory passages (Begg, 1949). Here it circulates throughout the life of the mouse, reaching every organ which has a blood supply (Woolley, Law, and Little, 1941), but because of its high tissue specificity it is capable of producing tumours only in mammary cells and then only in the long-continued presence of oestrin.

In the male mouse, mammary tubules, imperfectly developed and without secreting acini, are present over large areas of the subcutaneous tissue, but even in high cancer strains male mice do not develop mammary cancer unless they are subjected to prolonged treatment with oestrin, when tumours occur as in the females—i.e., the virus changes from the latent to the active form. Hitherto no method of obtaining the active form of the virus outside the body or apart from living tumour cells has been discovered. That obtained free in milk is naturally in the latent form and is carcinogenic only after long-continued action of oestrin.

In the present experiments, however, it has been shown that by freezing mammary carcinoma tissue at −79° C. for long periods the tumour cells are killed and the Bittner virus liberated in its active form. It is then capable of initiating new tumours in male mice without oestrin as readily as in female mice, but only when injected into mammary tissue, thus demonstrating its selective infectivity. That these tumours produced with refrigerated tissue are not transplants but are true new infections is also demonstrated by the fact that there is an increase in the percentage of tumours obtained the longer (within limits) the tissue is frozen. This suggests the slow liberation of the active virus and also perhaps the denaturing of an inhibitory substance by cold. Such inhibitory substances have already been demonstrated in the Shope papilloma and carcinoma of rabbits and in sarcomas of chickens. The present experiments were done with both sporadic mammary cancers of inbred mice and with the "63" carcinoma (Bashford's adenocarcinoma) of the hybrid M.R.C.–Hunt strain. Roughly equal numbers of males and females were used.

1. Experiments with Frozen Carcinoma Tissue Inoculated Subcutaneously in Male and Female Mice

The technique followed was that worked out in the Imperial Cancer Research Laboratory for the transmission of sarcomas. The tumour tissue was removed aseptically from the freshly killed mouse and minced finely in a Craigie mincer (Craigie, 1949). This alone should reduce its transmissibility, since mechanical disintegration of carcinomas was shown by Jensen in 1903 to reduce transplantability. It was then diluted with an equal volume of 5.3% dextrose solution in most cases and drawn up into a 5-ml. syringe, from which it was run into sterile ampoules (1 ml. in each). These were sealed, cooled rapidly to −79° C. by immersion in a solution of solid CO_2 in "cellosolve" (ethylene glycol monoethyl ether, B.D.H.), and stored in a "deep freeze" storage cabinet kept at −79° C. From this one ampoule at a time was removed as required. The contents were just thawed and, as soon as fluid, were drawn up in a small syringe and inoculated subcutaneously in the right mammary region of mice of the same strain as the tumour. The average dose was 0.05 to 0.1 ml. per mouse, which represents 0.025 to 0.05 ml. of tumour mince. It was noticed that the frozen tissue underwent a physical change, becoming more homogeneous, softer, and slightly sticky on prolonged freezing. This change also occurs in long-frozen sarcoma tissue.

The mice were then examined at intervals of three to four days and the time of definite appearance of tumours noted. Although the mice all came from high cancer lines they were used before they were old enough to develop sporadic tumours, and in all cases the tumours obtained were at the site of inoculation. It is to be remembered that when carcinomas are obtained in male mice known to carry the Bittner virus, by painting with oestrin, the tumours appear in a haphazard distribution and not at the site of painting.

Table I shows that 239 mice were inoculated and 154 tumours obtained. Tumours were obtained with equal ease in male and female mice, and the occasional omission of dextrose seemed to make no difference. The time of appearance of the tumours was related to their rate of growth; rapidly growing tumours appearing often within 10 days, and slowly growing ones being delayed from seven to 12 weeks. The stable "63" tumour appeared fairly constantly at four weeks, some mice in each batch showing it a little later or earlier than this.

If these figures are examined statistically it becomes apparent that there is a slight increase in virulence the longer the tissue is frozen. Thus, if the experiments are broken up into groups the percentages of "takes" shown in Table II are obtained. This is consistent with the gradual freeing of virus particles from an inhibitory substance, protein in nature, by continuing cold, and is not suggestive of survival of intact tumour cells. The arguments against cell survival on freezing to −79° C. in the case of sarcoma tissue have already been stated in other papers (Gye, Begg, Mann, and Craigie, 1949), but

* Technical error. † ? error. ‡ Two inoculations in one mouse.

statistical proof by numbers of successful inoculations is not so readily obtained in the case of the sarcomas, since the phenomenon of selective infectivity is not shown by them (see later), and tumours are obtained in practically 100% after freezing for any time after 15 minutes.

TABLE II

Time Frozen	No. Inoculated	No. of Tumours	Successes
15 minutes to 12 hours	72	30	41%
24 hours to 7 days ..	76	55	72%
12 to 182 days ..	91	69	75%

By application of the χ^2 test to the figures in Table I it appears that there is an enhancement of the effect of cold up to 48 hours, but this is less marked later. In these calculations the three experiments with entirely negative results have been omitted, because it is very likely that they were due to a technical error (probably thawing to too high a temperature or leaving too long after thawing before inoculating). In making calculations the readings have been arranged in 15 groups, as shown by the brackets in Table I. The value of χ^2 for the first seven readings is 12.145 with 6 degrees of freedom, which is greater than the value of χ^2 for which P is 6%. The value of χ^2 for the remaining eight readings is 2.444 with 7 degrees of freedom, which is less than the value of χ^2 for which P is 95%. This is compatible with an increase in virulence during the first 48 hours—i.e., during the death of the cells—and a stabilization later. It must be realized that the experiments were not designed for statistical analysis, and no claim is made that the statistical approach offers final proof of the increase in virulence. It does, however, afford ancillary confirmation, and suggests a rational design for future experiments. The calculations are shown in Table III.

My thanks are due to Mr. Richard Gye for these calculations.

II. Experiments in Selective Infectivity

If inbred strains of mice are used tumour tissue can be successfully grafted in both subcutaneous and intraperitoneal sites. The new tumours are simply clumps of cells of the original mouse growing in the tissues of the new host. If, however, the active form of the Bittner virus has been obtained free from living mouse cells it seems highly probable that only cells of mammary tissue can be infected, and that connective-tissue cells cannot respond to it. Since it is well known that the mammary tissue of the mouse is very widespread, and that sporadic tumours can arise almost anywhere on the surface of the

body, subcutaneous inoculation of active virus can never offer evidence for or against selective infectivity.

On the other hand, sporadic mammary cancer never arises inside the peritoneum, and yet successful intraperitoneal grafts of living tumour tissue can be easily obtained. If, therefore, frozen tumour tissue, which as we have seen readily produces subcutaneous mammary cancers, were inoculated intraperitoneally it should produce tumours if it contained living cells, and should not do so if it contained only active virus. In the experiments shown in Table IV it is obvious (by comparison with Table I) that a qualitative difference in results exists between subcutaneous and intraperitoneal inoculation of refrigerated mammary tumour. The number of failures is too high to be accounted for by any explanation other than the absence of mammary tissue in the site chosen.

The technique of intraperitoneal inoculation is difficult because of the ease with which a few cells from the surface may be carried into the deeper tissues by the needle and also because of the difficulty of avoiding contamination of the abdominal wall and subcutaneous tissues by the material in the needle during its withdrawal. This can be demonstrated in various ways. For example, the inoculum can be mixed with powdered charcoal and its position thus be rendered visible. Small particles of carbon are often found in the abdominal wall at the site of puncture. Again, microscopical examination of subcutaneous and intraperitoneal tumour grafts often reveals the presence of hair follicles which have been forced in by the grafting-needle. A further source of error is a slightly lateral inoculation. Unless the skin and the abdominal wall are pierced exactly in the midline there is always the risk of a mammary tubule being involved in the puncture.

In spite of these obvious sources of error it will be seen that out of 92 inoculations 83 were negative, and of the nine cases in which tumours were obtained six were in the abdominal wall at the site of inoculation and projected as masses of growth on both its superficial and its deep surface. These cases therefore prove nothing, since it is probable that the needle came in contact with a mammary tubule in its passage through the wall. In three of the cases intraperitoneal tumours were found apparently unconnected with any structure, but it is not possible to be certain that they were not originally attached to the parietal peritoneum at the site of needle puncture. In any case a failure to obtain growths in 90% of the intraperitoneal experiments as against a success in 75% of subcutaneous inoculations (where the chances of the virus encountering a mammary tubule are high but not even there 100%) is strongly in favour of selective infectivity of the virus as against cell survival.

Further evidence in this connexion is offered by the behaviour of refrigerated sarcoma tissue on subcutaneous and intraperitoneal inoculation. In both situations the percentage of "takes" is equally high, which suggests a qualitative difference between the carcinoma and the sarcoma virus, the one being adapted to mammary cells only, the other to connective-tissue cells, and therefore able to produce tumours in practically any situation.

Conclusions

The active form of the Bittner factor can be obtained by freezing mammary tumours at −79° C.

The activity of the refrigerated tissue increases rapidly in the first 48 hours and more slowly later.

The refrigerated tissue possesses selective infectivity for mammary tissue, thus differing qualitatively from living tumour cells, which can be grafted in any situation.

EFFECT OF REPEATED FREEZING AND THAWING ON MOUSE CARCINOMA TISSUE

BY

IDA MANN, D.Sc., F.R.C.S.

(From the Laboratories of the Imperial Cancer Research Fund, London, N.W.7)

From the experiments described in the preceding paper (p. 251) we know that storage of minced mouse carcinoma at −79° C. for long periods does not destroy, but rather enhances, the power of such tissue to start carcinomas afresh when injected into mammary tissue. From those experiments it has been concluded that such "deep freeze" storage kills the cells and renders the Bittner virus available in its active form. The present series of experiments demonstrates that while practically all carcinomas yield active material after one period of freezing (be it for 15 minutes or six months) it is not so easy to produce tumours from material which has been frozen, thawed, and refrozen. In this respect the Bittner milk virus shows itself less thermostable than the sarcoma virus, which will stand repeated freezing and thawing.

These facts were first pointed out in 1930 by Cramer,* who showed that, while a mince of the cells of mouse sarcoma 37S could be frozen in CO_2 snow, thawed, and refrozen four times in succession without much loss of activity, the "63" carcinoma was always rendered completely inactive by four such freezings. He also showed that diminution of activity occurred even in sarcoma tissue if, after freezing, the tissue was warmed up in an incubator. From this and other experiments he concluded that a thermolabile agent (stable at low temperatures) might exist in sarcomata after the cells were killed by freezing. He also pointed out that if such an agent existed also in carcinomata its presence could not be proved or disproved by failure of frozen material to produce a tumour, since the carcinoma-producing agent would be tissue-specific and could at best give rise to tumours only when in contact with mammary cells. If it were also extremely thermolabile the odds would be that repeated thawings would render it practically harmless.

At the time of Cramer's work the only carcinomas readily available for study were tumours which had been grafted from mouse to mouse for many years. Now that we have a large number of sporadic carcinomas of the R III and Strong A strains, each of them showing slight individual differences of growth rate, though all of them are associated with the "milk factor," it seems of interest to study this problem afresh. A variety of sporadic R III and Strong A tumours were tested as well as the old strain, No. 63. While Cramer's results with "63" were entirely confirmed it was found that several, though not all, of the virulent sporadic tumours would stand a succession of changes of temperature from 2° to −79° C. and back again two or three times.

Out of 24 experiments, 22 of which showed activity of the tumour agent after a single freezing, 14 showed activity after further freezing and thawing. In 13† cases tumours were produced after a second thawing, in eight also after a third thawing. In no case did a tumour inactive after the second thawing produce a tumour after the third. In no case did a "63" tumour show activity after more than one freezing and thawing. The length of time of the first freezing made no difference to the number of tumours obtained, though they appeared earlier the longer the initial freezing. This is to be expected from the enhancement of virulence by long freezing shown in the preceding paper.

It is therefore to be concluded that the active agent of mouse mammary cancer suffers progressive deterioration on repeated freezing and thawing, but that individual tumours differ in this respect, some being completely inactivated by a second thawing, others rendered progressively less active.

Technique

Each tumour was minced in a Craigie mincer. It was diluted with a small amount of saline; glucose was not

Chart showing rise in latent period at successive freezings.

added. It was sealed in ampoules containing 0.5 ml. each. These were frozen in a solution of CO_2 snow in "cellosolve" (ethylene glycol monoethyl ether, B.D.H.) to −79° C. for varying periods (from 15 minutes to 182 days). Each ampoule was then thawed, sometimes by immersion in water at 2° C., sometimes by holding in the hand. (No difference was noticed between the two methods.) If it was to be tested it was opened, the contents drawn up into a syringe, and 0.05–0.1 ml. (as in Cramer's original experiment) injected into the right mammary region of each mouse. Equal numbers of male and female mice were used, all younger than the cancer age. As stated in the preceding paper, sex is immaterial provided the injection is made in the nipple line. If the mince was to be refrozen it was dropped (after an interval of approximately five to six minutes) again into the cellosolve. Freezings other than the first were for 15 minutes to one hour. Tables A and B show the variations in the experiments and the results.

It is interesting to note that the appearance of those tumours which show infectivity after two or even three thawings is delayed with each successive thawing. Table B also demonstrates the slight heightening of activity when the same tumour is frozen for some days instead of for 15 minutes. The Chart demonstrates graphically the rise in the latent period for each tumour at successive freezings. It is therefore obvious that some activity is lost each time the tissue is thawed.

Conclusions

Repeated freezing and thawing of mouse mammary carcinoma tissue reduces its infective activity.

The apparent difference between the behaviour of sarcoma and carcinoma on repeated freezing and thawing is a quantitative and not a qualitative one.

PROPAGATION OF MOUSE CARCINOMA BY DRIED TUMOUR TISSUE

BY

IDA MANN, D.Sc., F.R.C.S.

AND

WILLIAM J. DUNN

(From the Laboratories of the Imperial Cancer Research Fund, London, N.W.7)

The propagation of mouse sarcoma, both chemically induced and sporadic, by means of tumour tissue frozen to −79° C., thawed, and then dried *in vacuo* at −15° C. has been demonstrated by Professor Gye (1949). That investigation revealed the presence of an agent, other than a living sarcoma cell, which has the properties of a virus. Since the spontaneous mammary cancers of the Strong A and R III strains of mice are known to be caused by the Bittner virus, it appeared to us desirable to try to propagate mammary cancer by the same method. The difficulties are, however, theoretically greater in the case of carcinoma than in sarcoma.

In the first place, although we know that the virus is liberated in its active form by prolonged freezing of the minced tumour, we also know that it is tissue-specific and must therefore be brought into intimate contact with mammary tissue. We know that in its active form it can infect male mammary tissue as easily as female if injected in the nipple line. But this tissue specificity in itself leads to a lower percentage of tumours in carcinoma than in sarcoma, since in the case of the sarcoma mutant of the virus any and every subcutaneous connective-tissue cell is susceptible to infection, and connective tissues are, moreover, everywhere easily accessible to an active sarcoma virus.

In the second place, experiments with serial freezing and thawing have shown that the Bittner virus is extremely thermolabile, and that many tumours will not withstand a second freezing and thawing. Since the method of drying sarcoma tissue described by Gye, Begg, Mann, and Craigie (1949) involves freezing the minced tumour in an ampoule, thawing it, transferring it to the drying-flask, and refreezing it at the beginning of the drying process, it is likely that only a few carcinomas (such as M103 and M107, described in the preceding paper at page 253) will yield active dried material by this method. We know certainly that such tumours as "63" and M91 (in the previous paper) will not withstand drying by this method. We also ascertained this

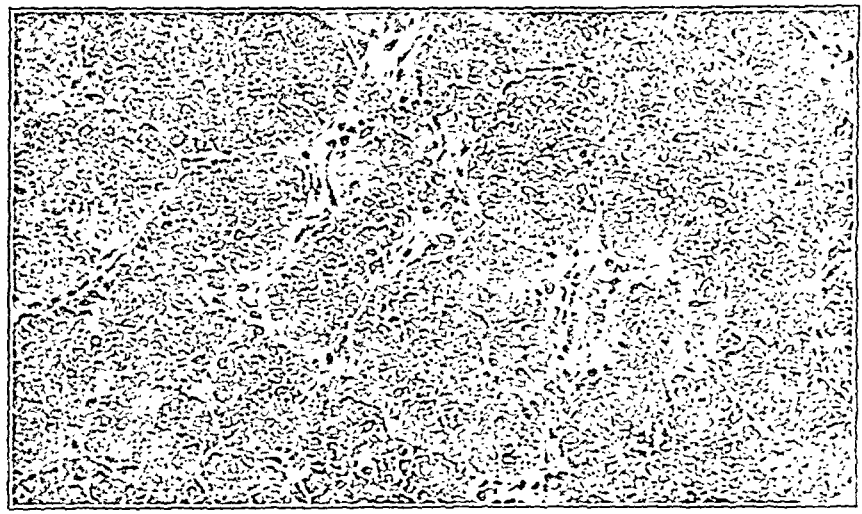

FIG. 1.—Section through the R III sporadic mammary tumour used in Experiment III (see Table).

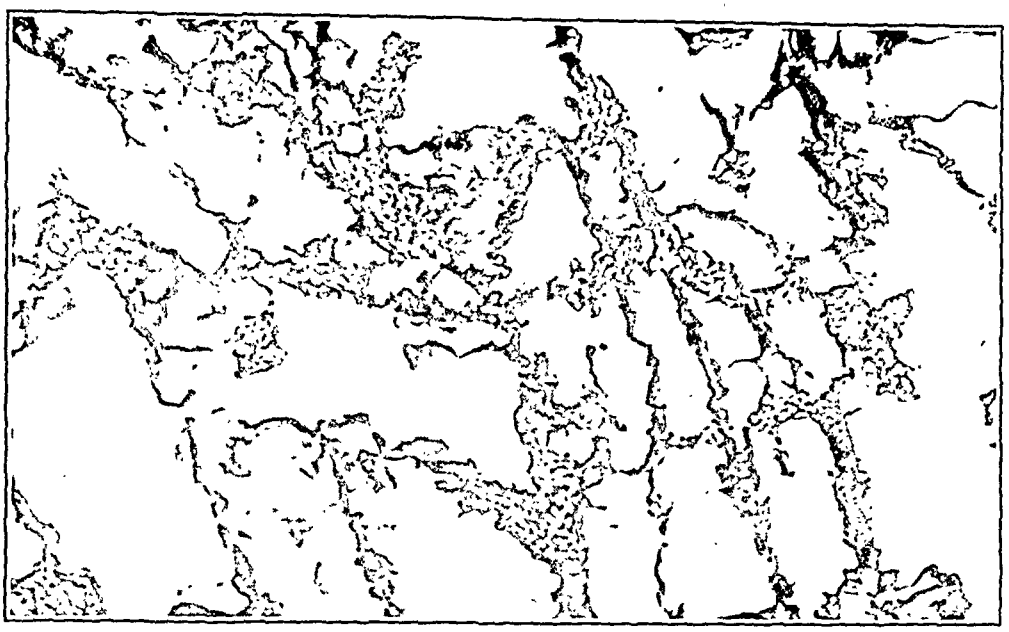

FIG. 2.—Section through the mince of the tumour shown in Fig. 1, after drying. No cellular structure is seen.

experimentally by drying "63," two C3H, and two Strong A sporadic tumours by this method. These gave uniformly negative results.

A method was therefore required which would obviate the need for thawing the material before transferring to the drying-flask. This has been done in two ways; first, by grinding up the frozen material to powder in a mortar embedded in CO_2 snow, dropping the powder into the drying-flask, also cooled below freezing-point, and sticking it to the bottom of the flask with a small amount of ice-cold 5% glucose solution, which immediately solidifies. This is necessary, since the material to be dried must be in close contact with the bottom of the drying-flask. The second and easier way is to freeze the tumour mince in the flask in which it is to be dried. For this method a tubular container was used in place of the Erlenmeyer type of flask usually employed. This made storage at −79° easier, and all that was required was to take the tube from the "deep freeze" and attach it at once to the drying apparatus. This method has the slight disadvantage that material cannot be removed from the flask for test for activity after freezing but before drying. This is easy when the first method is used.

Either method, however, gives successful results. We have succeeded in six consecutive experiments, using six different sporadic mammary cancers, in obtaining tumours from dried material in both male and female mice. The tumours appear in the nipple line at the site of injection in from four to 10 weeks. All the mice were young and well under the cancer age. Photomicrographs of sections of R III sporadic mammary tumour used and of the tumour produced by inoculation of the dried material are reproduced in Figs. 1, 2, and 3. The Table shows the results.

Technical Details

1. *Preparing the Tumours for Freezing.*—The mouse is killed with coal gas. The tumour is dissected out aseptically, a small piece fixed in Bouin's solution, the rest minced in a sterile Craigie mincer and diluted with an equal volume of 5.3% dextrose solution. If it is to be stored in ampoules, 0.5–1 ml. is placed in each by means of a syringe with a wide-bore needle. The ampoules are then frozen rapidly to −79° C. and stored in solid CO_2 for the desired time. If storage in the drying-tube is desired 1 ml. of the mince is run into the tube and by manipulation over crushed CO_2 "dry ice" is made to freeze in a thin layer spread over the sides and bottom of the tube. The tube is then stored as above.

2. *Drying.*—The frozen ampoule is removed from the storage cabinet, cracked open, and the solid mass extracted into a sterile mortar embedded in CO_2 snow. All the instruments used are sterile and chilled by keeping in test-tubes embedded in CO_2 snow. The solid mass is ground in the mortar and most of it tipped into the cold drying-flask, which stands in a vacuum jar of "cellosolve" at −15° C. Ice-cold 5% glucose solution is dropped with a pipette on to the powdered mass in the flask. This solidifies and sticks it to the bottom of the flask. The drying is then started (see Craigie (1949) for details of the apparatus). The residual moiety of the frozen material left in the mortar is now

thawed and inoculated into three mice of the appropriate strain as a control for the activity of the frozen tissue.

3. *Inoculation of Dried Material.*—When the drying is complete a small portion of the dry material is dropped into xylol and embedded direct for microscopical examination (no dehydration is of course necessary). The rest is wetted by running into the flask 2–3 ml. of a 1 in 500–1,000 neutral solution of cysteine. This produces an even emulsion, 0.05 to 0.1 ml. of which is then injected in the nipple line of each of six mice (three male and three female) of the appropriate strain. Attempts were made to improve the results by adding 33% rabbit serum saline to the cysteine and by the use of embryo extract. The latter is definitely harmful and the former of no greater value than cysteine alone, which is therefore recommended.

It must be repeated that avoidance of thawing at any time before drying is complete is essential. Experiment 82 was repeated without taking this precaution and using material known to be active, and no tumours were obtained from the dried material.

Conclusions

The active form of the Bittner virus obtained from mouse mammary cancer by freezing can be successfully dried *in vacuo* provided no thawing occurs before the material is dry.

Active dried mouse mammary cancer produces tumours in both male and female mice when injected into breast tissue.

The annual report of the National Council of Social Service (1947–8) clearly shows how independent organizations can still make a helpful contribution to public welfare by working in collaboration with the developing statutory services and, even more important, by undertaking research work in new fields. The British delegation played a notable part at the International Conference of Social Work at Atlantic City in 1948. In the same year the National Council organized with great success an International Youth Conference in London, and delegates from 25 countries took part. The activities of the Council's associated groups have also continued to expand. The National Old People's Welfare Committee, for instance, has established 17 county committees and 235 local committees. The National Assistance Act has increased the need for co-operation between voluntary agencies and Government departments. In the words of the report, "The problem is so large and increases so rapidly that it requires the combined efforts of both statutory and voluntary agencies to meet the needs. . . . The stage is set therefore for a concerted effort over the whole country for the welfare of the older members of the community." A revised and enlarged edition of the handbook *Old People's Welfare* is to be published this year.

URETHRITIS, GONOCOCCAL AND NON-SPECIFIC, TREATED BY AUREOMYCIN

BY

R. R. WILLCOX, M.B., B.S.

Physician in charge of Venereal Diseases Clinic, King Edward VII Hospital, Windsor; Senior Assistant Medical Officer, Department of Venereal Diseases, St. Mary's Hospital

AND

G. M. FINDLAY, C.B.E., M.D., Sc.D., F.R.C.P.

The treatment of non-specific urethritis has up to the present been unsatisfactory. Sulphonamides combined with urethral irrigation have in some cases been effective, but penicillin has proved of little value. Streptomycin has been shown to be successful in certain cases (Pulaski, 1947; Kane and Foley, 1947; Willcox, 1949); it is also known to be active against pleuropneumonia-like organisms both in animals and in man—a point of some interest, since there is evidence to suggest that this group of organisms may sometimes be associated with the distressing and by no means uncommon complaint of non-specific urethritis.

In the present communication the effects of "aureomycin" in non-specific urethritis are described. Pleuropneumonia-like organisms were obtained from the urethra in certain of these cases.

Aureomycin hydrochloride, dispensed in the form of capsules each containing 250 mg., can readily be given by mouth (Duggar, 1948), and oral administration is in fact probably more satisfactory than injection. Aureomycin is known to be effective against various rickettsial infections, brucellosis (Spink *et al.*, 1948; Galpine, 1949), staphylococcal and pneumococcal infections, and atypical pneumonia. Certain organisms infecting the urinary tract, such as *Aerogenes aerobacter* and *Streptococcus faecalis*, are susceptible, but *Proteus vulgaris* and *Pseudomonas pyocyanea* are resistant. Collins *et al.* (1948) and Finland *et al.* (1948) found that gonorrhoea was influenced: of 66 cases given an average of 1.3 g. over a period of 1.2 days 49 were cured, 11 were considered doubtful successes, and six were failures. Two cases of non-specific urethritis, both of which had resisted repeated courses of penicillin, sulphonamides, and streptomycin, were also successfully treated: in one, organisms of the pleuropneumonia-like group were present in the urethra before treatment. This patient was given 9 g. of aureomycin by mouth in six days: he was symptomatically improved within three days, and cultures were negative. The other patient, of whom no bacteriological details are given, received 11 g. in five days. He rapidly became asymptomatic.

Non-specific Urethritis

Four cases of non-specific urethritis were treated with aureomycin. In addition to the routine investigations undertaken in the clinic, special examinations were made both before and after treatment for the presence of pleuropneumonia-like organisms.

Case 1.—An unmarried white man aged 27 attended the clinic with a profuse purulent urethral discharge and slight dysuria of five days' duration. No gonococci were seen in the smear and no trichomonads or spirochaetes by dark-field examination. Urethral cultures revealed *Staphylococcus aureus* and diphtheroids, and pleuropneumonia-like organisms were found in smears stained with Giemsa and on culture in media containing a high proportion of serum. The urine was hazy in the first glass, and there were fullness and tenderness of the prostate, but the blood Wassermann, Kahn, and gonococcal complement-fixation tests were all negative. Treatment was deliberately withheld for two days, after which the consort was examined. She had no urethritis or cervicitis but a slight vaginitis. Coliforms were obtained on culture, and local treatment with acetarsol was prescribed.

Aureomycin in 250-mg. capsules was then administered orally to the man until a total of 2,000 mg. had been given over 60 hours. The discharge disappeared by the second day of treatment, but there was some headache and diarrhoea on the last day. When seen two days after the completion of treatment the urethral smear was free from pus, as was the prostatic bead. Ordinary urethral cultures grew only diphtheroids and *Staph. albus*, and a special examination revealed no pleuropneumonia-like organisms. The patient remained free from discharge, with a clear urine and a normal prostatic bead, while 8, 22, and 29 days later prostatic cultures grew only staphylococci.

Case 2.—A white man aged 39 who had been married for one month complained of a slight pain in the groin and a urethral discharge of five days' duration. The urethral smear revealed pus, and the urine was hazy in the first glass. The Wassermann, Kahn, and gonococcal complement-fixation tests of the blood were negative. The wife was examined, but there was no evidence of urethritis, cervicitis, or vaginitis. Her cultures showed *Staph. albus* and diphtheroids only.

Between Jan. 31 and March 14 the husband was seen on eight occasions and was given in succession 20 g. of sulphadiazine over five days, two single intramuscular injections of 300,000 units of procaine penicillin, a course of "mandamine" (two tablets four times daily for seven days), and a hexamine mixture for one week. At the end of this time the discharge was as profuse as ever and the urine was smoky, with threads in the first glass. The urethral smear showed an abundance of pus, and the culture grew *Staph. albus* and diphtheroids. Pleuropneumonia-like organisms were isolated in culture and were seen in smears stained with Giemsa. No spirochaetes or trichomonads were found by dark-field examination, and the serum tests were repeated and still found to be negative. He was given four capsules of aureomycin (1,000 g.), which were taken at intervals during 24 hours. When seen five days later there was a little urethral moisture containing a very few pus cells and the urine was quite clear, although a few threads were present. Culture of the urethra continued to show *Staph. albus*, but examinations for pleuropneumonia-like organisms were now negative. No other treatment was given and no discharge was apparent; the urine remained clear and the prostatic bead free from pus (although prostatic culture continued to show *Staph. albus*, diphtheroids, and occasionally coliforms) 10, 19, 24, 40, and 60 days after treatment. Frequent unprotected intercourse with the wife was resumed without trouble.

Case 3.—An unmarried white man aged 28 had a purulent discharge without dysuria for one week. There had been repeated exposures to one girl. The urethral smear showed an abundance of pus but no gonococci, and no trichomonads or spirochaetes were found by dark-field examination. Urethral culture grew *Staph. albus*, and pleuropneumonia-like organisms were recovered from the urethra. The consort was examined and showed no urethritis or cervicitis but a slight vaginitis. Cultures showed coliforms, diphtheroids, and *Staph. albus*. She was treated with acetarsol locally. The man was given four capsules of aureomycin within 24 hours, and when seen the following day his urethra was dry and his urine, which formerly had been hazy in the first glass, was now clear. The prostatic secretion was free from pus and the prostatic culture still grew *Staph. albus*, but no pleuropneumonia-like organisms could be recovered. When seen one week later there was a slight relapse, there being a scanty purulent discharge of one day's duration. Fresh exposure was denied. The urethral smear revealed only a moderate amount of pus cells, and, though the urine was very hazy, it cleared on the addition of a considerable amount of acetic acid, to leave a slight haziness in the first glass. The Wassermann, Kahn, and gonococcal complement-fixation serum tests were negative. He was again treated with aureomycin, being given four capsules (1,000 mg.) in 24 hours. When seen 2, 7, and 14 days later there was no discharge, and the urine was again quite clear and the prostatic bead free from pus. *Staph. albus* was grown both at the time of the relapse and again after re-treatment. A further search for pleuropneumonia-like organisms before and after the relapse was negative, and 40 days later the patient had no further symptoms.

Case 4.—An unmarried white man aged 19 had a mucopurulent urethral discharge with slight dysuria for one week. There had been an exposure in Lisbon two and a half weeks before the onset. The urethral smear and culture revealed no gonococci, but he had taken 2 g. of sulphathiazole during the previous two days. No trichomonads or spirochaetes were found by dark-field examination, and the Wassermann, Kahn, and gonococcal complement-fixation tests of the blood were negative. The urine was hazy in the first glass. He was given four capsules of aureomycin (1,000 mg.) over 24 hours, but when seen two days later the condition was unchanged. Urethral cultures from this case showed only *Staph. albus*, and pleuropneumonia-like organisms were not recovered by culture or seen in smears stained with Giemsa.

Gonorrhoea

For comparison two cases of gonorrhoea were treated.

Case 1.—An unmarried white man was first seen on Jan. 1, 1949, complaining of a urethral discharge of one week's duration and a swollen right testicle since October, 1948. The purulent urethral discharge contained an abundance of gonococci, and he was treated with a single intramuscular injection of 300,000 units of procaine penicillin. The discharge rapidly abated and the epididymitis subsided, but unfortunately his consort could not be persuaded to attend. On Jan. 21 he again showed a purulent urethral discharge containing gonococci, although he denied re-exposure. The apparent relapse was treated with a single injection of 600,000 units of procaine penicillin, to which he responded, and he was quite well when seen 7, 30, and 36 days after treatment. On March 5, following exposure one week before to the same girl, he came once more with a purulent urethral discharge containing gonococci. The urine was hazy in two glasses, and the Wassermann, Kahn, and gonococcal complement-fixation tests of the blood were negative. His consort was secured and found to be suffering from gonorrhoea, which was treated.

The man was given eight 250-mg. capsules of aureomycin hydrochloride orally over 52 hours. When seen 48 hours after the onset of treatment, and before its completion, the discharge had completely gone and the urine was absolutely clear. An absence of discharge, a clear urine, and a freedom from pus in the prostatic smear, together with a negative culture for gonococci, were found at 7, 14, 35, 42, and 49 days after treatment.

Case 2.—An unmarried white man aged 28 attended the clinic with a purulent urethral discharge and slight dysuria of four days' duration. There was also a small, slightly tender right inguinal lymph node, and there had been a contact with a stranger ten days before. Gonococci were found without difficulty in the smear and were confirmed by culture. The urine was markedly hazy in the first glass, and the Wassermann, Kahn, and gonococcal complement-fixation serum tests were negative. He

was given four capsules of aureomycin in divided doses over 20 hours (1,000 mg.). When seen two days later the discharge had gone and the urine was completely clear apart from some threads in the first glass; the inguinal adenitis had entirely subsided. The urethral smear showed no pus cells, and the culture was negative for gonococci. He did not trouble to attend again until the 26th day, when he had no discharge, his urine was clear, and his prostatic secretion was free from pus.

Discussion

The results here recorded confirm those from America, and suggest that aureomycin is a satisfactory treatment both for gonococcal urethritis and for non-specific urethritis, pleuropneumonia-like organisms disappearing rapidly from the urethral discharge.

Aureomycin has also been shown to be effective in lymphogranuloma venereum (Wright *et al.*, 1948a, 1948b) and in granuloma inguinale (Greenblatt *et al.*, 1948). In addition O'Leary *et al.* (1948) have reported that doses of 40 to 50 g. of aureomycin rapidly cleared up the clinical symptoms in two cases of syphilis with early secondary lesions: serological reactions were unaffected. This antibiotic therefore seems capable of influencing all the common venereal infections.

Summary and Conclusions

Two cases of gonococcal and four cases of non-specific urethritis have been treated by oral aureomycin. One of the gonococcal cases and one of the non-specific cases received 2,000 mg. and the remainder 1,000 mg. over 24–60 hours.

Both the gonococcal cases responded, as did three of those with non-specific urethritis. Although one of the latter relapsed, it reacted favourably to further treatment. There was one failure.

In addition to the routine tests special examinations were made for pleuropneumonia-like organisms in patients with non-specific urethritis. These organisms were recovered before treatment in three cases and after treatment in none.

Our thanks are due to Professor G. A. H. Buttle, O.B.E., in whose laboratories in the Department of Pharmacology, School of Pharmacy, the special bacteriological investigations were carried out. One of us (G.M.F.) wishes to thank the Medical Research Council for a grant towards laboratory expenses.

The effect of vaccination during pregnancy on the incidence of malformations has been studied by Greenberg and his colleagues (*Paediatrics*, 1949, **3**, 456). More than 5,000,000 people were vaccinated following the outbreak of smallpox in New York early in 1947. Among these were 4,172 women in the first three months of pregnancy. They gave birth to 68 children with malformations, an incidence of 1.63%. A control non-vaccinated group of 2,186 women in the same period of pregnancy gave birth to 30 malformed infants, an incidence of 1.37%. These studies have shown that vaccination of women in the first three months of pregnancy does not appear to have any deleterious effect on the developing embryo.

NEUROLOGICAL COMPLICATIONS OF MUMPS

BY

JAMES MACRAE, M.D., F.R.F.P.S., D.P.H.

AND

A. M. G. CAMPBELL, D.M., M.R.C.P.

(From Ham Green Hospital, Pill, near Bristol)

Hamilton (1781) first recorded cerebral manifestations associated with mumps; since then the subject, without becoming properly crystallized, has commanded medical interest as a comparative rarity.

Dopter (1910) reported that 9.8% of 1,705 cases of mumps showed meningeal symptoms, but admitted that "real" meningitis might be very rare. When Acker (1913) studied details of 30 fatal cases of cerebral mumps he considered that true meningo-encephalitis had been present. During and after the 1914–18 war French and American physicians described meningo-encephalitis complicating mumps, and details of isolated cases continue to appear in medical journals.

Coe (1945) agreed with Paddock (1932) that clinical meningitis accompanied mumps in from 0.15 to 0.5% of cases. Frankland (1941), in discussing a mumps epidemic involving 234 cases, put the occurrence of meningitis as high as 30% and reckoned that meningeal symptoms in contact cases of mumps could be presumed to be due to mumps infection. Five of Frankland's cases gave a meningeal reaction in the cerebrospinal fluid. Another epidemic of mumps, among men of the New Zealand Expeditionary Force in Japan, was noted by Laurence and McGavin (1948), who considered that out of 208 cases 60 had symptoms suggestive of meningeal involvement and six had definite meningo-encephalitis.

Ford (1937) has collected information demonstrating the widespread neurological lesions which may be expected in mumps, lesions involving almost any part of the central nervous system.

While it is generally agreed that the cerebral symptoms usually occur after the ordinary signs of mumps have shown themselves, Colomb and Mary-Mercier (1912), Bedingfield (1927), and Frankland (1941) described cases with neurological signs before there was any suspicion of mumps. Also, Howard (1919) and Frankland (1941) reported cases in which meningo-encephalitis occurred during a mumps epidemic and suggested that these were cases of mumps with the neurological signs as the only clinical manifestations.

Dopter (1910), Frankland (1941), and Lightwood (1946) tend to hold that the virus of mumps can be primarily neurotropic, and this view is given tentative authority by Harries and Mitman (1947) on experimental evidence. Similarly, Box (1946) ascribes the virus with possible neurotropic qualities.

In reviewing this considerable literature and remembering that individual cases of mumps meningo-encephalitis are still reported in some detail from time to time, we feel that a group of 14 cases occurring in a restricted area and during a short period of time merits attention.

The Present Series

With one exception all the cases developed in the Bristol area in May (1 case), June (3 cases), July (3 cases),

August (6 cases), and September, 1948 (1 case). During the same period 23 cases of anterior poliomyelitis were admitted to hospital—more than during the general epidemic period of 1947. Otherwise there was no marked prevalence of virus infections. It was noted that 18 out of 48 cases of known anterior poliomyelitis had long previously had mumps.

Since mumps is not notifiable and cases are not usually admitted to hospital, it is impossible to compute the total number of cases in the area during the time that we received these 14 cases, but hearsay evidence did not suggest even a moderate mumps epidemic. Table I gives details of the cases.

It will be seen that Cases 1, 4, 6, 12, 13, and 14 had signs of involvement of the central nervous system before there was any other indication of mumps. All the patients appeared to be alarmingly ill on admission, and the majority entered hospital under a quite justifiable diagnosis of meningitis. Four cases showed paralysis, and nystagmus was a common feature. Pyrexia on admission was constantly in the region of 102° F. (38.9° C.). Bradycardia, reported as common by French writers, was not noted. Severe frontal headache was a distinctive feature. All the patients were discharged well and without sequelae. Table II gives details of cerebrospinal fluids on admission.

In all cases the fluid pressure was raised and the general picture was that noted in other types of virus encephalitis.

The emphasis laid by Frankland (1941) on the occurrence of a purely lymphocytic reaction was not sustained; in fact, the polymorphonuclear percentages were welcomed in differentiating some of the cases from benign lymphocytic meningitis; but these polymorphonuclear findings made the differential diagnosis from tuberculous meningitis more difficult, and in view of the necessity for early treatment of this condition with streptomycin the problem is important. The recent emphasis on the lowering of the cerebrospinal fluid sugar concentration in tuberculous meningitis should be a valuable differentiating point, for the sugar concentration in mumps meningitis is not low. It is worth noting that two of our cases were admitted as cases of tuberculous meningitis for streptomycin treatment.

Most of the cases of mumps meningitis give a history of previous contact with a case of mumps, which is not always inquired about. It is of interest to note that Case 7 was that of a nurse who came in contact with Case 11 and might well have had the same strain of virus. A further contact with this nurse was a surgeon working in the same hospital, who also developed a severe meningitic reaction, coming on nine days before the appearance of orchitis. As this surgeon refused lumbar puncture we are unable to include him in this series. It does seem that this strain of virus was highly neurotropic.

These three cases bear some resemblance to the cases of mumps meningitis in twin brothers quoted by Paddock (1932). These two brothers developed typical severe meningitis with increased cellular responses in the cerebrospinal fluid, but neither case showed any parotitis. Three sisters in the same family, however, showed the typical parotid symptoms found in mumps. It would seem, therefore, that the virus can have a predilection for the nervous tissue in certain people, but it more usually reacts on the parotid.

Comment

Although it has been suggested that a cerebrospinal reaction exists in cases of orthodox mumps, and Lavergne *et al.* (1938) have even shown many instances of a cerebrospinal fluid pleocytosis in asymptomatic contacts of mumps, most commonly during the last three days of the incubation period, yet a grouping of 14 cases, such as put forward in this article, suggests the presence of an organism more than usually neurotropic. It might also suggest a population more than usually susceptible to a neurotropic virus, and this might have some bearing on the unusual prevalence of poliomyelitis during the same period.

Donohue (1941) has described perivascular demyelinization, similar to that seen in other cases of post-infective encephalitis, when he reported the pathology of a case of fulminating mumps meningo-encephalitis. Gordon (1927) experimentally produced mumps encephalomyelitis in a monkey (*M. cynomolgus*), and noted a cerebrospinal fluid reaction similar to that seen in the cases described here. He also described histological parotitis at necropsy in four cases of encephalitis lethargica (Gordon, 1913). Armstrong *et al.* (1936) similarly demonstrated the virus of choriomeningitis in the testes of experimentally infected monkeys.

There are authenticated cases of orchitis (Humphries, 1947) and pancreatitis (Box, 1946) as the only signs of mumps. We may therefore be but guessing at the tissue predilections of virus organisms. It may well happen that cases loosely described as aseptic meningitis may in reality be mumps meningo-encephalitis. If, however, after study of the other manifold manifestations of mumps it is considered that this virus infection is generalized and apt to influence any tissue—even the foetus *in utero* (Humphries, 1947)—then it is quite understandable that the central nervous system can at times be affected too, and possibly in preponderance. Thus it would no longer be necessary to postulate a neurotropic virus but rather one which settles where it will, and, depending on the speed of immunity production, the salivary glands, central nervous system, pancreas, ovaries, testicles, or pericardium may one or all produce clinical signs of virus inflammation.

Summary

The literature concerning the central nervous system manifestations of mumps is reviewed.

Fourteen cases of mumps meningo-encephalitis are presented, six of which occurred before other signs of mumps developed.

The place of the neurological signs of mumps in the picture of the disease is discussed, and it is suggested that, being a general infection, central nervous types of the disease are apt to occur more by accident than because the virus is necessarily essentially neurotropic.

LEUCOCYTE COUNTS IN THE PREVENTION OF DRUG AGRANULOCYTOSIS

BY

C. J. YOUNG, M.B., D.T.M., D.P.H.

(From the Pathological Department, Bradford Royal Infirmary)

Himsworth (1948) stated that he and Morgans (1947) had come to the conclusion that frequent blood counts for the early detection of agranulocytosis during treatment with thiouracil are worse than useless, because agranulocytosis develops like a bolt from the blue, and a normal count may impart a quite unjustifiable sense of security. This has long been known in the case of the sulphonamides, but the evidence has been generally disregarded, and leucocyte counts for purposes of prophylaxis are still considered desirable. Roberts (1948) and Hendry (1948) have drawn attention to the greatly increased demands being made on clinical pathological departments of hospitals, and leucocyte counts, requested under the mistaken impression of their value in the prevention of agranulocytosis, constitute an unnecessary and wasteful part of such demands.

I drew attention to the failure of serial leucocyte counts during sulphanilamide administration either to give warning of an impending agranulocytosis or to prevent a fatal outcome (Young, 1937). Later I collected evidence supporting this observation (Young, 1944). On the other hand, Britton and Howkins (1938) carried out leucocyte counts during 14 days of sulphonamide treatment in 50 patients, and found that the polymorphs fell during treatment in 46% of cases—in 10% to fewer than 2,000 per c.mm—but they did not observe agranulocytosis. Also Bigler *et al.* (1938) carried out counts in 33 persons during short courses of sulphonamide treatment, and concluded that sulphonamides seemed to cause depression of white blood cells even to a point at which leucopenia developed, but agranulocytosis did not occur with this depression.

It might be anticipated that leucocyte counts would be useful in the prophylaxis of agranulocytosis in two ways: (1) in preventing the occurrence of agranulocytosis, and (2) in reducing case mortality through earlier diagnosis.

Influence of Counts on the Occurrence of Agranulocytosis

It has been assumed that the detection of a drop in the leucocyte count to a leucopenic level during treatment would enable agranulocytosis to be averted by stopping administration at this stage, and it has been claimed that this has been achieved (Hohmann, 1938). Plum (1937), by administering amidopyrine to patients who had recovered from agranulocytosis due to the same drug, showed that the changes in the marrow are well established before the peripheral blood gives any warning, and that, although administration of the drug was stopped long before this warning in the blood, agranulocytosis followed. His experiments, and other evidence (Shecket and Price, 1939: Agranat *et al.*, 1939: Filler, 1941), indicate that when a leucopenia is due to an imminent agranulocytosis the latter will follow whether the drug is stopped or not. If a rise in granulocytes occurs immediately after administration ceases the condition merely represents the mild leucopenia which occurs in about 50% of persons, as demonstrated by Britton and Howkins (1938) and Bigler *et al.* (1938) with sulphonamides.

That such a leucopenia does not proceed to agranulocytosis is readily demonstrated by continuing the administration of the drug. Such a test case is the following, in which thiouracil was given for the treatment of thyrotoxicosis.

Before treatment was started the blood showed a polymorph count of 3,000 per c.mm. in a total leucocyte count of 5,600. After 14 days' treatment the count had fallen to 1,480 polymorphs in a total count of 3,900. At this stage, instead of suspending treatment, the dose of thiouracil was doubled. Four days later the counts were the same, the polymorphs being 1,587 and the total leucocytes 4,100. At the end of a further six days' treatment the polymorph count had risen to 3,538 and the total leucocytes to 6,100, restoration to the pre-treatment level having ensued in spite of the continued administration of the higher dosage.

If such a leucopenia is to be used as an indication for stopping treatment it not only seems to be an unreliable indicator but may be so misleading that it results in patients being deprived unnecessarily of the benefits of treatment.

Filler's (1941) case strikingly demonstrated the failure of leucocyte counts in the prevention of agranulocytosis. The case was one of staphylococcal septicaemia treated with sulphamethylthiazole. After the blood culture had become sterile, pyrexia was still present and drowsiness was noted for the first time. There was no leucopenia at this period, but owing to the suggestion of toxicity the drug was stopped. Six days later polymorphs had completely disappeared from the peripheral blood, so that, although treatment had ceased before there was any warning leucopenia, agranulocytosis was not prevented.

Influence of Leucocyte Counts on Mortality

Although leucocyte counts are generally misleading as indicators of impending agranulocytosis, it might be anticipated that serial counts, by bringing about cessation of the offending drug at the earliest possible moment, would lower mortality in comparison with cases in which no counts were made.

To test this assumption the available data relating to 74 cases of sulphonamide agranulocytosis were extracted from the literature and are presented in the Table.

Table Showing Leucocyte Counts and Mortality

No. of Counts:	0	1–14	1–3	4–14
No. of recovered cases	14	19	14	5
No. of fatal cases	16	25	16	9
Case mortality per cent	53	57	53	64
Observed difference per cent.	4		11	
2 × standard error of difference	23·5		32	
Significance of difference	Nil		Nil	

Two comparisons are made: first, between cases having no counts and those having one or more; secondly, between those having one to three counts and those having more than three. The latter are rather few in number, but in no group was any significant difference in case mortality demonstrated. While the data may not be sufficient to establish the absence of any influence of leucocyte counts on case mortality, they show that the assumption generally made that they will do so is not justified on the available evidence, at least in regard to the sulphonamides. Individual cases illustrate how completely they can fail. In one of my own cases (Young, 1937) treatment was stopped on the day after a count which showed no drop in polymorphs, so that even if a reduction had been demonstrated on the following day the drug would not have been stopped sooner, yet the patient died. In the case of Shecket and Price (1939) five counts in the six days preceding agranulocytosis failed to avert a fatal outcome, although the drug was stopped when the leucocytes fell from 12,500 to 8,500 per c.mm. Morgan and Detweiler (1939) described a case in which 14 counts were made during 19 days' treatment, but again death occurred. Other cases providing similar evidence are among those enumerated in the table, references to which, with individual data, are given by Young (1944).

Discussion

The evidence, both experimental and clinical, indicates that in drug agranulocytosis the condition is inaugurated in the bone marrow some time before granulopenia occurs in the peripheral blood, and the information given by the latter is too late for prophylactic purposes. Plum's (1937) experiments with amidopyrine showed that the formation of granulocytes ceased at its earliest stage, but that the marrow granulocytes already formed continued to develop and so sustained the numbers in the peripheral blood for some days after the condition had been established in the marrow.

The bone-marrow changes found in sulphonamide agranulocytosis have been variously described as absence, reduction, maturation arrest, and aplasia of neutrophil granular cells, but the term "maturation arrest" is not justified, as it has been based only on single examinations which cannot show whether the picture is static or changing. As indicated above, Plum showed that there was no maturation arrest in amidopyrine agranulocytosis.

Rubinstein (1944) made serial marrow examinations in a case of thiouracil agranulocytosis during recovery. He showed that the return to normal of the marrow preceded that of the peripheral blood, the polymorphs in the latter reaching the pre-treatment level some time between the sixth and nineteenth days after the marrow count was normal. These observations again indicate a considerable time lag between the marrow and the peripheral blood, and agree with Plum's findings with amidopyrine that marrow examination gave earlier information than did the blood.

Beck (1933) recorded that the myeloid bone marrow in agranulocytosis might be aplastic, normal, or hyperplastic, and this variability in the marrow findings has caused some confusion regarding the basis of the condition. A type of agranulocytosis occurs which is probably due to cell destruction rather than failure to produce granulocytes, but, so far as is known, this type does not seem to be produced by drugs. The finding of numerous granulocytes in the bone marrow has been reported in cases due to various drugs, including at least one due to sulphonamides (Rosenthal and Vogel, 1939). It is probably significant that this sulphonamide case was the only one to recover among those in which the marrow was examined in the series studied by Young (1944), the others all showing various degrees of aplasia.

From an examination of available data (Dameshek, 1944; Young, 1944) it seems likely that the variations reported in the marrow in drug agranulocytosis generally are due to variations in the state of marrow recovery at the time of examination. The marrow has most often been examined post mortem, and, death being as a rule due to bacterial invasion and not directly to the state of the marrow, all stages of recovery in granulocyte production may be present at the time of death. A single examination of the marrow may therefore be misleading in regard to the nature of the condition, which, when due to drugs, usually appears to be aplastic in type.

Instead of leucocyte counts during treatment with thiouracil, Himsworth *et al.* (1947) recommend that every patient should be told that if he develops a sore throat

or fever he must discontinue the drug and report to his doctor. The same procedure might be applied in the prolonged sulphonamide administration employed in rheumatism prophylaxis. For other cases of sulphonamide administration, limitation of the period of treatment to a week or ten days is probably the best method of prophylaxis, and seems to have almost eliminated agranulocytosis due to this group of drugs. Amidopyrine agranulocytosis is readily avoided, as this drug is unnecessary and should no longer be used.

Summary

No evidence has been found that serial leucocyte counts during the administration of agranulocytosis-producing drugs either prevent agranulocytosis or reduce case mortality.

The reason for this failure is found in the bone marrow, where the condition can become fully established before the peripheral blood gives any warning.

Reliance on leucocyte counts is undesirable, as they may give rise to a misguided sense of security which may prevent the adoption of more useful measures.

Leucocyte counts for purposes of prophylaxis also constitute a waste of time in clinical pathological departments of hospitals, and may mislead clinicians into stopping the administration prematurely, so unnecessarily depriving patients of the benefits of treatment.

Other methods of dealing with drug agranulocytosis are briefly mentioned.

I am indebted to Dr. J. K. Rennie for clinical data. Much of the material in this article is taken from a thesis accepted by the University of Edinburgh for the degree of M.D.

Information about the hospital services in the United States is summarized in a report published in the *Journal of the American Medical Association* (May 7, 1949, p. 23). The present bed capacity is 1,423,520, and the average daily number of patients occupying hospital beds during 1948 was 1,217,154. Between 16 and 17 million patients were admitted to hospital during the year. The greatest increase in service compared with past years was in the general hospitals. The average daily number of patients in mental hospitals was 664,399: thus nearly 55% of the occupied hospital beds were utilized for psychiatric care. The tuberculosis hospitals contained about 5% of the total hospital load. The average length of stay in general hospitals fell from 11.4 days in 1947 to 10.5 in 1948. There are now 807 hospitals approved for the training of interns and 1,140 for the training of resident physicians. The accredited schools of nursing education, which total 1,163, enrolled 100,174 student nurses in 1948.

TORSION OF NORMAL FALLOPIAN TUBE

BY

R. de SOLDENHOFF, F.R.C.S.Ed., M.R.C.O.G.

Obstetrician and Gynaecologist, Ayrshire Central Hospital

Torsion of the normal Fallopian tube when first encountered strikes one as being rare enough to warrant a little excitement. On looking at the tube and its mesentery during operative work in the abdomen it is hardly conceivable that the tube itself should undergo torsion without involving the neighbouring structure of the ovary: with its broad pedicle it would seem impossible that it could so twist on itself as to give rise to urgent symptoms.

Case Report

A 2-para aged 24 was admitted to the maternity unit of the Ayrshire Central Hospital on Dec. 7, 1947. The elder child was 2½ years and the younger 8 months. The family history showed nothing of importance. The husband was alive and well. The patient had been feeding the baby until three weeks before admission to hospital. She stopped on account of an attack of pain in the left iliac fossa and slight uterine bleeding. This was the first sign of uterine bleeding since the birth of the baby, and she was sent to hospital by her doctor as a case of threatened abortion or of subinvolution.

On admission the temperature was 99° F. (37.2° C.), pulse 124, respirations 20, B.P. 120/80 mm. Hg; blood Rh-negative; O(iv); W.R., negative; urine, N.A.D.; chest, heart, and lungs, N.A.D. On vaginal examination a small tender mass was felt behind the uterus, which was slightly enlarged, retroverted, and tender.

After admission there was no further uterine bleeding, so the differential diagnosis rested between ectopic gestation and an inflammatory condition of the tubes. During the next three days there was a slight rise in temperature, and a course of penicillin of 1,000,000 units was given. An Aschheim–Zondek test, which had been taken on admission, was now shown to be negative, and as the patient's temperature had settled she was examined under general anaesthesia. The previous findings were confirmed and the provisional diagnosis of tubal mole made.

Operation.—On Dec. 16 the abdomen was opened through a Pfannenstiel incision. A small mass surrounded by adhesions was found in the pouch of Douglas. When the adhesions were freed the mass was found to be the left tube with three clockwise twists in it. It was removed, leaving the ovary untouched, and the stump was buried in the broad ligament. Appendicectomy was performed and the abdomen closed. The patient was ambulatory by the third day and was discharged from hospital on Dec. 27, 11 days after the operation.

The specimen would at first suggest an atypical tubal pregnancy which had undergone torsion. Section showed no evidence of pregnancy, and microscopically no cells suggestive of decidua or chorionic elements could be found. This, after consideration of the patient's symptoms and history in retrospect, supported the diagnosis of simple torsion of the tube.

Discussion

The standard midwifery textbooks make no mention of this entity, but after reviewing some of the literature it was perceived that it was not really rare. Bland-Sutton (1890) reported the first case, and since then many others have been published. In the majority there has been a history of a diseased condition of the tube—hydrosalpinx, etc. Darner (1926) states torsion of the undiseased tube is less common, particularly in the virgin. French authors, in particular Regad (1933a, 1933b), have referred to a syndrome,

as they consider the condition to be common enough to be regarded as a clinical entity in the virgin. This is of course understandable. In married women there is a greater difficulty in assessing the normality of the tubes, particularly after pregnancy, and this was borne out in my case, in which the woman's last pregnancy occurred only seven months before. She had never menstruated since then and had been feeding the baby, which of course is no bar to pregnancy or pelvic infection.

Shute (1932) wrote an extensive paper on this condition, dealing with all theories of causation and its distribution in the various age groups and types of cases encountered. He found that 80% of cases occurred during the genital activity of women and the remaining 20% during puberty: 68% of the former were on the right side and in 62% the torsion was clockwise. It has been extremely difficult to separate the cases associated with tubal disease from those in the normal tube, as only 8% of specimens had had histological examinations, although one must presume that the 20% arising before puberty occurred in a normal tube. In those not associated with disease there would seem to be some connexion with the initiation of menstruation, and Davies (1925) and McEachern (1934) each cited a case similar to mine. It must be assumed that the bleeding occurring in my case was that of a commencing period.

Blum and Sayre (1937) mentioned the prevalent theories: (1) Haemodynamic (Payr), the idea being that the pulsations of the blood vessels in the mesentery of the tube can in some way initiate the torsion; (2) Sellheim's suggestion that the movements of the body and abdominal wall could be transmitted and this would initiate the torsion. This second theory is understandable when applied to a large ovarian cyst which is in contact with the abdominal wall, for any sudden violent, irregular movement of the abdominal muscles might then start a movement of the cyst to right or left, but it would hardly seem applicable to the tube, which is lying deep in the pelvis.

Anatomical malformations and physiological peristalsis are much more likely to initiate a twist. It has been suggested that drugs such as apiol may also initiate such excessive peristalsis as to start torsion. Once a twist has occurred it is easy to understand the consequent interference with circulation and the indrawing of the fimbriae which occur in acute salpingitis and ectopic pregnancy. This results in the extravasation of blood into the tube, with the formation of a small pedunculated mass which may undergo further torsion.

Such a sequence of events will give rise to all the clinical symptoms seen in the case reported, and suggests the erroneous diagnosis of ectopic pregnancy or salpingitis.

Unless this occurs in the pubescent girl it is, to my mind, impossible to recognize a definite syndrome which will identify torsion of the normal Fallopian tube, particularly as it must be assumed that the latter cases are virginal and difficult to examine. The urgency for operation in these cases is not great; cases have been described in which the distal portion of the tube has actually been amputated by the torsion and a free tubal mass has been removed some considerable time—even years—after what must have been the original crisis.

AN OUTBREAK OF FOOD-POISONING IN BROMYARD DISTRICT

BY

M. J. PLEYDELL, M.D., D.P.H.

Medical Officer of Health for North Herefordshire

On Friday, Nov. 5, 1948, a number of people left Bromyard by coach to attend the evening performance of a play in Birmingham. They arrived early, and 14 persons, so far as is known, entered a near-by restaurant and had a meal consisting of cold beef sandwiches and coffee or alcoholic refreshment. The beef in the sandwiches was described by different patients as being "undercooked," "overcooked," "dark-looking, stringy, and tough."

Of these 14 persons, 11 were taken ill on Nov. 6 and one on the 7th, the incubation period varying from 16 to 36 hours. The presenting symptoms were malaise, lassitude, severe frontal headache, aching in the limbs and back, fever, shivering, abdominal pains, diarrhoea, and in some cases nausea and vomiting. One patient collapsed while attending a memorial service on Nov. 6. Photophobia and tenderness of the eyeballs were complained of by four patients, and one patient stated that he had had puffiness round the eyes.

The severity of the attack varied considerably: from headache and abdominal discomfort, with mild pyrexia only, to complete incapacitation with pyrexia of 102–104° F. (38.9–40° C.) at the onset, associated with extreme diarrhoea and blood in the stools. The duration of the attack extended over a period of two to three days in the mildest case; whereas in the most severe cases, although the acute phase of the illness had passed off within seven days, residual lassitude, anorexia, and minor recurrences of the headache and abdominal symptoms persisted for two to three weeks.

Two of the persons who ate the beef sandwiches suffered only from slight headache and malaise on the following day. A specimen of faeces from one of these persons gave a negative result on culture; no specimen could be obtained from the other person. It is of interest to note that, of those persons who took alcoholic refreshment, these were the only people who had *two* glasses of either gin or sherry with their sandwiches.

Investigations in Bromyard.—Specimens of faeces obtained from the 12 persons who were taken ill yielded salmonellae on culture, which were later identified as *Salmonella bovis morbificans.*

Investigation at the Restaurant, Birmingham.—(*a*) Bacteriological examination of specimens of faeces from the eight members of the staff at the restaurant showed that four persons were excreting *Salm. bovis morbificans.* Two of these four had not been ill, while the other two had had symptoms of enteritis after Nov. 5. (*b*) Bacteriological examination of rat droppings in the restaurant revealed the presence of *Salm. bovis morbificans.* (*c*) Bacteriological examination of the rat-poison which was being used in the restaurant showed the presence of *Salm. enteritidis* (Gaertner).

Discussion

These findings indicate that in all probability there was an epidemic of gastro-enteritis due to *Salm. bovis morbificans* affecting the rodent population in the vicinity of the restaurant at Birmingham, and that unprotected food had been contaminated by the infected rodents. The beef had

been cooked and served hot for lunch, then left on an open dish in the basement kitchen for eight hours before being served as sandwiches to the Bromyard party. It is presumed that the contamination occurred during this interval. Although the rat-poison used in the restaurant was not the vehicle for the spread of the infection, the risks incurred by using such a poison are obvious; and, in view of the fact that methods of food production and storage in hotels, restaurants, and cafés are seldom satisfactory, the continued use of such poisons in these places is a danger to the public health and should be prohibited.

The patients affected in the outbreak were treated symptomatically for the first week of the infection. Thereafter they were all given a course of sulphaguanidine, the dosage varying from 3 to 4 g. by mouth four-hourly by day for four days. Of the 12 patients thus treated, four complained of symptoms of intolerance, and the dosage was accordingly reduced, and in one case the course was terminated. Specimens of stools were taken from each of the affected persons until three consecutive negative specimens had been obtained, the patient then being considered free from infection. These specimens were taken twice a week for the first four weeks and thereafter once a week.

On account of the irregular intervals between the collection of specimens of stools and the small numbers involved, no relation of statistical significance can be shown between the duration of the infective period and the sex of the person affected. It is of interest, however, to note that the average period of duration of infection (i.e., the time from the onset of clinical symptoms to the date when the first of the three consecutive negative stools was obtained) was 24.4 days for the seven men affected and 47.6 days for the five women. The figures are as follows:

Period of Duration of Infection

Males	Females
23 days	39 days
20 ,,	44 ,,
30 ,,	67 ,,
23 ,,	30 ,,
20 ,,	58 ,,
32 ,,	
23 ,,	
Mean, 24·4 days	Mean, 47·6 days

If from these figures are subtracted those relating to the persons who did not receive a full course of sulphaguanidine, then the mean periods of duration of infection are: males, 26.2 days; females, 54.7 days. Thus it seems unlikely that the period of infection was influenced by the sulphaguanidine.

The five female patients and one of the male patients prepared food for consumption in their households. These persons were given instruction in personal hygiene and care in the handling of food. It is satisfactory to note that no secondary cases resulted from this outbreak.

Summary

A brief description is given of an outbreak of food-poisoning in Bromyard district due to infection with *Salm. bovis morbificans*.

Investigations revealed that the infection originated from the consumption of beef sandwiches in a Birmingham restaurant, and that the sandwiches were probably contaminated by infected rodents.

The danger of using rat-poisons incorporating salmonella organisms, especially in food premises, is noted.

The duration of infection in the female patients was approximately twice that in the males.

The evidence from this outbreak suggests that infection with *Salm. bovis morbificans* does not respond to sulphaguanidine therapy.

I would like to express my appreciation of the co-operation and help given by the staff of the Public Health Department and the City Laboratory at Birmingham, and the staff of the Public Health Laboratory at Hereford.

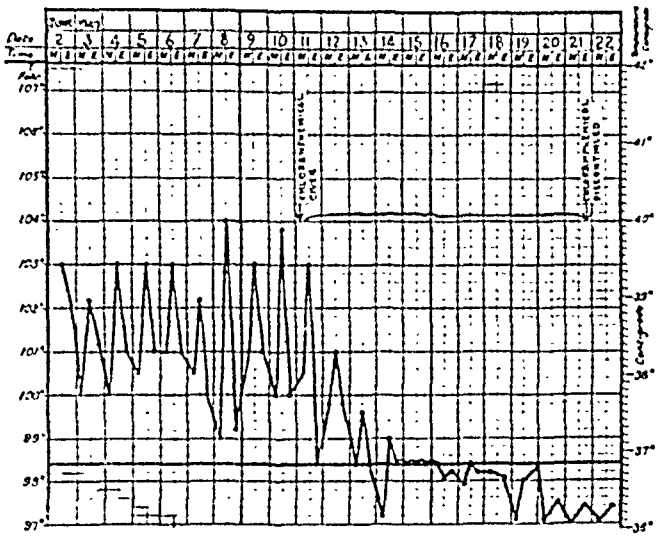
Medical Memoranda

A Case of Undulant Fever Treated by Chloramphenicol

The treatment of undulant fever has until recently been unreliable and unsatisfactory. Methods advocated have included the joint use of sulphonamides and blood transfusion (Holmes and Hughes, 1948; further recommended by Romer, 1949), and the use of "aureomycin" (Galpine, 1949); whilst the American Department of Clinical Investigation of Messrs. Parke, Davis, and Co. claim that six patients with active brucella infection responded rapidly within an average of 2–4 days to oral administration of chloramphenicol ("chloromycetin"; Parke, Davis, and Co., Technical Reference No. 1183, p. 2). This claim was so striking that one of us (T.V.C.) decided to attempt treatment of the next case of acute undulant fever met with in this area, where the infection is not uncommon. Compared with the larger towns and cities, the volume of milk consumed in this district not heat-treated is considerable, and contagious abortion in cattle is widespread.

The case of undulant fever described below responded immediately to oral administration of chloramphenicol The results seem so good that the method deserves a wider trial. No serious complication was encountered.

CASE REPORT



The patient, a man aged 50, was first seen on June 2, 1949; he gave a history of having felt vaguely unwell for the past three to four weeks. Two days previously his afternoon temperature was 103° F. (39.4° C.). The main symptoms were lassitude, sweating, anorexia, constipation, insomnia, pains in bones of back and limbs, and retro-ocular headache. The symptoms were worse in the afternoons No special physical signs were elicited. (The patient had lived in India for many years, but had been at home and healthy since 1947.) During the next seven days his temperature varied between 100° and 104° F. (37.8° and 40° C.), being usually highest in the afternoon. No localizing symptoms or signs developed.

On June 8 blood was taken for the Widal test, and gave a positive reaction up to 1 in 5,000 against *Brucella abortus* and *Br. melitensis* 1 in 1,250, trace 1 in 2,500. There were also reactions to *Salmonella typhi* H 1 in 125, *S. paratyphi* AH 1 in 50, trace 1 in 125, *S. paratyphi* BH 1 in 125, and N'S Composite Salm. 1 in 125, explained by multiple T.A.B. inoculations in the past. The Vi test was negative. A blood count taken at the same time revealed: haemoglobin, 80% (11.84 g.); red cells, 4,300,000; colour index, 0.93; leucocytes, 5,600 (neutrophil polymorphs 68%, monocytes 7.5%, lymphocytes 24.5%); reticulocytes, 1%.

Blood cultures taken on June 11 failed to yield any positive results, although development of brucella was encouraged by employing liver-infusion media and incubation in a jar containing 5–10% carbon dioxide. Blood-film tests excluded malarial infection.

At this point it was decided that the evidence warranted a trial of chloramphenicol. Treatment was therefore started on June 11. The initial dose was 5 g. (approximately 60 mg. per kg. of body weight), followed up by 0.25 g. every three hours for seven days after the temperature had settled (see Chart)—

total, 27 g. by mouth. Within 24 hours of starting treatment there was definite subjective improvement, which was maintained. The temperature had settled by the fourth day, and has remained normal up to the present time (July 22). On the first two nights the patient showed mild urticarial skin lesions, and for a few hours there was severe pain in the splenic area, but the spleen did not become palpable. The patient is heavily

Temperature chart of the case.

built, and a moderate enlargement of the spleen could easily go undetected. He also had an unpleasant taste in the mouth after taking the drug, particularly if the 0.25-g. dose was exceeded. We had given instructions that if, in error, a dose were missed during the night the succeeding dose should be increased in compensation. At the end of treatment the patient was easily tired, but otherwise he felt well. Convalescence proceeded uneventfully, and he now seems fit.

COMMENT

This case is described because the treatment seems free from risk and can be carried out at the patient's home, whereas any method employing blood transfusion implies admission to hospital and exposure to the hazards of transfusion. We appreciate that our diagnosis is based on a reasonable supposition (agglutination reaction) rather than on the absolute proof which would be given by a positive blood culture. It is known, however, that in only a small proportion of cases of undulant fever due to *Brucella abortus*, estimated at 10-20% (Topley and Wilson, 1945), can a bacteriaemia be demonstrated. Inspection of the temperature chart shows a fall in temperature exactly coincident with the administration of chloramphenicol. At the present time this method of treatment is not cheap, as 27 g. of the substance costs £30 12s., less 33⅓% discount to institutions, plus £6 16s. 1½d. purchase tax—a net total of £27 4s. 1½d. The makers inform us that negotiations are proceeding to eliminate purchase tax—an imposition which seems illogical, especially if distribution of the amounts available is restricted to definite prescriptions and specific infections.

Sensitivity to Codeine

The following case is recorded because of the rarity of reactions to codeine in spite of its common use and because of the resemblance of the rash to that of scarlet fever.

CASE REPORT

The patient, a woman aged 24 suffering from pulmonary tuberculosis, stated that one night she had been given two "veganin" tablets (containing ¼ gr. (22 mg.) of codeine phosphate) for headache. Next morning she developed an irritation of the whole body and later in the day "a red rash" appeared. On the following day the rash had faded and the irritation had subsided. She also stated that a similar reaction had followed a single dose of 1 dr. (4 g.) of syrup of codeine phosphate (codeine content, 16.2 mg.).

In order to demonstrate the specificity of the reaction, and to study the rash, several months later she was given a test dose of ¼ gr. (32.5 mg.) of codeine phosphate at midday. At 5 p.m. she developed irritation of the neck and chest, which rapidly involved the whole trunk and limbs. The irritation was followed by a macular rash, which soon coalesced to give a scarlatiniform appearance. The rash was most prominent on the front of the chest, the abdomen, and lower limbs, but the pruritus was not confined to the area involved by the rash. Both the rash and the irritation were less marked the next day, and during the following day both had disappeared; the irritation, however, remained some hours after the rash had gone.

At no time was there any lesion in the mouth, the patient felt well, and there was no febrile disturbance. Slight desquamation occurred over the lower face only. A blood count at the height of the reaction showed 259 eosinophils per c.mm.

COMMENT

In spite of its widespread use very few cases of sensitivity to codeine have been recorded. Indeed, Seidmann (1943) says that his is the tenth case to be reported.

Scheer and Keil (1934) reviewed the literature and added a further case following 1 gr. (65 mg.) of codeine phosphate. They point out that antibodies cannot be demonstrated by the direct Prausnitz-Küstner method, since codeine itself normally produces an erythemato-urticarial reaction with pseudopod formation when injected intradermally. Using a modified P.-K. technique (serum locally and codeine by mouth), they were unable to demonstrate antibodies in the serum. Scheer and Keil describe the original appearance of the rash as follicular, later taking on a generalized erythematous appearance by coalescence of the broad zone of erythema surrounding the individual follicles. They produced a positive skin-patch reaction with codeine phosphate solution (1 gr. to the ounce), while a similar test with a solution of morphine sulphate was negative, indicating a specific hypersensitivity to codeine, which is all the more significant since the latter differs from morphine only in having a methyl group.

The constant feature of the recorded cases is the pruritus followed by an erythematous rash, the early phase of which may present as macular or follicular. Usually there are no symptoms apart from the irritation. In Seidmann's case, however, weakness, fatigue, headache, nausea, and redness of the mouth and throat occurred a few hours after ingestion of 15 mg. of codeine phosphate. There was an eosinophilia of 1,080 per c.mm—a finding also recorded by Dittrich (1926). Desquamation has been reported in a few of the cases.

Reviews

FORENSIC MEDICINE

Médecine légale judiciaire. By C. Simonin. Second edition. (Pp. 819; 313 figures; paper cover, 1,100 francs; bound, 1,300 francs.) Paris: Librairie Maloine. 1947.

Psykopatibegreppets bankrutt (Bankruptcy of the Concept of Psychopathy). *By Bo Gerle. (Pp. 43; paper cover, 3 kronen; in* Swedish.) Lund: Gleerupska Univ.-Bokhandeln. 1947.

The contacts of law and medicine are now so many and various that forensic medicine has split up into a group of specialties, each calling for special training and experience. It is therefore far from easy for one author to cover the whole field; this is the task assumed by Professor Simonin, of Strasbourg, and he has performed it remarkably well. His book is the first of two volumes, and consists of massive chapters on medicine and justice and the medico-legal aspects of injury, sex, poisons, death, identification, and psychiatry; these are the topics covered by the term "*judiciaire*," social medicine and medical ethics being reserved for discussion in the second volume.

The first chapter contains an excellent sketch of the history of criminology and valuable discussions on juvenile delinquency and malingering. The section on injuries includes comment on cruelty to children, the assessment of disability, and post-traumatic disorders. The chapter on sex deals fully with the whole subject, including perversions, sterilization, abortion, marriage, pregnancy, and paternity. Much information about industrial toxicology is found in the article on poisons; those on death, identification, and psychiatry follow the usual lines.

The handling of so vast a subject might excusably have been purely technical, but the approach is, in fact, philosophical, and Professor Simonin does not conceal his strong moral convictions.

The outstanding features of the work are the author's constant preoccupation with the prevention of crime, and the excellence of the clinical descriptions which abound throughout the book and could be read with pleasure and profit by any medical man. The volume will be useful to a wide variety of specialists, and teachers of forensic medicine outside France will find in it ideas worth incorporating in their own courses of instruction. Reference to any topic is unusually easy because of a good index, a detailed table of contents, the division of the text by many cross-headings, and the free use of small type for matters of detail. The text is elucidated by many drawings, the work of the artists E. Huber and A. Collinet.

Dr. Bo Gerle is a *Dozent* in forensic psychiatry in Lund University and head of the forensic department of St. Lars Sjukhus, a large mental hospital near Lund. His book, a revised and enlarged version of a course of lectures attended by doctors, lawyers, and humanists, discusses the origin and development of the concept of psychopathy, the "psychiatry without psychopathy" of Sjöbring, and the consequences of a modified conception of psychopathy.

The first half of the book is a historical and critical study of the term psychopathy, whose current meaning is "non-intellectual deficiencies making the social adjustment of an individual difficult or impossible." The development of the concept is traced from Pinel's *manie sans délire* and Esquirol's monomania, through Platner's *amentia occulta*, Pritchard's moral insanity, and corresponding ideas of many later students, including Kraepelin, Lombroso, Freud, and Henderson and Gillespie. The conclusion drawn is that the concept of psychopathy includes a variety of unrelated conditions, which Gerle distinguishes, on the basis of Sjöbring's theories, as hypophrenia (post-infective tiredness and apathy), schizophrenia, and ixophrenia (an epileptoid state). The remainder of the book is a discussion of the legal, therapeutic, and educational implications of these concepts. It remains to be seen whether these ideas will be any more durable than their predecessors, and it is important, as the author says, to approach each patient as an individual.

Gerle stoutly defends the unity of personality and the view that a highly developed intellect may be powerless to control serious affective deficiency. This at once raises the question of criminal responsibility and challenges current legal opinion; the question merits full discussion in a separate paper, and Gerle is obviously well qualified to write it. He concludes with a plea for more thorough training in psychiatry for medical students to enable them, as doctors, to deal competently with the various types of psychical abnormality.

Gerle has a limpid style, and if he chose to write in English he would have a wide circle of readers, both medical and legal. Readers of his book would have been assisted by the use of cross-headings and the addition of a summary of the chief conclusions.

RAYMOND WHITEHEAD.

PHYSIOLOGY OF FLYING

Aviation Medicine in its Preventive Aspects. By John F. Fulton, O.B.E., M.D., D.Sc. (Pp. 174; illustrated. 12s. 6d.) London: Geoffrey Cumberlege (Oxford University Press). 1948.

This is a historical survey of the more important researches and developments in altitude or decompression sickness, the physiological problems of pressurized aircraft cabins, the effects of acceleration on man, and safety in flight. It concentrates on the period 1939 to 1946. Experiments to secure impartial data on the respiratory and circulatory changes which occur during acclimatization to the lowered partial pressure of oxygen at altitudes between 23,000 to 29,000 feet (7,000 to 9,000 m.) are described in some detail. This investigation, named "Operation Everest," was carried out at the United States Naval Air Station in Pensacola, Florida. For this purpose four young adults lived for five weeks in a low-pressure chamber fitted with an air-lock, so that observers could enter to make observations and take appropriate samples without being subjected to anoxia. The results showed that acclimatization consists of a series of integrated adaptations to restore the oxygen pressure of the tissues to the normal sea-level value.

Researches in decompression sickness are reviewed, from Leonard Hill's work on caisson sickness in divers in 1912 to those in connexion with aviation, especially during the various phases of the recent war. There is a good description of bubble formation in the blood and tissues of animals and man in relation to "bends," and of such underlying factors as gas tension, hydrostatic pressure, surface tension, and gas nuclei. The practical results of these researches are outlined. The technique is given of the pre-selection test to assess suitability for high altitude operations, and is followed by an account of the prevention or mitigation of "bends" by pre-oxygenation to displace dissolved nitrogen before ascent and by limitation of muscular movements during flight to lessen the formation of bubbles in the blood vessels.

The main physiological problems discussed in connexion with pressurized aircraft concern ventilation and explosive decompression. Little information is given as regards the former, but the section on explosive decompression is reasonably full and valuable. Reference is made to the experiment which proved that no perceptible harm is caused to a fit man by explosive decompression, provided an adequate supply of oxygen is immediately available or a rapid descent made to non-oxygen-requiring altitudes. Survival times for explosive decompression at various altitudes up to 75,000 feet (22,500 m.) are given, as well as the time of useful consciousness without oxygen. These figures have proved of great value to aircraft designers and engineers, who have to provide for emergencies while avoiding weight penalties in the form of unnecessary equipment.

The section on the effects of acceleration is limited to a consideration of centrifugal forces which occur in aerobatics. Due reference is made to the R.A.F. researches, begun in 1939, in an aircraft fitted up as a flying laboratory, with a cine-camera to record the effects of high acceleration under

conditions of aerial combat, the results of which enabled suitable countermeasures to be devised. Then follows a description of centrifugal machines used by the Canadians, Australians, and Americans, on which much fundamental research was done. The results obtained added considerably to our knowledge of the effects of centrifugal forces on man, and culminated in the development of anti-gravity suits, both of the hydraulic and air-pressure types. It is claimed that these suits did much to give Allied fighter pilots ascendancy over the enemy.

The final chapter discusses briefly the problems of safety in flight, including a study of the effects of forces of deceleration on man as demonstrated in aircraft crashes and non-fatal suicidal leaps. The design of aircraft to provide increased safety is considered, and the practical value of seat belts, safety harness, stressing of seats, backward-facing seats, and "ditching drill" are assessed.

H. E. WHITTINGHAM.

A DIGEST OF GYNAECOLOGY

A Pocket Gynaecology. By S. G. Clayton, M.D., M.S., F.R.C.S., M.R.C.O.G. (Pp. 111. 7s. 6d.) London: J. and A. Churchill, Ltd. 1948.

This is the age of digests. As members of the general public we persuade ourselves that we have no time for serious reading and too often turn to the small monthly magazine that feeds us with tasty morsels from current literature. As doctors we receive the weekly journals but too often do not trouble to read them. If we are specialists we view with dismay the monthly publications that pile up on our desks, and frequently console ourselves with the thought that a year book, a survey, or an abstract journal will soon come to hand to spare us the effort of reading the literature as it is intended to be read. If this is our weakness we cannot criticize the harassed medical student in his struggle to keep abreast of the ever-increasing medical curriculum, or deny him the help that a condensed textbook may give. But in both cases the danger is the same. Is the summary or review to be used as a genuine refresher or is it to be the means of escape from serious reading—the pander to laziness?

These thoughts are aroused by Dr. Clayton's book. As a condensed account of gynaecology this is an excellent production, and the considerable amount of up-to-date information presented in small space reflects much credit on the author and publishers alike. But whether the medical student will benefit by turning from his well-known textbook to a new "cram" book during his period of final revision is a matter on which I, for one, have serious doubt.

The usual gynaecological subjects are set out in orthodox fashion in 109 small pages of text. Anatomy, physiology, embryology, and pathology all receive due notice. The two final chapters deserve special attention—one is on gynaecological symptoms and the other on special gynaecological treatment, including a brief account of drugs and endocrine preparations, of *x* rays and radium, of gynaecological operations, and even of contraception. A few necessary illustrations are included.

The preface states that there is "economy of words." This is certainly true, even to the extent of the omission of verbs from many sentences. The text is generally well corrected; but there are a few slips, such as an obvious error of spelling on page 3 and the occasional use of a singular verb with a plural subject. In criticism of the subject matter it may be questioned whether it is not misleading to speak of "slight fever" as being a symptom experienced by normal women during menstruation. Condylomata acuminata are not necessarily gonococcal in origin, nor do they appear "after a few days." Stilboestrol in doses as large as 5 mg. daily is fairly certain to cause nausea and depression in a post-menopausal woman. These are minor criticisms in an otherwise excellent, if very condensed, presentation of orthodox gynaecological teaching. The book is exactly what it claims to be: it is a pocket gynaecology, and a remarkably good one at that.

J. CHASSAR MOIR.

GUIDE TO TREATMENT

Obstetrics and Gynaecology. By Beatrice M. Willmott Dobbie, M.A., M.B., F.R.C.S., D.M.R.E. (Pp. 358; 23 illustrations. 20s.) London: H. K. Lewis and Co. 1948.

Textbooks of obstetrics and gynaecology abound in British medical literature; it may be asked, therefore, whether there is a place for further works on this subject. Miss Dobbie's new book does not attempt to cover the same ground as the usual textbooks, but rather to provide a simple guide to practical treatment. It is addressed primarily to the general practitioner, and fulfils admirably the needs of the busy doctor who requires a handy work of reference or who wishes to refresh and bring up to date his knowledge. Simplicity of expression and sound common sense, the keynotes of this book, make it thoroughly readable.

The general layout of the work is good, and the advice it contains is generally excellent. Criticism is thus confined to a few details. The dose of ergometrine by intravenous injection should not exceed 0.25 mg., and 0.125 mg. is often sufficient. Administration of 0.5 mg., as recommended, is likely to cause symptoms. Contradictory advice is given concerning the treatment of cervicitis. In the chapter on post-natal care (p. 205) it is stated that cauterization can be carried out in the out-patient department, while cauterization under anaesthesia is recommended in the section on gynaecology (p. 292). Most cases of cervicitis can in fact be treated as out-patients, thus obviating the need for hospitalization or general anaesthesia. The section on the toxaemias of pregnancy is sketchy and inadequate. More precise advice is needed on the normal level of blood pressure, and a great deal more detail should have been included on the management of cases of essential hypertension in pregnancy and of pre-eclamptic toxaemia. The illustrations are adequate, though some appear unfinished in comparison with those appearing in other books.

The psychological aspects of obstetrics and gynaecology are not neglected, and the sections "Telling the Patient" are especially important. Miss Dobbie shows her wide experience in this book, which, though containing little new or original, fulfils the purposes for which it is intended and will thus prove a valuable addition to current medical literature.

JOSEPHINE BARNES.

SURGICAL SUMMARY

Handbook of Surgery. By Eric C. Mekie, M.B., Ch.B., F.R.C.S.Ed., F.I.C.S., and Ian MacKenzie, M.B.E., M.B., Ch.B., F.R.C.S.Ed. With foreword by the late Sir John Fraser, Bart. Second edition. (Pp. 764; illustrated. £1.) Edinburgh: E. and S. Livingstone. 1949.

A second edition of this book (which first appeared in 1936) has Mr. Ian MacKenzie, now of Newcastle-upon-Tyne, as joint author. There has been considerable revision, but, although there are 764 pages, perhaps rather many for a handbook, there are only 29 figures. These are good, but so much text unrelieved by diagrams or figures is inclined to make reading dull, and the criticism of the first edition remains—that more line drawings interspersed through the print would add considerably to the attraction of this otherwise excellent student's guide. Fig. 11, p. 308, is inaccurate in view of recent knowledge of root distribution, and I could find no mention of either the costo-clavicular or scalenus syndromes, each of which is of frequent occurrence, whereas arthrogryposis multiplex congenita (p. 594) is less common so far as the student is concerned. There is an account of cervical rib in which it is stated that Hudson (no initials, no reference) showed that the vessels and nerves can be compressed between the free end of a cervical rib and the anterior scalene muscle, and that the radial pulse is diminished on the affected side but becomes normal in volume when the arm is elevated above the shoulder (p. 212). This is not in accord with our experience, which is the reverse. The statement on page 299 that the majority of intradural extramedullary spinal tumours are meningiomas is not accurate, as the neurinoma is commoner.

These are minor criticisms of what is essentially a sound text in which for the most part the matter is well balanced.

The book may be described as an excellent summary of the teaching of the Scottish school of surgery and a sound guide for the student of the subject. Like most post-war articles the price has increased, in this case from 12s. 6d. to £1.

LAMBERT ROGERS.

ADOLESCENCE

Adolescence. Its Social Psychology. By C. M. Fleming, M.A., Ed.B., Ph.D., F.B.Ps.S. The International Library of Sociology and Social Reconstruction. (Pp. 261. 16s.) London: Routledge and Kegan Paul 1948.

This is an important and valuable book. It sums up recent research on the physiology and psychology of adolescence, as well as its educational and social aspects. This recent work has tended to upset several preconceived ideas, most of them dating from Stanley Hall's generalizations, which have been too readily accepted both by teachers and psychologists.

The book points out the wide variations of the normal personality and stresses the importance of the individual's fundamental needs. Considerable attention has in the past been placed on innate dispositions and instincts, and considerable variations in the strength of these in different individuals has been postulated. A more practical attitude may be to think more in terms of the needs of the individual, founded no doubt on the relative frustration and gratification of instincts. The author points out how the failure to find gratification of the needs in one generation may be reflected in the behaviour of the next, and how difficulty of adjustment and social misbehaviour may thus follow through several generations.

Delinquency is an expression of distress, and this distress is due to failure to achieve the fundamental needs, which are listed as love, security, new experience, recognition, acceptance, respect, and success. The dignity and individuality of the child must be recognized and respected. Growth, both mental and physical, is not a smooth process, and may be influenced by environmental factors operating at any particular time even more than by innate capacities. If this is so, it is not easy for educationists to answer the questions about which they would so much like to be definite—namely, what are the difficulties and therefore the requirements of any group of children at different stages of their development? How can future success in different activities be predicted from present performances? In other words, a cross-sectional observation, such as an intelligence test at a particular age, is not so reliable in foretelling the future development of the child as many people would like to believe. Ultimate capacity may be more influenced by limitations of experience, both social and educational, than by innate ability. The way all sorts of types of young men and women have learnt and adapted themselves to quite unfamiliar trades in the relatively short period given to training for modern technical warfare illustrates this. Young people require not only intellectual food but the influence of the right sort of group of their peers, as well as guidance by those more experienced than themselves in formulating a philosophy of life which should be a map of how they may live.

Vocational guidance is of little use if founded on single interviews, but it should be based on long-term observation of the young person. Means must therefore be found to obtain and record such observation by several persons if our youth are to be helped as they deserve. Doctors, teachers, sociologists, and psychologists will all find much in Dr. Fleming's book to stimulate thought. Presented as it is, without prejudice or bias, it is to be highly recommended.

R. G. GORDON.

Review of Dentistry for State Board Examinations, by Vincent R. Trapozzano, D.D.S., F.A.D.P. (pp. 661; 32s. 6d.; London: W. B. Saunders Co.), is a book in which dental surgery becomes a series of quick questions and snappy answers. It may possibly be useful to the student preparing for a *viva voce* examination, provided that the examiner asks the correct questions, or may even be more useful to the examiner to provide him with questions that he should ask and the reply that he should automatically be given.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Coronary Artery Disease. By E. P. Boas, M.D. (Pp. 399. No price.) London: H. K. Lewis. 1949.

A VIRUS IN MOUSE CANCERS?

In March of this year Professor Gye reported in a lecture[1] that he and his colleagues of the Imperial Cancer Research Fund had succeeded in transmitting mouse sarcomata by means of tissues which had been frozen and dried. The importance of such a finding could not be doubted. Until then there had been an apparently complete contrast between the bulk of mammalian tumours having no obvious continuing cause and a few growths, particularly fowl sarcomata, in which was *evident the activity of a virus as a continuing cause of* the malignancy. Professor Gye's report gave reason to believe that now, in mammalian growths also, was to be found a virus-like neoplastic agent. He made quite clear his belief that in the dried and even in the frozen tissues no surviving intact cell could be held responsible for the malignant activity.

This report caused much comment, discussion, and criticism. Scientists are perforce a race of sceptics, and a discovery as important as this was not likely to be accepted generally until it had been confirmed by others and until the interpretation was beyond doubt. Many have therefore awaited with eagerness the full technical details which will permit others to confirm—or refute—the claims made. The foundation of all the work consists of Dr. James Craigie's improved devices, especially those for finely mincing and for drying tumours; a description of these is still in the press. Meanwhile, we publish to-day three very important papers by Miss Ida Mann; these make it clear that the new techniques will give results not only with mouse sarcomata but with adenocarcinomata also. They go far to answer the questions we raised in discussing this matter in March.[2]

It is now plain that it is not just a few mouse tumours which can be transmitted by means of frozen or dried tissue, and that a principle is concerned applying equally to epithelial and to connective-tissue growths. Miss Mann's results also shed light on what is potentially the most controversial question of all: is it certain that these violently treated tumours do not still contain some living cells? Until this point is proved all is in doubt. Some pathologists will find it impossible to believe that a complicated mammalian cell can survive thorough drying; and the histological evidence supports their doubts. Others will wonder if such survival may not after all be possible, particularly as the alternative is the abandonment of all orthodox views on the causation of cancer. Discussion could go on indefinitely in the realms of metaphysics and histology. Fortunately there seem to be ways of by-passing this obstacle.

A tumour virus causing sarcomata would be expected to infect wherever in the body it was introduced; it would find susceptible connective-tissue cells everywhere. But one causing carcinomata would be epitheliotropic and could hardly do so unless placed in juxtaposition to the right kind of epithelial cell. One can expect therefore to be able with epithelial growths to distinguish clearly between the results of transplanting an odd surviving cell and infecting cells anew with an active agent. A graft might grow anywhere; new infection could occur only where suitable epithelial cells were present. Where we are concerned with an agent believed to cause mammary tumours in mice we are, however, up against a difficulty, for mammary tissue exists almost everywhere in the mouse's subcutaneous tissue; there are rudiments even in male mice. So it is not surprising that frozen or dried mammary tissue is effective wherever it is introduced subcutaneously in mice of either sex. Cell grafts of the adenocarcinomata, however, will grow in the peritoneal cavity, where there are no mammary cells. Miss Mann's results show that the frozen adenocarcinomata, which grow readily in the subcutaneous tissues, fail to grow on intraperitoneal injection, or do so rarely and in circumstances where the carrying in of a few mammary cells on the needle cannot be excluded. There is thus an apparent qualitative difference between the results of propagation with cell grafts and with frozen tumour. Proof derived from this type of experiment might easily be made more convincing. Quantitative tests with serial dilutions of live cell suspensions on the one hand, and of dried or frozen tumour on the other, introduced (*a*) subcutaneously and (*b*) intraperitoneally, might bring out the fundamental distinction in behaviour even more clearly. Better still, experiments with carcinomata other than mammary ones should yield decisive answers. If it is proved that the successful transmission with dried or frozen tumour tissue depends on something other than a surviving tumour cell it is a reasonable working hypothesis, on the analogy of the fowl tumours, that the active agent is a virus. The agent seems, however, to be a very labile one; so it may not be easy to apply the necessary tests to determine whether it can be justly placed in that category.

Some of Miss Mann's experiments were with spontaneous mouse cancers in which Bittner's milk factor—

[1] *British Medical Journal*, 1949, 1, 511.
[2] Ibid., 1949, 1, 531.

or virus—is concerned. Here is at first sight a discrepancy. If these growths are "caused by a virus," how comes it that the Bittner milk factor produces them only after months and only in the presence of suitable hormonal activity, while the frozen cancer tissue is effective within days or weeks and in mice of either sex? Why is the milk factor relatively stable and the activity of the frozen tumour highly labile? It is suggested—but the thesis is not elaborated at all—that the virus can exist in two forms, one latent and presumably stable and the other active but labile. It is further suggested that the effect of oestrogen in male mice carrying the Bittner virus is to precipitate a change from the latent to the active form. These are interesting speculations, but the workers in the Imperial Cancer Research Fund will be wise not to try to move too fast. They have made an important advance, but the ground gained will need consolidating. Most pathologists have for years turned either a blind eye on the virus theory of cancer or at best a suspicious and wary one. Every item in the "newer knowledge" will have to be proved to the hilt, every step will have to be repeatable in other laboratories, every deduction shown to be inevitable. There is every hope that in the end the results will constitute one of the brightest chapters in cancer research.

BACTERIAL FOOD-POISONING

During the last ten years there has been a great increase in the number of recognized outbreaks of bacterial food-poisoning in this country. Improved diagnosis no doubt partly accounts for this, but much of the increase is real, and during the war years was associated with the introduction of communal feeding, often supervised by workers with little knowledge of food hygiene. It is important to distinguish the "infection" and the "toxin" types of food-poisoning. In the infection type the patient has ingested living organisms, usually of the salmonella but sometimes of the dysentery group. After an incubation period of 6 to 40 hours the illness begins suddenly with severe headache, vomiting, diarrhoea, and abdominal pain. There is commonly some rise of temperature. Patients usually feel ill for about a week; in debilitated subjects the infection may prove fatal. In the toxin type, which is most often due to *Staph pyogenes*, enterotoxin has been preformed in the food and consequently takes rapid effect—the incubation period being half to four hours. The illness is more severe but of shorter duration than the infection type, so that the symptoms are over within 24 hours. Food-poisoning caused by enterotoxin rarely proves fatal. Other organisms, such as *Proteus*, *Bact. coli*, and streptococci of *viridans* type, have with less certainty been suspected to cause food-poisoning.

The salmonellae most frequently responsible for food-poisoning are *Salm. typhi-murium* and *Salm. enteritidis*, formerly known as the aertrycke and Gaertner bacilli. They are both natural pathogens of rats and mice, whose excreta may thus contaminate food, and they are not uncommon in duck eggs. *Salm. enteritidis* is also a constituent of certain "rat viruses" used for the destruction of rodents. A report by Dr. M. J. Pleydell in this issue of the *Journal* shows how the contamination of food in a restaurant by infected rodents can cause an outbreak of food-poisoning. Other hosts of these organisms, of which there is a large number of named species, are pigs and cattle. Pork and beef may thus come under suspicion, and milk may sometimes contain *Salm. dublin*, which is the cause of a disease of cows. During the war food-poisoning was often traced to imported dried eggs, in which many new salmonella species were introduced into this country. In a recent issue of the *Journal* (July 16, p. 186) an outbreak of food-poisoning at a London hospital was described. *Salm. typhi-murium* was isolated from a number of those attacked, and there was little doubt that the vehicle of infection was a pudding made with duck eggs. Chronic human carriers are rare, but infection can arise from a temporary excreter who may have few or no symptoms. In another recently reported outbreak of food-poisoning among schoolchildren in Yorkshire (July 23, p. 239) milk supplied to the schools concerned was found to contain *Salm. typhi-murium*. A cowman at a farm supplying milk to the schools had been ill with diarrhoea and vomiting just before the outbreak, but had carried on with his work. In the infection type of food-poisoning the laboratory may help by identifying the organism in the faeces or vomit of the victim and in the suspected food, and by tracing the source and path of infection. The first duty of the investigator is therefore to secure any remains of the suspected meal before they can be discarded.

Food may be contaminated with staphylococci transferred by the fingers from the nose of food-handlers or from infected cuts or septic lesions. There is a high nasal carrier rate of coagulase-positive staphylococci in the general population. Not all of these organisms can produce enterotoxin, for the presence of which there is no good laboratory test other than those requiring a human volunteer, but the bacteriologist can help by finding whether the food contains large or small numbers of staphylococci and by identifying their serological and bacteriophage type with that of the organisms found in the food-handlers and possibly in the victims. There is a significant association of one particular type, 6/47 IIIc, with food-poisoning outbreaks. It must be

remembered that the enterotoxin is heat-resistant and that bacteriological examination of the offending food and of specimens from the patients may therefore give negative results.

The foods commonly associated with food-poisoning are those which are handled during preparation and in which bacterial multiplication can take place. They include brawn, meat pastes, pressed beef, gravies and sauces, cream and custard fillings, and ice-cream. The taste and appearance of the food may be unaltered. A factor in most outbreaks is the keeping of food at some stage in a place which is insufficiently cool. In this way, for example, organisms in reconstituted dried egg readily multiplied to a dangerous concentration overnight at warm-room temperature. The general measures for prevention of these outbreaks are clear. Some of them, such as rodent control, the hygiene of slaughter-houses, and the adequate cooking of such foods as duck eggs, have already been indicated. Food should be prepared and served by clean workers, cleanly clad. They should be trained to report even trivial diarrhoea, cuts, and septic lesions, and they should have satisfactory hand-washing facilities. Manual handling of food should be reduced to a minimum; food wrappings and covers used where possible, and foods kept cool between the stages of preparation and during storage. Not least important is the hygiene of the kitchen: apart from its construction, the lighting, ventilation, proofing against flies and vermin, and facilities for the cleansing of utensils should all be of a high standard. By the intelligent application of common-sense principles it should be possible to minimize at least one menace of the warmer weather.

P.R.C.S. AND P.R.C.O.G.

Lord Webb-Johnson, as we announced in last week's *Journal*, has been succeeded as President of the Royal College of Surgeons by Sir Cecil P. G. Wakeley, and thus brings to an end a memorable period of office. As Sir Alfred Webb-Johnson he was elected P.R.C.S. in 1941, a year before the publication of the Beveridge Report, which, among other things, led up to the introduction of the National Health Service last year. Lord Webb-Johnson guided the affairs of the College of Surgeons during the greater part of the war, but, in spite of the difficulties inseparable from the time, he planned wisely and well, building up the College to a height of efficiency and enterprise not witnessed before. Departments were established and professorships endowed for anatomy and pathology; in the College laboratories practical teaching was made available for postgraduate students seeking higher qualifications; a research chair in ophthalmology was instituted; and under the new charter faculties in dental surgery and in anaesthetics have been established in the College. Under Lord Webb-Johnson the Royal College of Surgeons has become not only an international centre for teaching and research but also a social centre where Fellows and Members may meet each other at lunch and dinner. In a time of stress and controversy he held firm, in the face of much opposition, to what he believed to be for the good of his College and of the medical profession. His successor, Sir Cecil Wakeley, has a hard task to follow in office a man who has achieved so much. Those who know Sir Cecil Wakeley in his combined capacity as surgeon and editor will wish him success in the distinguished position he now holds.

Professor Hilda Lloyd has been elected President of the Royal College of Obstetricians and Gynaecologists in succession to Sir William Gilliatt. She is the seventh President of the Royal College, which was founded in September, 1929, as the British College of Obstetricians and Gynaecologists, and she is the first woman to hold that office. Mr. William Gilliatt (as he then was) took office in September, 1946. He was knighted in the Birthday Honours in 1948, and in November of that year attended Princess Elizabeth when her son was born. Professor Hilda Lloyd is professor of obstetrics and gynaecology in the University of Birmingham.

The burden of office in these days falls heavily upon the Presidents of the Royal Colleges; indeed, to be President is now almost a full-time occupation. Those who govern the destinies of the Colleges may well see fit to devolve more responsibility on to permanent officials, so that the President may have more opportunity to carry on his professional work.

THE AETIOLOGY OF CONGENITAL MALFORMATIONS

The statistical significance of foetal malformation as a frequent cause of stillbirths and neonatal deaths has been known for a long time and is easily demonstrated. Recently the possible causes of malformations have been studied with increasing intensity. The importance of the subject in preventive medicine can be judged from Malpas's[1] finding that either anencephaly, hydrocephaly, spina bifida, or mongolism was present in 1% of all infants born at the Liverpool Maternity Hospital. The influence of heredity in these conditions is very difficult to determine, though studies on familial cases have been made by Schade,[2] Penrose,[3] and Murphy.[4] Experimental and clinical evidence about the environmental factors which are associated with the development of malformations is, however, rapidly accumulating. Working in the field already investigated by Warkany, who induced malformations in the offspring by restricting the diets of the mothers, Gillman and his colleagues[5] have reported that malformed offspring are regularly produced if female rats are saturated with trypan blue injected before pregnancy begins and during its early stages. Injections were given at regular 14-day intervals, and it was found that when an injection fell on the eighth day of pregnancy or thereabouts more than half the offspring were

malformed. The commonest conditions were hydrocephaly and spina bifida.

These writers consider that, since the dye does not enter the foetus, the effect is analogous to that produced by virus infections (such as rubella) and is due to disordered maternal metabolism. This interpretation would seem to agree with the views expressed by Gruenwald,[6] who suggests that foetal changes may be secondary to the toxic effects of rubella in the mother. On the other hand, Hamburger and Habel[7] infected chick eggs with influenza virus and found that this impaired the growth of the embryos and caused microcephaly. Similar injection of mumps virus increased the liability of the chicks to develop malformations which otherwise occurred spontaneously in the stock animals. This work tends to support the views of Bardram and Broendstrup,[8] who examined eight children with eye disease (cataract or retinal degeneration) whose mothers had had rubella in the first two months of pregnancy. The pathology of virus infection in the developing embryo would scarcely be expected to follow the same pattern as infection in the adult.

A perplexing feature of all these investigations is the variety of malformations apparently due to the same cause as well as the variety of causes leading to similar end-results, though in the case of maternal rubella the picture is becoming clearer. Grouping together all kinds of foetal defects, Grönvall and Selander[9] found four or five cases of maternal rubella and five cases of maternal mumps among 354 mothers of malformed infants. They estimated that these numbers, though small, were far in excess of the expected numbers of maternal infections of this kind based on a large random series of births in Sweden. Retinal degeneration and deafness were found in the children of the mothers who had had rubella, and mongolism and defects of the nervous system in the children of the mothers who had had mumps. Landtman[10] compared the maternal histories of 73 malformed offspring with a control group. He found that acute infectious disease had occurred during the first three months of pregnancy in 12 (16%) of the mothers of the malformed children, but in only three (1.5%) of the mothers of 200 normal children in the control group. Influenza was the commonest infection, and the associated abnormalities ranged from spina bifida to congenital heart disease and naevus. The greater liability of older mothers to bear malformed children, many times previously observed, was confirmed. This is particularly noticeable for mongolism. Ingalls[11] has commented upon it and suggested that the causes of mongolism are multiple: he includes many pathological uterine conditions and intercurrent infections as aetiological factors.

It seems now to be accepted that maternal illness, especially when due to virus infection, occurring in the early months of pregnancy, may frequently be a contributory cause of foetal malformation and occasionally the whole cause. There are also genetical causes less easily controlled. The results of recent work on this subject, previously considered one of the most intractable problems in medicine, are encouraging. But the modes of action of abnormal genes and abnormal environments on the developing embryo are extremely obscure, and there is sometimes a tendency to lose sight of the ordinary scientific aim of finding specific causes for given effects.

PORTAL HYPERTENSION

Since surgeons have developed the technique of venous anastomosis the outlook for the sufferer from portal hypertension has improved. Without operation the patient with liver cirrhosis has only a 50% chance of surviving a year after the first haematemesis,[1] and for patients with Banti's syndrome the prospects are also gloomy. Until a few years ago surgery could do little for these patients, for Morison's operation of omentopexy did not increase the survival time.[2] Since 1945, however, through the development of the vitallium-tube technique of Blakemore and Lord and the improvements in suture anastomosis developed by Gross and Blalock, it has been possible to make a junction between the portal and systemic venous systems, with consequent relief of the portal hypertension.

Several series of cases are now available for analysis, the largest being that of Blakemore,[3] who has followed the progress of 58 patients for up to three and a half years after operation. The principal indication for a venous anastomosis is persistent and protracted haematemesis from oesophageal varices, which, according to Linton and his colleagues,[4] can and should be demonstrated by barium swallow in nearly all cases. These authors have found that the injection of sclerosing agents into the varices does not stop or prevent bleeding, one of their patients having been treated thus 15 times without benefit. Splenectomy, too, is not a reliable treatment in portal hypertension,[5] except in cases of thrombosis limited to the splenic vein, and a number of patients with Banti's syndrome have required subsequent venous anastomosis because of continued haematemesis. If the patient is unfit to withstand the bigger operation, ligation of the splenic artery, which is followed by atrophy of the spleen, is reported to have given good results.[6] Those with most experience[1 4] are agreed that splenectomy alone should not be done in cases of Banti's syndrome if there is evidence of portal hypertension, since the chances of successfully anastomosing the splenic and renal veins at a later date are thereby greatly reduced, and anastomoses using smaller veins, such as the inferior mesenteric, have given disappointing results.

Linton and his co-workers[4] state that any surgeon who performs splenectomy in Banti's syndrome should be prepared to make a spleno-renal vein shunt at the same time. This is the type of anastomosis now usually performed. It is preferred to the portacaval shunt because the latter is more difficult, and sometimes impossible, to perform, and it is more dangerous to important structures such as the hepatic artery and the common bile duct. Removal of the spleen is desirable, since this reduces the portal circulation by 30 to 40%. Furthermore, there is evidence from experimental work that complete diversion of the portal blood away from the liver leads to slight functional and structural derangements in that organ. Of the spleno-renal anastomoses, that now preferred is a sutured junction between the end of the splenic and the side of the left

renal vein. This has the merit of preserving the left kidney, and the anastomosis remains patent in experimental animals much more often than does end-to-end anastomosis by suture.[7] Vitallium-tube anastomoses are even more liable to become thrombosed and are no longer used in this operation by their originators.[1,8]

The choice of cases suitable for operation is important if the mortality rate is not to be excessive, and the degree of liver damage appears to be the principle criterion, apart from general considerations. In Linton's series the operative mortality was 71% in the cases with cirrhosis of the liver, but those without liver damage all survived. One point of practical importance is that the severely damaged liver does not appear to metabolize sodium citrate, and after a large transfusion of citrated blood the power of coagulation may be lost. One patient received no less than 48 pints (25 litres) of blood—mostly his own removed from the abdomen by suction—and did not survive. However, Blakemore had only three deaths in 39 cases with liver cirrhosis—all three had severely damaged livers—and it seems that the operation in patients with cirrhosis is not unduly hazardous, especially if cyclopropane is used as the anaesthetic, provided the serum albumin is not too low and the alkaline phosphatase not too high.

On completion of the anastomosis the portal pressure falls from up to 500 or more millimetres of saline to about 200 mm., and the subsequent progress of most of the patients has been very satisfactory, with a notable freedom from further haematemeses and a great improvement in the general health. There can be no doubt that the surgical relief of portal hypertension is an important development which has greatly improved the immediate outlook for sufferers from this disorder. Whether or not the anastomosis remains patent and the improvement is maintained indefinitely will be known as time passes, but certainly relief for up to four years is a great advance on previous treatments and holds out much hope of permanent benefit.

PERTUSSIS AND MENTAL DEFICIENCY

In the aetiology of mental deficiency heredity is not the only important factor. Injury or infection of the brain can produce irreversible damage, and many cases of mental defect are due to birth injuries, especially in premature babies. The possibility that the common infectious diseases of childhood may in some cases interfere with normal mental development has recently been considered, and Levy and Parry[1] have provided some evidence to support the hypothesis that an attack of whooping-cough may cause mental deterioration. They investigated a group of 1,000 children admitted to a special school for intellectually retarded children in Washington, with a view to determining whether an attack of whooping-cough at any age might have been the sole factor responsible for a child's backwardness. The records of these 1,000 children showed that 350 had a history of whooping-cough before admission. A questionary was sent to the parents or guardians, but replies were obtained only in 213 cases, and of these 85 had to be excluded because either the attack of pertussis was denied or insufficient information was given. After a careful study of all the relevant factors the authors concluded that in 20 (15.6%) of the 128 children there was a definite causal relationship between the attack of whooping-cough and the intellectual retardation that followed. The age of attack was important; the number of children whose mental retardation was attributed solely to whooping-cough was 14 (29.2%) of the 48 children who had the disease before they were 2 years old, 5 (14.3%) of the 35 children attacked between ages of 2 and 5, and only 1 (2.2%) of the 45 children attacked after 5 years of age. The conclusion that an attack of whooping-cough can lead to serious mental deterioration seems to be justified. The children studied had intelligence quotients of 70 or less, and border-line cases were not included. It is therefore possible that whooping-cough may be a cause of dullness among the general population of children.

SWIMMING-POOLS AND RESPIRATORY DISEASE

Among the conditions said to be transmitted on occasions by swimming-bath water are sinus and respiratory infections, enteric fever, skin diseases, Weil's disease, and some of the virus infections of childhood. As Suckling[1] has pointed out, the danger has probably been exaggerated, and it is likely that in many cases, especially in bathers whose vitality has perhaps been lowered by prolonged immersion, the disease is transmitted by more direct forms of contact. It is generally agreed that the risk is greater in the case of sinus, eye, and ear infections, and with respiratory diseases, than with intestinal infections. In this connexion a recent report by Gallagher[2] is of interest. The author, who is physician to a boys' boarding school in Massachusetts, noted the incidence of respiratory disease in the boys during the first eight weeks of seven successive years—this being the season when such disease was most prevalent. The school had an indoor chlorinated swimming-pool, and the boys were grouped as regular swimmers, occasional swimmers, and non-swimmers; the observations refer mainly to the first and last groups. The non-swimmers were not necessarily unable to swim, but were boys who chose to go in for some other form of sport. Variable factors in the two groups made assessment of the findings difficult, and figures from any one year might clearly have been misleading, but certain observations taken from the series as a whole are perhaps significant. The average number of admissions to the school hospital on account of respiratory illness was about 14% greater for the regular swimmers than for the other groups. Acute sinusitis was twice as common, and colds and acute pharyngitis slightly more common, in the regular swimmers than in the non-swimmers, but there was no constant difference in the incidence of influenza, streptococcal throat infections, or otitis media. In one year in which the numbers of cases were sufficient to make comparison worth while the number of cases of measles was 33% greater, in proportion to the size of the group, among the regular swimmers than among the non-swimmers. Similarly in another year there were six times as many cases of mumps among the swimmers as among the non-swimmers. The

New Engl. J. Med., 1948, **238**, 899.

inference is that after the occurrence of the first case of measles or mumps in the swimming group the risk of spread is greater than among the non-swimmers. A further observation was that over the whole period the non-swimmers had on the average 14% fewer days in hospital because of respiratory illness. Gallagher's conclusion is that with careful control and reasonable precautions the benefits of a swimming-pool outweigh any possible risk of spreading infection.

MEPACRINE DERMATITIS

In 1943 Peterkin and Hair[1] observed an eruption of the skin in soldiers serving in North Africa, and they saw a similar condition later in Italy; they believed this to be caused by mepacrine, and American dermatologists were of the same opinion. At about the same time a similar dermatosis was observed among soldiers taking mepacrine in the New Guinea–North Solomons area, and later in the Philippines, Australia, and India.[2-8] Pruritus was severe in most patients, but constitutional symptoms were usually absent. An acute onset, with generalized erythema, was followed by the development of chronic lesions. Nisbet[9] found a chronic symmetrical eczematoid eruption in 80% of the cases he saw, the commonest sites being the ears, eyelids, periorbital region, the backs of the hands and feet, and those areas most often affected in seborrhoeic dermatitis. In 12% of the cases pigmented flat or hypertrophic lichenoid lesions developed, with patchy alopecia. This type of eruption was more widespread than that of ordinary lichen planus. Lesions resembling lichen planus, leucoplakia, or syphilitic mucous patches appeared on the tongue and mucous membranes of the mouth. Dystrophy of the nails resembled psoriasis or fungous infection: a case in which this sign was prominent was reported recently in this *Journal* by Dr. G. H. V. Clarke (July 9, p. 58). Exfoliative dermatitis was sometimes a primary reaction, or it might follow the eczematoid or lichenoid eruptions; it was similar to that caused by the organic arsenicals and was occasionally fatal. A resemblance to Riehl's melanosis was noted by Sulzberger[10]—lichenoid, pigmentary, atrophic, telangiectatic, and poikiloderma-like changes being present in both. This observation is of interest, because Riehl's melanosis appeared in Vienna after the 1914–18 war[11] and acridine derivatives were among the suspected causes.[12] Other diseases which may resemble mepacrine dermatitis are lupus erythematosus, psoriasis, pityriasis rosea, and seborrhoeic eczema.

The incidence of mepacrine dermatitis among troops was difficult to assess. In the Pacific zone Williams[7] found 0.5 cases per 1,000 in a New Zealand division and Alden and Frank[8] 0.6 per 1,000 in American troops. Pillsbury and Livingood,[13] however, thought it probable that "at least 1% of all persons in hot, humid, tropical overseas areas who took quinacrine hydrochloride in suppressive dosage over a period of at least six months acquired some type of cutaneous reaction."

It is now agreed that the ingestion of 0.1 g. or more daily of mepacrine for several months was the cause of this condition. Inder Singh,[14] who has recently described the occurrence of mepacrine dermatitis in labourers in India, considers, like Nisbet, that the accumulation of mepacrine in the skin depends on the dose and the rates of absorption and of excretion. Thus lesions recur after a latent period of one or more weeks when mepacrine is again given to patients who have recovered. Similarly, larger doses of mepacrine may produce lesions in patients previously unaffected. Several authors have noted a seasonal incidence, and Singh agrees that mepacrine dermatitis is more common during the hotter and more humid months. This may be due to diminished urinary output of mepacrine and perhaps to a combination of profuse sweating and the deposition in the skin of an insoluble form of mepacrine. The treatment of the condition is to hasten elimination of the drug by a large fluid intake and the administration of acid salts.

COARCTATION OF THE AORTA

An unusual study of coarctation of the aorta has been made by Newman,[1] who has examined the histories of 20 patients who served in the recent war and three in the 1914–18 war. These patients, all men, were examined on enlistment, but coarctation was not diagnosed until later, generally after years of very strenuous activity. Most of them were of good or even powerful physique. It would be interesting to know how many men were rejected by medical boards for coarctation, since 20 cases among the huge population which the armed Services represented would make coarctation a much rarer defect than it is believed to be. How the correct diagnosis eventually came to be made, whether from symptoms or from signs found on routine examination, is not entirely clear, but it would appear that in a number of the men the discovery was made from the appearance of rib notching in a radiograph of the chest. This was present in 16 or 17 of the 23 cases. In one in which there was no notching the aortic knob was prominent and high—a finding which shows that the characteristic radiographic signs in the chest cannot be relied upon. Hypertension in the arms (usually greater in the right arm) was an almost constant sign, though in one subject the reading was only 144/90. An important observation was that cardiac enlargement, which was usual, bore no relation to the height of the blood pressure. When recorded, the arterial pressure was always less in the leg than in the arm, and in many of the cases the femoral pulse was absent. The other most frequent signs were a systolic murmur over the praecordium (sometimes also heard over the back) and a collateral circulation over the chest. Of the 20 men who served in the last war, three have died—one from rupture of the aorta, one while being operated upon for the coarctation, and one from subacute bacterial endocarditis. The three cases of the 1914–18 war were known to have survived an average of 24 years before death or the onset of very severe symptoms.

INTERNATIONAL CONGRESS OF OTOLARYNGOLOGY

LONDON MEETING

The fourth International Congress of Otolaryngology was held at King's College, London, last week. The assembly was attended by 725 members and 72 scientific associates, all medical men practising the specialty, and some forty countries were represented. The Congress was opened on July 18 by H.R.H. THE DUCHESS OF KENT, who said that so large a gathering, representative of so many nations, was evidence of advancing knowledge and of the increasing importance attached by physicians and research workers to a subject which bore directly on the lives of all. Her Royal Highness was welcomed by Mr. V. E. NEGUS, the president of the Congress, and thanks were expressed to her by Mr. F. C. W. CAPPS, the general secretary.

In 1928 the first International Congress was held at Copenhagen, under the presidency of Professor Schmiegelow, who died during the past year. The second was held at Madrid in 1932 and the third in Berlin in 1936, under the presidencies of Professors Tapia and von Eicken respectively. The fourth would have been held in Amsterdam in 1940 had the war not intervened.

A full programme was arranged for the London Congress. About 150 papers were presented, most of which were discussed in four sessions sitting simultaneously. There were three general discussions, the first on antibiotics and chemotherapy in the treatment of nasal sinusitis and its complications, which was opened by Sir Alexander Fleming and Sir Lionel Whitby. The second was on the treatment of aural vertigo, and the third was concerned with non-malignant strictures of the thoracic oesophagus and their treatment. In addition there was an almost continuous programme of films, by which many of the American and Continental visitors demonstrated their operative techniques. Visits to hospitals and clinics were arranged, and receptions were given by H.M. Government, the London County Council, the Royal College of Surgeons, the Royal Society of Medicine, and the British Medical Association. After their strenuous week in London the visitors separated for meetings in Oxford, Cambridge, and Edinburgh.

Treatment of Aural Vertigo

About twenty speakers took part in a discussion on aural vertigo, which was opened by Professor F. R. NAGER (Zurich). He said that the pathogenesis of the condition was still largely unknown, and several diseases probably contributed to it. The theory of allergy had been rejected in many quarters. Professor C. NYLEN (Uppsala) gave a survey of 180 cases seen between 1944 and 1948, the majority of which were treated conservatively during the critical period by confinement to bed, a special diet (which included extra vitamins), and restriction of fluids. About 70% of the cases treated in this way recovered or improved considerably. Operative treatment had been undertaken in only a few cases; in five the vestibular nerve had been cut.

Dr. W. J. MCNALLY (Montreal) reviewed a series of 200 cases seen over ten years. It was not easy, he said, to make a diagnosis of aural vertigo, and the triad of dizziness, deafness, and tinnitus was present in only about half the cases. It was significant that in about 50 of these patients there was definite evidence of advanced cardiovascular disease. He felt that cardiovascular disease and disease of the central nervous system might play an important part in the aetiology of this condition. A history of allergy was given in about 50 of the cases. In aural vertigo there were long remissions, and in this series the longest, up to four years, had been found in patients who had received no treatment at all. Treatment had been confined to sedation in some cases, but at best this produced only a temporary result. About half the patients were placed on a modified salt-free diet and given potassium chloride. About 30 had histamine, in most cases administered subcutaneously, and in about half of these relief from dizziness was obtained. Histamine brought about an improvement in hearing also. Nicotinic acid had proved useful, and about three-quarters of the patients so treated showed signs of improvement. Nine cases were treated surgically (by eighth nerve section), of which five were cured. He felt that surgery should be rigidly restricted to carefully selected cases.

Dr. J. A. SULLIVAN (Toronto) also urged severe restriction of surgical intervention. The fenestration operation had in his experience made the condition worse, and he had been obliged to subject the patient to further intervention later. Dr. E. P. FOWLER (New York), who suggested that the term "otic vertigo" was more appropriate and less confusing than "aural vertigo," gave an account of eight patients with either bilateral or very severe symptoms who had refused operation and were treated with streptomycin. One of the cases had a further severe attack one year after treatment, but the others had so far done well. The effect of small doses of streptomycin on the vestibular cells was good and free from deleterious effects. Dr. C. A. HAMBERGER (Stockholm) gave an account of the chemical changes in the vestibular ganglion in guinea-pigs after administration of streptomycin. The effect of the streptomycin appeared to be selectively linked to the eighth nerve.

Other speakers in this discussion were Professor Y. MEURMAN (Helsinki), Professor G. PORTMANN (Bordeaux), Mr. T. E. CAWTHORNE (London), Dr. C. A. AMESUR (Bombay), Mr. GARNETT PASSE (London), Dr. J. M. TATO (Buenos Aires), Dr. H. M. GOODYEAR (Cincinnati), and Dr. D. E. WODEK (Tel Aviv). Dr. Wodek described the treatment of aural vertigo by a new drug called scopanin, which was manufactured from the root of the mandragora. He said that it had proved useful and without side-effects, and was effective also in air- and sea-sickness.

Changes in Aural Surgery

The fenestration operation was the sole topic of discussion at one session, at which Dr. J. A. SULLIVAN (Toronto) gave the results of ten years' experience, and Professor M. SOURDILLE (Strasbourg) demonstrated his surgical technique.

Mr. T. E. CAWTHORNE (London) said that the last few years had witnessed a great change in the type of surgery performed by otologists. The surgery of suppuration was diminishing rapidly, while non-suppurative surgery was expanding at an almost equally rapid rate. It was therefore important to consider the new techniques that non-suppurative surgery demanded. Changes in aural surgery had been accompanied by extensive alterations in technique and management. Until the present century it was considered that any approach to the bony boundaries of the labyrinth rendered it extremely vulnerable to infection, and as a result operations were generally, and not without justification, viewed with disfavour. The greatest advance in aural surgery had been the demonstration that non-suppurative conditions of the temporal bone could be operated on without subsequent infection, provided the general rules of aseptic surgery were observed.

Non-suppurative surgery of the temporal bone demanded for its proper performance a brilliantly lighted field, for the parts to be operated on were small and delicate. In the past many surgeons had been handicapped by inadequate illumination for their task. Another important development was magnification, some degree of which was necessary in such surgery. With a bright beam of light reflected by a mirror, and the use of a microscope, many things were shown which might otherwise escape detection. But the full benefits of illumination and magnification could not be obtained if the field was obscured by blood. Any anaesthetic which caused congestion was to be avoided. Local bleeding must be controlled by diathermy. For many of his finer instruments the otologist was indebted to his ophthalmic and dental colleagues. In the fenestration operation, for instance, fine dental instruments were needed to clean the edge of the fenestra. The margin of error in many of these operations was small, and no one should undertake them without adequate training on the cadaver. The sphere of the otologist had been enlarged. He was now able to restore equilibrium to the unbalanced and even give hearing to the deaf.

Antibiotics in Nasal Sinusitis

A discussion on antibiotics and chemotherapy in the treatment of nasal sinusitis and its complications was introduced by Sir ALEXANDER FLEMING, who referred to the role of penicillin and other antibiotics in this connexion. Twenty speakers from more than a dozen countries participated in the discussion. Sir LIONEL WHITBY said it might be asked whether the sulphonamides had any place in the treatment of nasal sinusitis now that antibiotics had come into use. He would answer yes for two reasons: one, the availability of these products, and the other, the fact that the sulphonamides had a significant action on Gram-negative bacteria. But if sulphonamides were to be used in nasal sinusitis it was important to bear certain principles in mind, because the use of these drugs was not without risk, whereas with penicillin there was no risk at all. The most useful action of the sulphonamides was probably prophylactic; this was particularly true in tonsillar and nasal infections. They had a useful place in the early stages of acute infections, but in chronic infections they were disappointing unless free drainage was established. On occasion they might be successful where penicillin failed.

Sir ALEXANDER FLEMING said that he was told by his ear, nose, and throat colleagues that penicillin had made a considerable difference in the treatment of nasal sinusitis and its complications. This was only to be expected from the fact that nearly all infections of this class were due to organisms which were sensitive to penicillin. In such cases the treatment resolved itself into the introduction of penicillin so as to ensure that it reached the infecting organisms and remained in contact for a sufficient time to destroy them. Perhaps the most important advances in penicillin therapy had been those designed to prolong the action of penicillin injections, especially by delaying excretion. Systemic administration of penicillin was easy; it was very different with local administration. Here the surgeon had to bring the drug into contact with all the infecting organisms, and this might be difficult or impossible. Sir Alexander concluded by remarking that under present circumstances patients would often be treated with these selective drugs without bacteriological control. When the surgeon was treating sinusitis he was not merely combating a word ending in "-itis": he was in conflict with a definite infection, and he was at a serious disadvantage if he knew nothing of the organism involved.

Dr. H. P. SCHENCK (Philadelphia) said that the value of the antibiotics and sulphonamides had inevitably been depreciated by errors in the hands of the inexperienced. Although the mistakes of insufficient dosage, administration at an improper rate and for an inadequate interval, or use against non-susceptible organisms had come to be generally recognized, other pitfalls remained. He condemned in particular the use of aerosols in the treatment of most forms of sinusitis. It was inconceivable that such mists could penetrate diseased sinuses which were closed by an oedematous mucosa or by tenacious secretions. Such aerosols undoubtedly had value in the nasal passages themselves, but they were unable to enter the sinus cavities in sufficient concentrations to be therapeutically effective. The fallacy of attempting to influence the fluid level in the maxillary sinus by the use of antibiotic aerosols alone was obvious. Removal of obstructions to drainage and ventilation, shrinkage of turbinal tissue, and sometimes displacement irrigation continued to be necessary in addition to chemotherapy if a successful result was to be achieved.

Non-malignant Strictures of Oesophagus

Another general discussion was on non-malignant strictures of the thoracic oesophagus and their treatment. Before calling upon Dr. Gabriel Tucker, of Philadelphia, to open the discussion, Mr. V. E. NEGUS, president of the Congress, said that in the treatment of some of these oesophageal conditions in this country great benefit had been obtained from Dr. Tucker's dilating bag—a bag with three layers which collapsed to a small size and could be used with the oesophagoscope. He had found it extremely useful. For its introduction, in certain cases, it was an advantage if the centre was perforated so that it could be introduced along a guide. It was sometimes wrongly described in this country as the Negus bag. He always took occasion to correct that description and to assign the credit where it belonged—to Dr. Tucker.

Dr. GABRIEL TUCKER recounted his observations on a series of cases, seen in a period of 25 years, with special reference to diagnosis and treatment. These included 36 cases of short oesophagus, 63 of stricture caused by caustic burns—alkalis, acids, and other corrosives—and a smaller number due to other trauma or of congenital origin. He showed a film to illustrate his procedure of continuous string retrograde dilatation in the patient with a gastrostomy.

Dr. CHEVALIER L. JACKSON (Philadelphia) said that the prevention of caustic burns of the oesophagus had been the subject of campaigns in the United States. Many years ago Chevalier Jackson, senior, had been active in promoting committees which caused various States to introduce legislation on the labelling and sale of substances which produced such burns. Now a Federal Act had been passed to the same effect, and the incidence of these accidents had been greatly reduced. In simple stenosis due to burns, dilatation with oesophageal bougies was generally sufficient. In multiple strictures, however, and even in single strictures in children the retrograde dilatation method of Tucker was considered to be safer and more efficient. If the stricture was of longer than a year's duration it might not be possible to re-establish the passage by endoscopic methods, but he believed that in cases with less than a year's history the passage could be re-established under fluoroscope guidance, even though the patient was not able to swallow well.

Dr. P. H. HOLINGER (Chicago) said that in the dilatation treatment of stricture caused by caustics his practice was to use mercury-filled bougies. Indwelling tubes had been abandoned because of the tendency to post-cricoid ulceration. A new problem was presented by post-surgical stricture following section of the oesophagus for carcinoma or for benign lesions, which sometimes substituted a benign nodular type of stenosis for a smooth cicatricial type. Another group comprised children with tracheal stricture associated with atresia or stenosis of the oesophagus. Professor ODD OPHEIM gave an analysis of the treatment of burns of the oesophagus in two hospitals in Oslo during a five-year period. In all, 132 patients had been observed, of whom 81 were children under 3. Four patients presented negligible corrosive marks in the oesophagus, or none at all, and these received no treatment. The other cases were fairly equally divided between those showing distinct but not deep-seated corrosion and those with major corrosive injuries. In these latter cases an indwelling tube was introduced and left in for at least eight weeks It was removed only for the necessary changes. Of 39 patients followed up in the first of these groups, 31 were found to be symptom-free, seven had marked, though not severe, swallowing difficulties, and one had died. In the group of major corrosive injuries, 28 out of the 39 whom it was possible to follow up were symptom-free, seven had swallowing difficulties, and three had died. Treatment had been singularly free from complications.

Dr. L. H. CLERF (Philadelphia) said that in most of his cases retrograde bouginage had been carried out. In cases in which gastrostomy had been done he had used the indwelling tube, placing it in position under fluoroscopic guidance and securing it with a thread above and a thread through the gastrostomy opening. Care must be taken that the thread was not behind the cricoid. Dr. F. T. LAND showed a series of cases from the Western Infirmary, Glasgow, of lesions of the lower third of the oesophagus. The presenting symptom was pain in three cases, dysphagia in ten, and pain and dysphagia together in 16. The lesions were twice as common in females as in males, and five of the cases of dysphagia occurred in pregnancy, all among older women (aged 36 to 42).

Other speakers from France, Finland, Austria, Holland, and Italy took part in this discussion.

Differential Diagnosis of Aural Vertigo

Mr. C. S. HALLPIKE (London) gave a paper on the pathology of aural vertigo. He mentioned three varieties of aural vertigo: (1) Ménière's disease, or idiopathic endolymphatic hydrops; (2) vestibular neuromatosis; and (3) positional vertigo. Ménière's disease affected chiefly patients aged 40–60. The

first attack of vertigo was unaccompanied by any history of head injury. Distortion of hearing was a common complaint, and tests of cochlear function showed considerable deafness. In the active phases of the disease loss of intelligibility in hearing was out of all proportion to pure tone audiometric loss. He emphasized the importance of changes in Corti's organ. Vestibular neuromatosis affected younger patients than did Ménière's disease, and was not uncommon between the ages of 20 and 30. The onset of symptoms was frequently connected with some infective illness. Unlike Ménière's disease, the symptoms might include transient "black-outs," and the condition persisted between the attacks as a feeling of lack of balance. A fair proportion of these patients were found to have oro-nasal infection. In positional vertigo the onset of symptoms might again date from an infective illness or head injury. Many cases showed evidence of focal infection in the territory of the ear, nose, and throat. Localized tenderness in the occipital region was noticed.

Dr. MILES ANDERSON (New York) discussed the evidence for vitamin deficiency as the basic disturbance in Ménière's syndrome. He had found that patients with this syndrome who were histamine-negative had severe deficiencies in nicotinic acid, while in the histamine-positive group the majority were severely deficient in riboflavin. Patients responded to treatment by means of vitamins, first with the fraction that was deficient and afterwards with the other fractions. The vaso-constrictor group responded to nicotinic acid and the vaso-dilator group to riboflavin.

Colds and Catarrh

Neurogenic factors in the common cold was the subject of a paper by Dr. E. P. FOWLER (New York). In the common cold of all types an emotional factor was very likely to be the precipitating one. It arose from a state of imbalance. He mentioned the well-known "courtship cold," the "honeymoon cold," and the catarrh of pregnancy. It was very common for a cold to develop on examination day or on a day of domestic upheaval, evidently due to changes in the nasal mucosa arising from an emotional cause. It was generally accepted that the common cold was due primarily to a virus infection, but the preparation of the "soil" must not be overlooked. If workers in certain dusty occupations and those in contact with infections were excluded, he believed that a large number of colds were of a neurogenic type, due to overaction of the sympathetic. Physostigmine or a similar drug was indicated instead of the usual sulphadiazine or penicillin. The outstanding prophylactic was emotional equilibrium.

Adenoids in the adult as the cause of chronic nasopharyngeal infection were mentioned by Dr. B. M. KULLY (Los Angeles). He considered that hypertrophy of the adenoids commonly persisted into adult life and was responsible for many catarrhs, low-grade fevers, and unexplained headaches. In 140 necropsies eight specimens were found of hyperplastic adenoids of infantile type in persons over 70 years of age. He was left with a feeling that adenoids were a primary factor in the causation of the common cold, and that the removal of adenoid tissue in the adult was one of the best means of diminishing the incidence of colds and their complications. He mentioned a number of persons whose hearing had greatly improved after the naso-pharynx was cleared by fulguration with high frequency, followed by irradiation.

Mr. O. POPPER (Johannesburg) brought forward the subject of the restoration of hearing in the "chronic ear." He said that there had been a spate of literature on this subject. If the character of infective deafness were analysed the elements which made up the pattern of the "chronic ear" would be found to include the obliteration of the round window by granulations or other proliferations, and the removal of the stapes from the oval window, causing disequilibrium. The first objective must be an unrestricted sound path. The "chronic ear" person, who did not even remember when he heard last, was sometimes inclined to write off his hearing. That the hearing could be restored by operative measures did not seem to have occurred to him or to his doctor, but the elimination of obstructive elements might restore it without any other operative procedure. Mr. Popper urged that the operation for the restoration of hearing was not an anatomical dissection and should not be too radical.

Dr. TAGE KJAER (Copenhagen) discussed bronchostenosis of inflammatory origin. He said that this was no uncommon condition. It could be divided into (1) acute and subacute catarrh with submucous swelling, and (2) a stenosis in which changes extended through the whole bronchial wall, with a tumour-like appearance in some cases. He analysed a series of 30 cases seen in Copenhagen, and gave particulars of their treatment.

Treatment of Acute Mastoiditis

Mr. J. I. MUNRO BLACK (Newcastle-upon-Tyne) gave an account of the treatment of acute mastoiditis in children by penicillin. Injections were continued until the swelling of the tympanic membrane had completely disappeared. The time necessary for this to take place was from four to fourteen days. In the majority of cases acute mastoiditis could be treated by penicillin injections alone, with perhaps incision of an abscess. Parents could be reassured that no immediate operation was required and that it was unlikely that surgery would be necessary at all. He thought that cases with otorrhoea did best with this form of treatment, and that this method should be brought to the knowledge of general practitioners. They should use penicillin early in the treatment of acute suppurative otitis media, with the object of preventing the formation of an abscess. This advice had been more welcome since procaine penicillin had become available, making possible one injection a day instead of four.

The operation of transmeatal attico-antrotomy was described by Mr. A. TUMARKIN (Liverpool). He said he had brought the operation to the attention of the Section of Otology of the Royal Society of Medicine two years ago. It had been criticized on the ground that it gave a restricted approach, but he found it had proved completely adequate in the majority of cases and he had never had to abandon an operation because the access was not sufficient. It was a logical procedure. It did not sacrifice the ossicular chain or disturb the normal tissues. The haemorrhage could be controlled. It was not an easy operation, but in hands possessed of reasonable skill it presented no special difficulty. He had now done 500 cases with no deaths and no major catastrophes. There were no instances of facial palsy. After-treatment must be carried out with care. He did not recommend the transmeatal approach in acute infections, nor when complications were present, but he had found it adequate for all "cold" surgery and he now used it for fenestration. The method permitted the surgeon to alter the operation in accordance with the pathological conditions he encountered. In days gone by operations were done to save life; to-day they should be done to save hearing also. Professor G. CORNELLI (Milan) read a paper on the transmeatal approach to the tympanic cavity.

Dr. A. J. CRACOVANER (New York) introduced the subject of bronchoscopy in the treatment of diseases of the lung. At one time this method was employed only for the removal of foreign bodies, but it was now used in many lung conditions. In lung abscess bronchoscopy should always be performed to determine the cause and exact location of the suppuration and to plan the necessary treatment. Bronchoscopic aspiration had been known to assist in the healing of an acute abscess. It was well to bronchoscope every case of bronchiectasis and every patient who had a thick exudate in the bronchus for any unreasonable time. In tuberculosis it was thought not so long ago that bronchoscopy was contraindicated, but this idea no longer held good. Certain definite indications called for bronchoscopy—for example, a patient with positive sputum but no other signs of tuberculosis. In cases of asthma which were not relieved by the accepted methods of treatment it should be borne in mind that the condition might be the result of bronchial obstruction. Dr. Cracovaner added that surgeons and anaesthetists were now using bronchoscopy, but it was only the specialist in this technique who could advance it and discover its possibilities.

Techniques of Examination

A demonstration of a simplified technique for direct laryngoscopy was given by Dr. SAM ROBERTS (Kansas City). He employed a special head block which ensured the head being

in the optimum position. The curve of the block held the head firmly and did away with the services of a trained assistant. Interest was also shown in a demonstration by Professor A. TRIMARCHI (Bergamo) of an apparatus which permitted the inspection of the larynx life-size or enlarged. Dr. P. H. HOLINGER (Chicago) showed his skill in endoscopic photography. His technique resulted in admirable pictures of the larynx and bronchus one-quarter of an inch (0.6 cm.) in diameter and capable of considerable enlargement.

A series of films by Dr. L. H. CLERF (Philadelphia), which included photographs of the normal larynx during respiration, phonation, and cough, attracted considerable attention. He also showed photographs illustrating unilateral and bilateral laryngeal paralysis following thyroidectomy, the technique of the modified King operation for mobilization and lateral fixation of the vocal cords, and the appearance of the larynx before and after operation. Another film, by the Edison Bell Telephone Company, showed the vocal cords in "slow motion," recorded on film at a speed of 4,000 frames per second. Perhaps the most remarkable of the films was by Dr. H. G. Kobrak (Chicago), who, by using optical magnification combined with stroboscopic illumination, had recorded the vibrations of the ear in response to sound stimulation. The film showed drum vibrations, movements of the ossicular chain, and vibrations of the round window membrane. The movements in disease were also shown, correlated with distorted acoustic signals recorded simultaneously on a sound track.

The presentation of 150 papers with only 15 minutes allowed for each gave a sense of haste to the proceedings, although discussion had generally to be entreated rather than curtailed in the intervals set aside for the purpose. Only a few of the speakers can be mentioned in a summarized account. Several papers on the surgical treatment of cancer of the larynx and the oesophagus were presented, also a number on the conservation of hearing and hearing-aids and on vocal cord paralysis.

Mention should be made of the exhibition illustrating the history of otolaryngology, which was arranged by Dr. Douglas Guthrie and Lieutenant-Colonel W. A. D. Drummond. It included a number of instruments designed by Morell Mackenzie, the manuscript of his work on malformations of the oesophagus, and his book *Frederick the Noble*, the story of the illness of the Emperor. The exhibits were from the collection of Dr. Irwin Moore and the Wellcome Historical Medical Museum. Other collections were of books, letters, and instruments associated with Sir StClair Thomson and with Lord Lister.

The delegates from overseas, who numbered some 450, expressed their appreciation of the arrangements for the Congress and of the kindness of their British hosts. During the course of the Congress the King, as Patron, sent a message expressing his good wishes for its success.

THE OFFICIAL BANQUET

The banquet in connexion with the Fourth International Congress of Otolaryngology was held at the Dorchester Hotel last week with the president, Mr. V. E. Negus, in the chair. There was a very large attendance of members of the Congress and their wives and guests. After the loyal toasts had been honoured, Sir Henry Dale, O.M., proposed the health of the Congress in a speech the keynote of which was international co-operation in medicine and science. There were, Sir Henry Dale said, forty different nationalities represented at the Congress. The King was the Patron of the Congress and the Duchess of Kent had opened it. "All London is eager to welcome you." Sir Henry pleaded that international science should be kept free from national prejudices. Science was one of man's intellectual activities which were universal. Sir Humphry Davy, he said, was during the Napoleonic wars received with courtesy by the Academy of Sciences in Paris, and it was in Paris in 1907 that Charles Richet made an impassioned appeal at the Congress of Physiology for abolishing barriers in the world of science. Sir Henry, recalling that Sir John Pringle had started the idea of the Red Cross, suggested that the symbol of the Red Cross should be kept flying over medical activities of all kinds.

In response Mr. Negus referred to the friendships which were established at congresses of this kind outside the halls in which scientific discussions were held. He paid tribute to Sir Henry Dale as one who personified the acme of science allied to medicine. Mr. Negus referred in particular to distinguished oto-rhino-laryngologists who had graced congresses in previous years—Professor Schmiegelow, of Copenhagen, Sir StClair Thomson, and Professor de Kleyn, of Amsterdam. Lord Webb-Johnson, to whom Sir Henry Dale had paid tribute for his work for the Royal College of Surgeons and in wider fields, proposed the toast "Oto-rhino-laryngology." He, too, referred to the need for international friendship and co-operation in science and medicine. The names of great surgeons had been associated with otology and of physicians with laryngology. He referred to the support given to the specialty by the Royal College of Surgeons. In response Dr. LeRoy A. Schall, of Boston, praised the action of the president of the Royal College of Surgeons in raising the prestige of the specialty of oto-rhino-laryngology. In proposing the health of the guests Mr. F. C. W. Capps, the general secretary of the Congress, said that between four hundred and five hundred members had come from overseas at great cost and trouble to themselves. This made the people in this country proud to hold the Congress in London. On behalf of the guests there were responses from Professor le Maitre, of France, and Dr. N. Rh. Blegvad, of Denmark, who entertained the diners by putting a viking's helmet on his head and a beard round his chin to illustrate what previous invaders of England had looked like.

UNICEF IN YUGOSLAVIA

The programme of work carried out in Yugoslavia by Unicef (United Nations International Children's Emergency Fund) was explained at a press conference at United Nations office in London. The cost of the programme so far has been ten million dollars, of which 60% has been spent on food. As many as 600,000 children, as well as expectant and nursing mothers, have been cared for. One of Unicef's principles has been to encourage communal meals at schools, partly because this is the most economical way of handling the food, and also because it is hoped that once a system of school feeding is established it will be made permanent. Unicef in Yugoslavia, as in other countries, is operating a programme of B.C.G. vaccination against tuberculosis. When this is completed it is thought that one and a half million children will have been vaccinated. An area of central Bosnia has suffered from an outbreak of syphilis not transmitted sexually. In some mountain villages the incidence among children was said by one American venereologist to be as high as 50%, and the children have passed the disease on to their parents. Procaine penicillin was being used in combating this outbreak.

D.D.T. was being used against malaria and fly-borne diseases. The previous work of Unrra in Yugoslavia and other countries had done a great deal to bring down the incidence of malaria, and it was said that for the first time since the second Punic war (218 B.C.) Italy had no deaths from this disease last year. This is attributed to D.D.T.

The organization also provided milk-processing machinery for the manufacture of powdered milk and for pasteurization. There was a shortage of milk, which was greatest in the mountains on the Dalmatian coast, but it was hoped to supply at least a minimum of clean, dried milk for use in every part of the country and at all times of the year.

Mr. Forrester, the agent of Unicef, who presided at the conference, said that in Europe four and a half million children were being given milk regularly every day by the organization. The continued need for the use of powdered milk since the end of the war had placed a strain on the manufacturing capacity. Opposition to communal feeding had been experienced from parents, who felt that what was provided in the home was good enough, but that opposition was breaking down. Another effect of Unicef work was upon labour productivity, for venereal

Ortho-Gynol Set

a Complete Convenient Contraceptive Unit

Ortho-Gynol vaginal jelly is now available with the new *Ortho-Vaginal Diaphragm* and *Diaphragm Introducer* complete in one prescription unit.

These handsomely packaged sets are also available as *Ortho-Creme Sets* (for those patients who prefer a cream to a jelly contraceptive).

In sizes from 55-95 mm for convenient prescription wherever in the opinion of the physician, the combination of a chemical contraceptive and a secondary occlusive device is indicated.

PRESSURE DRESSING FOR A SCALD

AUGUST 22nd, 1947. Scalded at work. Next day attended hospital with a large blister of inner aspect R. ankle (Fig. 1)

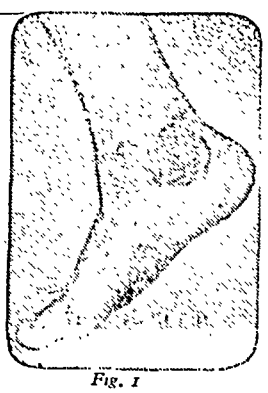

Fig. 1

Treatment. Scalded area dressed with Jelonet (tulle gras), Viscopaste bandage applied from toes to knee. Pressure pad of cotton-wool applied over scalded area. The whole leg firmly bandaged with Elastocrepe, with especially firm pressure over the scalded area. (Fig. 2).

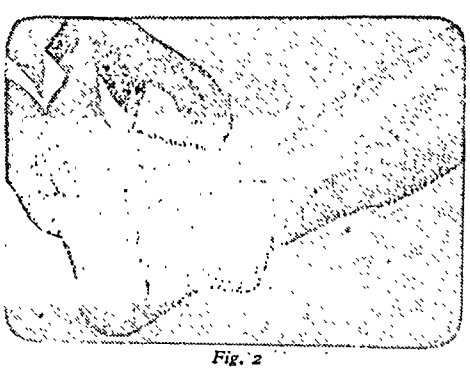

Fig. 2

7th October, 1947. When bandages were removed, wound soundly healed. (Fig. 3).

Comment. Firm pressure dressing afforded *immediate* comfort, permitting ambulatory treatment and continuation at work.

These details and illustrations are of an actual case. T. J. Smith & Nephew, Ltd., of Hull, manufacturers of Elastoplast, Elastocrepe, Jelonet and Viscopaste, publish this instance—typical of many—in which their products have been used with success.

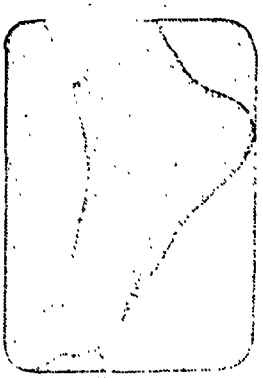

Fig. 3

carcinoma of the uterine cervix, the five-year survival figures (25% of all cases treated) are the same for patients who had serial biopsies as for those who did not. From St. Mark's Hospital it is reported that biopsy has proved a reliable aid to diagnosis in rectal cancer. The procedure should be more generally employed, especially in cases where the clinical diagnosis is uncertain.

This document, although it is a collection of reports which often overlap, contains many interesting facts and figures. For example, there is the observation from St. Bartholomew's Hospital that the incidence of uterine cancer among Jewish women is lower than among non-Jewish. This is more remarkable because Jewish women seem to be particularly subject to conditions (early marriage and child-bearing and, in some communities, low economic status) which in other people appear to increase the liability to this form of cancer. The report not only records work which has been done but poses many new problems. This in itself is a stimulus to further investigation.

ORDER OF ST. JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

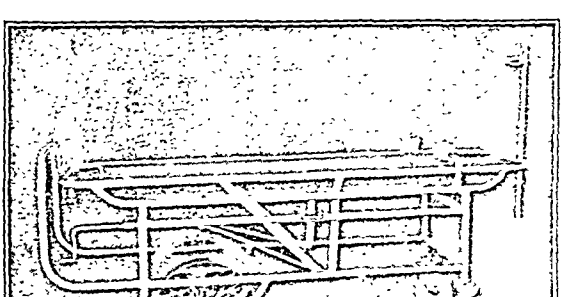
As Commanders (Brothers): Air Marshal P. C. Livingston, C.B., C.B.E., A.F.C., F.R.C.S., Sir Reginald Watson Watson-Jones, F.R.C.S., Air Vice-Marshal F. J. Murphy, C.B.E., M.B., D.P.H., K.H.S., Surgeon Rear-Admiral J. A. Maxwell, C.V.O., C.B.E., M.B., F.R.C.S. *As Officers (Brothers):* Lieutenant-Colonel K. G. W. Saunders, O.B.E., F.R.C.S., Major J. R. Hamerton, R.A.M.C., T.A., Surgeon Rear-Admirals O. D. Brownfield, C.B., O.B.E., M.B., K.H.P., and K. A. I. MacKenzie, Surgeon Captain D. Duncan, O.B.E., M.D., D.P.H., R.N., Wing Commander R. L. Soper, M.R.C.S., L.R.C.P., Drs. A. P. Gorham, R. A. P. Gray, W. J. Vickers, J. McCausland, A. Critien, O.B.E., F. J. H. Crawford, W. G. Evans, A. G. Smith, and W. E. Hutchinson, Mr. J. A. E. M. Hadley, M.B., F.R.C.S. *As Associate Officers (Brothers):* Lieutenant-Colonels A. S. Garewal, M.B., and B. S. Nat, M.D., F.R.C.S., Drs. K. V. Adalja, M.B.E., and Shin Lok Shang. *As Officers (Sisters):* Dr. Mary A. C. Ainscow and Lady Elizabeth M. Wakeley, M.B. *As Serving Brothers:* Surgeon Commanders J. L. S. Coulter, D.S.C., M.R.C.S., L.R.C.P., and W. V. Beach, F.R.C.S., R.N., Drs. A. McK. Fleming, M.C., J. J. Giraldi, O.B.E., F. H. P. Wills, J. D. McVean, G. N. Stathers, D. A. Brigg, F. C. Miller, G. I. Griffiths, J. G. Macqueen, W. G. Smith, E. J. Williams, and P. W. Rice. *As Associate Serving Brothers:* Drs. M. I. Chaudhri and M. D. Gautama. *As Serving Sister:* Dr. Eleanor D. Blunt.

Nova et Vetera

THE MIRACLES OF GEORGE FOX

George Fox's "Book of Miracles." Edited with an introduction and notes by Henry J. Cadbury. With foreword by Rufus M. Jones. (Pp. 162; illustrated. 21s.) Cambridge: The University Press. 1948.

This book is a reconstruction from the *Catalogue of all Papers and Books written by George Fox* of the 150 miracles performed by him and recorded in his *Book of Miracles*—a book which was never published and has since been lost. The *Catalogue* cites only the first and last few words of the account of each miracle, but Mr. Cadbury by patient and extensive research has identified many of the sufferers who were thus treated and the nature of their cures. The book was not issued with Fox's *Journals* because of the accusations harmful to Quakerism which might have been caused by it. In 1656 a critic wrote of the Quakers: "They pretend to learn modesty from the example of Christ, who forbad the reporting of many of his miracles to the world; but they make no little use of them among their seduced ones to confirm them thereby in their delusions, and it is not unlikely would make them more publick to the world were it not that they feared to be found liars if they should do so." George Fox's miracles do not appear to be more surprising than the medical cures recounted by contemporary orthodox physicians; sometimes they arose from the provision of spiritual consolation, now and again by the use of physical remedies. Disciples of Dick Read will find in this book an early account of painless childbirth. On Sept. 9, 1657, Thomas Salthouse wrote, "This day I came about 30 miles to Walter Clements' house who is at liberty and well. And this very hour, being about the seventh hour at night, is Walter Clements' wife delivered of a daughter by the mighty power of the Lord. Before she travailed she brought forth to the astonishment of the heathen that cannot believe and to the praise and honour of Him that hath taken away the curse. . . ."



"A miracle," said a character in Bernard Shaw's *St. Joan*, "is an event which creates faith." This definition reversed supplies the modern explanation of the miracle, itself created by faith. The miracles of George Fox are the minor seventeenth-century decorations of a remarkable personality whose spiritual odyssey is set out in his *Journal*. The book under review is of no more than antiquarian interest, but the *Journal* is one of the great English autobiographies.

Preparations and Appliances

TILTING TROLLEY FOR CONVEYING PATIENTS TO AND FROM OPERATING THEATRE

Mr. MICHAEL C. OLDFIELD, F.R.C.S., honorary assistant surgeon, Leeds General Infirmary, writes: Many of the trolleys used to convey patients to and from the operating theatre are unnecessarily primitive. Patients are often roused from their "premedication slumber" by the rude jolting they receive on the way to the theatre. After an operation under spinal analgesia, or if the patient is suffering from shock, it is a great advantage to be able to convey him to the ward with his feet raised and his head down. The trolley here illustrated has given satisfaction on these and other points. It is made of 1¼-in. (3.3-cm.) welded steel, the thrusting part consisting of

1¼ × ¼ in. (3.3 × 0.6 cm.) mild steel. At the rear end it has two fixed pneumatic-tyred wheels, and at the front end two spring-loaded castors, ensuring freedom from jolt and providing ease in steering. The tray is of 16 G. aluminium and is "dished" to the depth of 2¼ in. (5.6 cm.). A pole serves to carry the transfusion or infusion bottle, which is held in position by a stainless-steel clip. This pole is telescopic, so that its height can be adjusted when a patient has to be taken through a doorway or into a lift; and it can be fitted at either end of the trolley for leg or arm transfusion. The mechanism for tilting is stable and also adjustable, and when the tilt is in use adequately padded shoulder supports prevent the patient from sliding head first off the trolley. When the patient is lifted on to the trolley and when a tilt is not being used the shoulder rests can be turned away over the sides of the trolley.

The trolley is made by Messrs. Siddall and Hilton, Ltd., Sowerby Bridge, Yorkshire.

Correspondence

Caesarean Section

SIR,—There is no doubt that the paper read by Mr. C. McIntosh Marshall at the twelfth British Congress of Obstetrics and Gynaecology (reported in your issue of July 16, p. 147) on this subject was an excellent one, and that his results were magnificent. But unfortunately the modern caesarean section combined with penicillin and the sulphonamides makes it all appear too easy. In skilled hands there should be practically no mortality: in unskilled, the mortality will be high, and the unskilled will attempt it. That is why I suggested, not cynically, that normal labour would be an excellent subject for discussion at some future Congress.

The difficulty of knowing whether a case of slight disproportion or inertia will terminate with a live birth is great, and this knowledge can be obtained only by constant attendance in labour wards where the course of labour can be watched. Marshall made it clear that he did not advocate mass caesarean section, but I still feel that the *furor operativus* is being instilled too much in the minds of the young obstetrician.—I am, etc.,

Dublin. BETHEL SOLOMONS.

Peptic Ulcer and Smoking

SIR,—Your report (July 9, p. 78) of the discussion on peptic ulcer in the joint meeting of the Sections of Medicine and Surgery at Harrogate quotes me as saying that controlled American experiments[1] showed the importance of nicotine in ulcer production. This is not quite accurate. These experiments give a formal statistical proof, based on an adequately designed trial, of the importance of nicotine in preventing healing and in producing relapses, and my own experience confirms this. Curiously enough, the available evidence, for what it is worth, is rather against tobacco being responsible for the first development of an ulcer.

There is no proof that prolonged or repeated functional disturbances of digestion such as are produced by worry or nicotine lead to peptic ulcers. On the contrary, ulcers often form suddenly in persons with previously good digestions, while if a man manages to go six months with a bad digestion without getting an ulcer he can probably go six years or indefinitely without getting one. With a quiescent ulcer, however, the situation is different. Functional disturbances of digestion, whether due to worry, depression, irritative aperients, unwise mixtures of food or alcohol, or tobacco, can all lead to acute inflammation of the ulcer with an increase in size and an exacerbation of symptoms.

Blunderbuss prohibitions, like blunderbuss prescribing, are particularly objectionable in the management of patients with peptic ulcer; in these, extensive treatment carried on for several years is far more important than intensive treatment over a few weeks. Cutting tobacco consumption down from 15 cigarettes a day to three or four rarely makes much difference. In fact it may make an irritable, tense patient rather worse. It is better to warn the patient that he will be asked to stop smoking completely unless the ulcer is radiologically healed within a few months, but that he will be allowed to start again if complete abstinence does not cure him in a further six months.

If complete abstinence from tobacco does lead to an ulcer healing after all other measures have failed, it is probably unwise for the patient ever to start smoking again. It is one of the most dramatic things which one sees in medicine, when the patient who has refused to give up smoking for several years and whose weight has fluctuated between 9 and 10 stone (56.7–63 kg.) gives abstinence a trial, puts on 20 lb. (9 kg.) in weight within a few months, and at last loses his ulcer crater.—I am, etc.,

London, E.1. DENYS A. JENNINGS.

Syringes

SIR,—Dr. A. G. Rickard's account (July 16, p. 135) of a hospital syringe service prompts me to describe a similar service in general practice which we have now been running for two years. We are a partnership of four doctors, and, while we may have initiated the idea, the credit for experimenting with types of syringes and various packings and for maintaining the service must go to Mr. C. R. Stoffer, M.P.S. The pathology department of Chelmsford Hospital willingly carried out many bacteriological investigations.

While a few 10-ml. syringes are available for special purposes, we have found that a 2-ml. Record syringe with ceramic piston ("laminex") covers most of our daily needs, and three sizes of needles are provided, 12, 15, and 20. With the needle attached, this syringe is fitted into a good quality test-tube (5 in. × ⅝ in. = 12.5 cm. × 1.6 cm.) up to the flange—a close fit being ensured with a half-inch (1.26-cm.) cuff of cellulose wadding. The whole is now put into a cylindrical aluminium container, similar to those in use before the war for the dispatch of throat swabs. A plug of cotton-wool at top and bottom prevents rattling. These containers were specially made for the purpose. After sterilization the doctor has immediately available a complete, dry, sterile syringe, easily and safely carried about in bag or pocket.

Syringes are sterilized in batches in a Maw's "sterotherm," an electrical hot-air oven, at 160° C. for one hour, and remain in the oven for a further half-hour during cooling. It is stated that the variation in temperature in different parts of this oven is never more than ± 2° C. Syringes were contaminated with bacilli and spores, sterilized, and then sent for investigation on many occasions before the method was accepted as being completely efficient. Care must be taken to place the cylinders needle upwards in the sterilizer or they may drop off as a result of the varying rates of expansion of the metals.

Packing and sterilization are done by the pharmacist, but after use the syringes are returned to the surgery and our receptionist carries out a simple cleansing process. Syringes are dismantled and washed in hot water. Syringes used for injecting oily substances are first cleansed in a little ether. Each syringe is then washed out in industrial spirit and completely dried—a strip of one-inch (2.5-cm.) bandage and a glass rod easily dries the inside of the barrel. Care is taken to replace the right piston in the right barrel. Replaced in the cylinder, they are transferred to the pharmacist. We have had no trouble with syringe markings; syringes over one year old are still quite clearly marked.

On an average we use about 20 syringes each day, and a stock of 80 provides an ample supply of sterile syringes. Breakages are due to (*a*) accident, and (*b*) failure to return syringes promptly for cleansing, when the piston is found to have stuck and forcible attempts to free it result in a broken barrel. We have had no casualties from the sterilization process.

With the steady increase in injection therapy the provision of a sterile syringe is a daily problem for the general practitioner. The cost of apparatus and the time and work involved in the process is probably more than the single practitioner can stand, but by combining into small groups they can themselves, or with the co-operation of their local pharmacist, institute a service similar to the one described above, and save a great deal of time on their rounds and in their consulting-rooms.—I am, etc.,

Witham, Essex. T. G. BENJAMIN.

SIR,—I am glad that Dr. A. G. Rickards (July 16, p. 135) has stated many of the requirements for a good syringe. The type of syringe with metal plunger which is in common use in this country is certainly a horribly inefficient affair, and it is amazing that it survives. I am surprised, however, that he makes no reference to the type of needle fitting. Of the two generally used, the Record and Luer, the Luer is larger and far more efficient at making an absolutely air-tight joint. In a procedure such as exchange transfusion in an infant, where a syringe and two-way taps are involved, an apparatus

ade up with Record fittings is almost never air-tight, whereas ith Luer fittings this is easily attained.

The second advantage of the Luer fitting is that the stouter ozzle makes it possible for an all-glass syringe to be strong ough to stand up to routine use, and I have had to discard w syringes for chipped or broken nozzles. The glass nozzle a distinct help in venipuncture, since a trace of aspirated ood is visible.

I would make a plea that there should be a gradual change er to the Luer fitting for all apparatus. This would also ake British and American apparatus interchangeable, since is fitting has long been standard in the U.S.A. The standard pe of syringe should therefore be all-glass, with Luer fitting id (except in the smallest sizes) with eccentric nozzle.—am, etc.,

Cambridge. DOUGLAS GAIRDNER.

Ovarian Hilus Cells

SIR,—It would seem probable that the cells described in e ovary by Mr. Wilfred Shaw and Dr. Burjor Dastur (July 16, 113) are the same as those which have recently been described W. H. Sternberg (*Amer. J. Path.*, 1949, 25, 493) under the ame "ovarian hilus cells." According to Sternberg, these lls are likely to be found in all ovaries if enough sections e cut. They resemble the Leydig cells of the testicle, and eir cytology varies. In size they are usually 14 to 25 μ in ameter, and in shape they may resemble fibroblasts, may be ongated, polygonal, or oval, or may be multinucleated. They ay contain fat vacuoles, lipochrome pigment, or crystalloids Reinke. They are found in clusters of various sizes, usually the neighbourhood of vessels and nerves. They probably roduce androgens, and cases with masculinization associated ith hyperplasia and tumours of these cells are described.—am, etc.,

Hull. A. J. SHILLITOE.

*** In a letter published in last week's *Journal* (p. 230) Mr. Wilfred Shaw and Dr. Burjor Dastur stated, "We believe that ternberg's paper is the first full description of the cells written English."—ED., *B.M.J.*

The Lock Hospital

SIR,—It would be regrettable if the threatened closure of the ock Hospital were carried into effect. The venereal diseases, or the treatment of which the hospital was originally founded id which work it has done uncommonly well for so many ears, are still with us—even in greater numbers than before ie late war. There is need for more knowledge of these iseases among practitioners, so that we should increase rather an reduce the number of hospitals and clinics at which such nowledge can be acquired.

The late Sir William Osler in his famous Lettsomiam Oration eported in the *Journal*, 1917, 1, 694) at the Medical Society London in 1917 on "The Campaign against Venereal isease," said, "Venereal disease is and remains the despair the statistician. Trustworthy data are not forthcoming. ven in death a stigma is associated with it, and the returns are erywhere but under the special caption of the disease itself." o-day, more than 30 years after Osler made this indictment, s statements are substantially true. To my knowledge several en whose children had been treated in my clinic for con-nital syphilis died from syphilitic cardiovascular disease, yet e word syphilis appeared nowhere in the death records. ecently a former patient of mine consulted a cardiologist hom he misled by denying that he had ever suffered from nereal disease, though actually I had previously treated him id his wife and children for syphilis. Instances such as these rve to show that enlightenment of the public and, one may ld too, of the profession is very necessary, and the more ntres we have for instruction in and the treatment of venereal seases the better for the community.

It might be said that such hospitals and centres are becoming ndundant owing to improvements in the methods of treatment. his may prove to be an illusion, for some of us can remember ow, with the introduction of "606," it was hoped that a single large dose—the *therapia sterilisans magna* of Ehrlich—would cure a case of syphilis. We subsequently learnt otherwise. It will take 10 years, possible 20 or even 30 years, before we can say with any degree of certainty that penicillin can cure human acquired or congenital syphilis or that it can with certainty prevent the antenatal infection of the infant. Meanwhile the patients need to be kept under observation, and in my opinion there is no better institution than the Lock Hospital for the humane, painstaking, and altogether efficient treatment of the venereal-disease patient and for the dissemination of knowledge concerning these diseases. Syphilis is a much more serious and killing disease than is realized at the present day, and I would exhort the authorities to think again before deciding upon the closure of the "Lock" to venereal diseases.—I am, etc.,

London, N.12. DAVID NABARRO.

Aetiology of Infantile Enteritis

SIR,—Your leading article (July 16, p. 141) draws attention to the fact that serologically identical strains of *Bact. coli* have now been found in a number of different outbreaks of infantile gastro-enteritis. It is important to stress that in these series, as in the original series reported by Bray[1] in 1945 and by Bray and Beavan[2] in 1948, there has been a high percentage of serious cases and, compared with many previous writers, a much less definite association with parenteral *infection*.

My own feeling is that we are at last establishing one common type of severe infantile gastro-enteritis as a disease *sui generis*. This is supported by the fact that we have found identical agglutinable strains in a high percentage of some 60 severe cases which have been admitted in the past year to two hospitals at Chester and Central Wirral. In two instances epidemics of 6 cases have followed the unwitting introduction of an infant infected with an identical strain among infants suffering from other conditions than enteritis.

I feel that there is now sufficient evidence to enable us to institute certain prophylactic measures I would suggest that all infants admitted to institutions should have their stools examined for these strains, and that they should be separated as potentially infected until this is done. It would also seem to be a wise precaution to examine the stools of all pregnant women before delivery, and nursing staffs in maternity departments and sick infants' wards.—I am, etc.,

Tuberculous Empyema

SIR,—I should like to add a note to the quotation from my paper on pleurisy with effusion during pneumothorax therapy (*Amer. Rev. Tuberc.*, 1948, 57, 598) reported in a leading article in the *Journal* of July 2 (p. 23). The quotation was taken from the conclusions reported at the end of the paper. It should be noted that 90% of the twenty-one empyemata developed slowly from serous effusions and did not rapidly follow the rupture of a tension cavity into the pleural space.

Empyemata developing from serous effusions can frequently be controlled by repeated aspirations, but those following cavity rupture can rarely be treated medically with success. Thoracoplasty, if possible, should be undertaken much earlier in the latter type, but an expectant attitude will in the former type spare some patients the necessity of having major surgical treatment, the underlying disease in the lung having become quiescent following the temporary collapse. Salkin and Cadden (*J. thorac. Surg.*, 1941, 11, 109) reported that 50 of 225 empyemata were controlled by repeated aspirations.

I should like nothing I have said in my original article to influence anyone to revert to the disastrous practice of using thoracoplasty so late in treatment that it was, in fact, a desperate terminal remedy. Andersen (July 2, p. 6) expresses a similar view in his paper.—I am, etc.,

Abergele, N. Wales. JOHN B. MORRISON.

Rheumatoid Arthritis as a Psychological Disorder

SIR,—In your leading article (July 23, p. 221) entitled "New Problems in Rheumatism" you state, "Some physicians have considered that rheumatoid arthritis is a psychological disorder. The results of clinical tests with cortisone, during which any possible psychological effect was carefully eliminated by giving control substances for certain periods—with relapse in each instance—has disproved this theory."

Such a statement is surely somewhat facile and likely to be misleading, for it takes an altogether too superficial view of the psychogenesis of disease. The effectiveness of cortisone in rheumatoid arthritis in fact goes some way in support of the work of Selye[1] and the evidence of others he compounded in his conception of the "general adaptation syndrome." In this work he recognizes the potentiality of emotional stress at least as one of the causes of the syndrome.—I am, etc.,

Concussion and Hypertension

SIR,—My remarks in the discussion on head injuries were inadequately reported in the summary of the Proceedings of the Sections of Surgery and Neurology and Psychiatry at the Annual Meeting of the B.M.A. at Harrogate (July 16, p. 164). A short résumé of what I said is as follows. Eighty-three per cent of severe cases of post-concussional syndrome examined had a blood pressure higher than the standard of their age. Seventy-eight per cent of 33 men submitted to the CO_2 inhalation test proved to be hyper-reactors. The hypertension develops several weeks or months after the trauma, and appears to be a permanent sign, with a tendency to increase. The hypertension is neurogenic and is probably caused by a lesion of the hypothalamus or the medulla oblongata. Since the symptoms of the post-concussional syndrome and of hypertension are similar, it is likely that headache, giddiness, etc., after concussion are caused frequently by hypertension. The therapy should therefore be directed towards combating the latter. Hypertension and hyper-reactivity are often the only objective signs of the post-concussional syndrome, and have, therefore, a diagnostic and prognostic value.

In contrast to the hypertension, which is a late sequel, I found that the increased permeability of the blood–brain barrier, as shown by the fuchsin and fluorescein tests, is manifest only in the acute stage of concussion.—I am, etc.,

Influenzal Meningitis Treated by Penicillin

SIR,—Influenzal meningitis being comparatively common, and streptomycin not being readily available, the demonstration of its successful treatment with penicillin is of great importance. The article by Drs. Frances Braid and R. B. Meyer (July 2, p. 11) prompts me to report this case, which was very severe and recovered completely following penicillin treatment.

An infant, 7 months old, had been ill for three weeks before admission to hospital (refusing food, feverishness, loss of weight). Two weeks before admission weakness of left arm and leg, twitchings of face, and repeated vomiting occurred. She was treated with sulphathiazole by her own doctor and sent to hospital on Dec. 7, 1948. She was then listless, but resented examination. There was no obvious neck rigidity. The anterior fontanelle was tense and bulging, and the cranial sutures were separated widely. Temperature was 100° F. (37.8° C.). Lumbar puncture showed purulent fluid with numerous *H. influenzae*.

Some streptomycin was then available, and it was used as follows: intrathecally, 50 mg. on the first day and 25 mg. on subsequent days; intramuscularly 20 mg. per lb. (0.45 kg.) of body weight daily. On second, third, and fourth day of treatment the spinal fluid was sterile. On the fifth day the fluid contained many *H. influenzae* with well-marked pleomorphism. At this stage it was assumed that the organism had become resistant to streptomycin (actually it was later found that the *H. influenzae*, which was of a Pitman type B, was sensitive to streptomycin and also to penicillin in concentration of 20 i.u. per ml.). Penicillin treatment was started with 40,000 units daily intrathecally and 120,000 units intramuscularly 3-hourly. Sulphadiazine (1 g. 4-hourly) was also given. The spinal fluid became sterile after 24 hours and remained so. After nine days the intrathecal treatment (which was mainly done by puncture of the lateral ventricles) was discontinued, and several spinal-fluid samples remained sterile. Systemic treatment was discontinued on the 19th day of treatment. By this time the child was very well and eating and behaving normally. The hydrocephalus, which had been very marked, was hardly apparent.

She has been seen regularly for five months and seems perfectly normal, and even advanced, for her age. She is now 13 months old, can walk fairly well, understands many words, and seems very bright and intelligent.

—I am, etc.,

E. T. BASSADONE.

London, S.E.10.

The Children Act

SIR,—Belatedly, and with great astonishment, I learn that under the Children Act, 1948, responsibility for the needs of children deprived of normal home life is vested in the Home Office, and that local authorities are to set up *ad hoc* committees and appoint children's officers. Britain used to lead the world in hygiene, but if the care of children, and especially those in question, is not the prime concern of the health authorities, then my conception of health and hygiene, including mental hygiene, must be wide astray. The Home Office certainly has an alluring title.—I am, etc.,

JOHN DALE,
Medical Officer of Health.

Melbourne.

The Triumphs of Psychotherapy

SIR,—I have just read the paragraph (July 2, p. 37) dealing with the most inspiring service held in Canterbury Cathedral on June 25, at which I was privileged to be present. One hesitates to question the pronouncement of a president of one of the Royal Colleges, but I feel that Lord Moran's statement, that when physicians had tried to follow the workings of the mind and its many aberrations he could tell of no comparable triumph as had been shown in dealing with disease of the body, cannot go unchallenged.

It is true that psychiatry is a young science and that there are many schools of psychological thought. But surely the very striking successes resulting from carefully arranged electric convulsion treatment and insulin-shock therapy in various forms of neuroses and psychoses, and more recently the benefit derived from prefrontal leucotomy in wisely selected cases, are veritable triumphs in the psychiatric realm. It would be very instructive to know what Lord Moran had in mind when he made this rather pessimistic statement. One does feel that considerable advances in psychotherapy will take place in the fairly near future, and that the outlook is not as black as the learned President has suggested in what was a very masterly address that should be very carefully pondered by all thoughtful people.—I am, etc.,

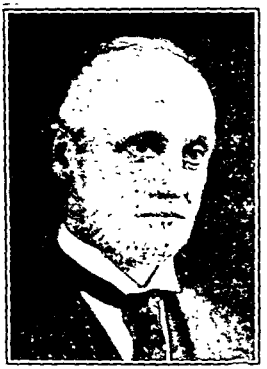
J. B. GURNEY SMITH.

Epsom, Surrey.

POINTS FROM LETTERS

The Medical Directory

The editor of the *Medical Directory* writes: To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request. The full names of the doctor should be sent for identification.



Prefrontal Leucotomy Incision

Dr. A. P. BERTWISTLE (Birmingham) writes: Why is the incision for prefrontal leucotomy made vertically? Nothing could be more obvious, particularly when bilateral. A somewhat longer incision made along the creases of the forehead would hardly be noticed, especially as part would be through the scalp. The superficial temporal artery could easily be drawn aside or ligated. That important landmark, the coronal suture, would be easier to find. The temporal muscle would, of course, be split in the line of its fibres. . . .

Obituary

RICHARD WALTER MARSDEN, M.D., F.R.C.P., D.P.H.

Dr. R. W. Marsden died at his home in Manchester on July 10 at the age of 81. He qualified with the Conjoint Diploma at Manchester University in 1891, taking the degree of M.B., Ch.B. a year later, after a distinguished undergraduate career, and proceeded M.D. in 1896. He took the D.P.H. in 1898. His ambition was to practise as a consultant, and he soon established a considerable reputation for his clinical acumen, especially in diseases of the chest. During this early period he became medical superintendent of the Monsall Hospital for Infectious Diseases, and university lecturer in that subject. Those who attended his classes speak of him as a dramatic teacher. Later he was appointed university lecturer in tuberculosis, and an honorary physician at Ancoats Hospital, Manchester.

In 1906 he became medical officer and in 1927 medical superintendent of Crumpsall Hospital, Manchester, and there he did his most important life's work. His association with this hospital began in 1892 as resident medical officer, and he could recall vividly the state of affairs in a poor-law hospital at that time, a story that illustrated the progress made in hospital work during the last half-century. In describing the history of Crumpsall Hospital from 1906 until he retired in 1933, Dr. Marsden modestly gave most of the credit to others, but those who knew him and his work for the hospital realized how much his foresight and strength of character did to raise it from a nineteenth-century poor-law hospital to a busy general hospital of high status and a first-class training school for nurses. He will long be remembered there with affection and esteem.

He was a good administrator, never afraid to face awkward problems, and he detested humbug. But first and foremost he was a physician of outstanding merit who relied on accurate clinical observation. Generations of residents who came under his wing have cause to remember his kindly but thorough tuition, not unmixed with admonition, and his capacity for seeing the whole as well as its parts. Crumpsall Hospital under his guidance gained a high reputation not only for the care of patients but as an excellent place for young doctors to learn medicine before going into practice. His election as F.R.C.P. in 1929 was a well-earned distinction, and one not commonly given at that time to medical superintendents of municipal hospitals. He came out of retirement in 1940 to take charge of a hospital in Macclesfield, and carried on this work until 1946.

Throughout his professional career Dr. Marsden was a most active member of the local learned societies, and in 1928 was president of the Manchester Medical Society, of which he was a trustee at the time of his death. A member of the B.M.A. since 1895, he was honorary secretary of the Section of Diseases of Children at the Annual Meeting of the Association at Manchester in 1902. In his younger days he was a good athlete, being specially proficient at gymnastics and swimming, and in later years a keen golfer.

Manchester medicine has lost a memorable and much-loved figure. He is survived by his three sons, all members of the medical profession, and by his second wife. His first wife, the mother of his family, died in 1936.

DOUGLAS EDWARD FINLAY, M.B., B.S.

Dr. Douglas Edward Finlay died at his home in Gloucester on July 10 after a long period of ill-health. He received his medical education at St. Mary's Hospital, London, and qualified in 1902, taking the London degree in 1905. After being house-surgeon at the Gloucestershire Royal Infirmary, he joined its honorary staff as assistant physician and settled in private practice in Gloucester. He was appointed honorary physician in 1913 and senior honorary physician in 1924, which position he held for 22 years until 1946, and was also visiting physician to the Gloucester City General Hospital. During the war of 1914–18 he served in France as a Territorial with the rank of major, and was mentioned in dispatches.

A member of the B.M.A. since 1903, he was honorary secretary of the Gloucestershire Branch from 1908 to 1916, and during that period played a notable part in the controversies over the National Health Insurance Act. He was president of his Branch in 1920, served for two periods on the Council (1912–14 and 1925–31), and was on the Journal Committee from 1925 to 1927; he was a representative from 1919 to 1924. Finlay had many interests outside his profession. As a member of the Gloucester City Council and, later, as mayor in 1926–7, alderman, and justice of the peace, he rendered much public service. His special interest in education was shown by his many years of work as chairman of the education committee, chairman of the United Schools' Governors, a lecturer to the Gloucestershire College of Domestic Science, and an examiner for the General Nursing Council. He also took an active interest in a number of learned societies, and was a Fellow of the Royal Geographical Society, the Royal Archaeological Society, and the Royal Society of Arts. Many and diverse pursuits engaged his enthusiasm, and he contributed to each a knowledge and sagacity which commanded respect.

As a physician Finlay was outstanding and had those inborn qualities of mind which make the great clinician. He loved medicine, reading extensively and pondering on its problems, and contributed to this *Journal* several notes on cases of unusual interest. To present him with a clinical problem was to be welcomed as a kindred spirit. His reputation as a consultant was high. In grave crises his presence imparted, to doctor and patient alike, a calm confidence which was remarkable. Yet it cannot be said that he devoted himself arduously to the practice of medicine. Often he was busy with political, educational, and other interests. It seemed as if all these activities, as well as the practice of medicine, were to him so many hobbies to be followed in turn as his mood dictated. But once a problem was presented to him, Finlay's friendly response, immediate interest, and readiness to help were completely disarming. He was a colleague truly loved.

He is survived by three daughters and two sons, to whom great sympathy will be extended.

The British Red Cross Society has issued its Annual Report for 1948. It gives a full account of the Society's activities during the year at home and abroad, and is obtainable (price 2s 6d.) from the Society at 14, Grosvenor Crescent, London S.W.1.

Medico-Legal

THE HAIGH TRIAL

MEDICAL EVIDENCE

[FROM OUR CORRESPONDENT]

At Lewes Assizes, before Mr. Justice Humphreys, on July 18 and 19, the trial took place of John George Haigh on a charge of murdering on Feb. 18 Mrs. Olivia Durand-Deacon, of Onslow Court Hotel, South Kensington. The Attorney-General (Sir Hartley Shawcross, K.C., M.P.), Mr. Eric Neve, K.C., and Mr. Gerald Howard appeared on behalf of the prosecution, and Sir David Maxwell Fyfe, K.C., M.P., Mr. G. F. R. Morris, and Mr. David Neve on behalf of the defence. The prisoner pleaded "Not guilty," but later this plea was amended to "Guilty of the acts charged, but insane at the time they were committed." Nearly 30 witnesses were called for the prosecution, and only one—a psychiatrist—for the defence. The circumstances of the murder and the disposal of the body of the victim have been given in such detail in the public press that it is unnecessary to repeat them here, and this report is confined to the evidence of the medical witnesses. After the two-day hearing the jury took only 14 minutes to arrive at a verdict of "Guilty," and the prisoner was sentenced to death.

Medical Evidence for the Prosecution

Dr. C. Keith Simpson, pathologist, Guy's Hospital, and lecturer in forensic medicine, University of London, said that on March 1 he had visited premises at Crawley known as Giles Yard, and on the wall of a workshop belonging to Hurstlea Products Limited he noticed, between two windows, a group of finely spattered blood-stains. Soil was lifted from the yard to a depth of about 3 in. over a considerable area, and a quantity of soil amounting to 575 lb. or thereabouts was taken away; it was later shown to him at New Scotland Yard by Chief Inspector Mahon. On March 2, 3, and 4 this was examined by him in the presence of Dr. Holden, director of the Metropolitan Police Laboratory, and in it were found, among other articles, intact upper and lower dentures and various human remains, including gall-stones and bony parts. Asked whether, from his examination, he concluded that a human body had been dissolved in sulphuric acid, Dr. Keith Simpson replied, "Yes, they represented part of one human body."

The Attorney-General: Was there anything to indicate that more than one body had been dissolved?—No, I found nothing.

Was there any indication at all of the sex?—Yes, one of the bones of the hip having sex characteristics was still partly preserved and was plainly, in my view, female.

Was there anything to indicate the probable age of the female whose body had been so destroyed?—I came to the conclusion that such as remained of the better-preserved bones were fragile and showed senile changes. I should say, I think, that the bones were those of an elderly woman—but no further; not more closely.

Asked if the remains gave any indication of the cause of death, witness replied "No," neither was any natural disease detected. There was no doubt that immersion of a body in concentrated sulphuric acid would in certain circumstances result in destruction of that body as indicated by the remains which had been found. Plastic substances, such as the handbag and dentures, would resist erosion, as would body fats and, for instance, gall-stones.

He formed the view that the blood splashes found on the wall could have got there if a person standing on the bench between the two windows had been shot through the head from behind. A pad of cotton-wool could be used to limit the flow of blood from the entry and exit holes of the bullet.

There was no cross-examination.

Miss Helen Patricia Mayo, dental surgeon, of New Cavendish Street, London, identified the dentures found at Crawley as having been supplied by her to Mrs. Durand-Deacon, a patient of hers, in 1947. Asked if she was certain of that, she replied, "I could describe them from my notes before I saw them." They had certain peculiarities which established their ownership beyond doubt.

Dr. Henry Holden, director of the Metropolitan Police Laboratory, New Scotland Yard, said that on Feb. 28 he had received from Inspector Symes a fur coat and a bag; the sleeves of the coat were patched and from the bag there had been recovered portions of fibre which had come from the coat.

Having produced sundry other exhibits, the witness said that he had received from Dr. Keith Simpson half a gall-stone. There was human blood on the gas-mask case and rubber apron already produced; these stains were associated with odd fibres of beech wood. A partly corroded rod which had been produced was also of beech wood, the fibres of which might have been deposited on the apron. There were also human blood scrapings on the apron. Comparatively recent small, but obvious, blood-stains were found on the blue shirt produced. The various constituent parts of the handbag produced, in his opinion, had formed one bag which had been immersed in sulphuric acid; the stitches had rotted and the bag had fallen to pieces. The gall-stone was human, having given a reaction to human protein. A small patch of human blood had been found at the junction of the collar, on the back of the neck of the fur coat.

Shown a penknife, and asked if there had been any considerable quantity of blood on it, the witness replied, "No, the merest traces, but they were human." It was not possible to tell the age of the person from whom the blood had come.

Dr. George Edgar Turfitt, deputy director of the Metropolitan Police Laboratory, said that on March 1 he received from Det. Insp. Symes a revolver which was in proper working order: on the inside of the barrel there was a quantity of unburned powder which, together with the fact that there were no signs of corrosion of the barrel, suggested that the weapon had been fired within the last week. He was also shown eight cartridges of a type which could have been used in such a weapon—an Enfield revolver. Other exhibits were identified and stated to have been attacked by concentrated sulphuric acid. A mackintosh and rubber apron contained a residue of sulphuric acid and animal fat, and acid residue was found on a pair of woollen gloves and a wooden rod. With Dr. Holden he had examined a quantity of earth, which he had subsequently taken away for further analysis and had found to contain, speaking generally, sulphuric acid, a high percentage of animal fat, and a certain amount of calcium and phosphate. On March 7 he had received from Dr. Holden a gall-stone which on examination proved to be "a typical gall-stone of the cholesterol type—a soft gall-stone."

Medical Evidence for the Defence

The only witness called for the defence was Dr. Henry Yellowlees, of Harley Street, physician for mental diseases, St. Thomas's Hospital, consulting psychiatrist to the British Expeditionary Force during the war. He was examined by Sir David Maxwell Fyfe.

Dealing with the accused's mental state, the witness said his first impression had been that he had very obviously what was called "a paranoid constitution." There had been no doubt about that after the first interview.

Asked upon what formative factors such a constitution depended, the witness said it was generally held to result partly from heredity and partly—perhaps even more—from environment—especially the early upbringing, home atmosphere, and experiences. In most adolescents the condition declared itself about the ages of 16 or 17, except in most unusual cases. In practical relation to paranoia, it was an essential preliminary of all the paranoid insanities. You could not suffer from any member of the group under the general description of paranoid insanities without being the possessor of a paranoid constitution—or temperament, as some people preferred to call it—which was the only soil, so far as was known, in which paranoia could develop and flourish.

Sir David: Would you deal therefore first with the medical evidence of the possession by the accused of a paranoid constitution? Would you describe that evidence as being scanty, considerable, or abundant? A. As regards the possession of the constitution, I would say the evidence was abundant and puts it beyond any question.

Q. And I think there are two lines upon which you approach that. What are those? A. The history of the patient, which I have

mentioned, and also, of course, his demeanour under examination and the many symptoms that he may show.

Q. Taking the first of those, the history: do you find here in the history what you consider to be the breeding-ground of paranoid constitution? A. Yes, the history as I have it is a most characteristic breeding-ground for the development of this constitution.

After a legal discussion upon the admissibility of evidence as to the prisoner's early home life being given by this witness, Sir David asked Dr. Yellowlees what, in his opinion, had been the religious atmosphere and surroundings of the prisoner's youth; to which the witness replied:

"I should say, sir, in view of what has been said, that every point was not actually mentioned to me by the accused; I have taken certain points which he mentioned to Dr. Matheson, and I presumed that he would mention them to me. Everything he did say to me agrees with what he said to Dr. Matheson."

Asked to confine himself, so far as possible, broadly to the information obtained from the prisoner, the witness said:

"He made it clear to me, from what he said, that he was brought up in a fanatically religious atmosphere, and he told me that newspapers and radio were forbidden in his parents' house, that friends and neighbours were excluded, and that the wrath and vengeance of God were held over his head as the punishment for every trifling misdemeanour. That, in summary, is what he told me about his home atmosphere. He told me also that his mother was greatly given to studying dreams in a future-telling sense and believed that the future could be told by them, and he told me that books upon these subjects were very readily available to him although newspapers and wireless were not."

Q. What opinion did you form as to the mental stability where you get, on the one hand, that extremely exclusive religious background and, on the other hand, this harping on and stressing the influence of dreams? Did you think that showed a heredity of mental stability, or the contrary.? A. I think any household with that atmosphere is bound to be the very reverse of stable, and in this matter of heredity it is believed and said that this is the only thing which really is transmitted—namely, a mental instability. There is no obvious thing or disease that you have got that is transmitted; it is the mental instability.

Q. I suppose that, of course, one has to distinguish heredity and early environment. That early environment must have an accumulative effect on the heredity? A. Of course, the two things are interwoven; they cannot help being.

Asked if he attached importance to the absence of friends in relation to the paranoid constitution, the witness said he attached great importance to it and would attach even more to it if it were shown that that had been carried into school-days. A great authority, the late Dr. Percy Smith, had said in a famous address, "The solitary schoolboy is the potential paranoic," a view with which he heartily agreed.

"If you have a youth of inherited nervous instability," he said, "brought up in a solitary atmosphere and with the fear that unseen and punishing powers are all around him, he tends to run away from them in the only way he can—namely, into a world of, in the first place, fantasy and fairy-tale. He will not face his difficulties fairly, and he becomes progressively less able to do so. At first he merely thinks of some clever way round, of some clever way of avoiding punishment, and if it develops further, and if there is no clever way round, he goes into himself, into a world of fantasy, and makes an imaginary solution for himself, and comes to believe in it."

Q. By coming to believe in it, does that mean he blinds himself to the practical solutions and concentrates on the fantastic solution in his own mind? A. Yes, I should not have said "believe"; he blinds himself as far as he can.

Q. From the history he has given you, do you find illustrations of the formative action in bringing about a paranoid constitution? A. Yes.

Asked if he attached importance to the change of surroundings experienced by the prisoner when, from the age of 10 to 16, he exchanged the atmosphere of the Plymouth Brethren for that of Wakefield Cathedral, the witness said:

"Yes, great importance. Here was this youth, a boy, under a form of worship in which he did not believe himself, and of which he was frightened, and he is plunged into the opposite extreme—a form of worship where ritual and mysticism hold a very much more prominent place; and by entering into that he avoids the conflict between his beliefs that he has got in his early religion and his developing mind. . . ."

Sir David said that Haigh had been a chorister at Wakefield Cathedral and subsequently, at the age of 17 or 18, assistant organist, which the witness said he had accepted as general history, not obtained from the prisoner. The witness understood that at that time the atmosphere of the cathedral was very "High Church." Taking into account the very circumscribed and harsh surroundings from which Haigh had started, the change to surroundings of that kind would have appeared to the prisoner an ideal way of escape; the prisoner might not put it in that way, but that would be the effect, and it would be harmful to the extent of encouraging the tendency to avoid reality.

Asked if Haigh had given him an account of his dreams during that period, Dr. Yellowlees said (referring to his notes by permission of the Judge) that Haigh had told him that at that time he had experienced a recurring dream which he called "The dream of the bleeding Christ," and in that dream he had said that he could see either the head, or sometimes the whole body, of Christ on the cross with blood pouring from his wounds. All along it had been the question of blood that troubled him; he had said that at that time he had been unable to understand why Christ had been left to die slowly upon the cross and had not been killed at once.

The witness accepted from Sir David that that dream had stopped at about the age of 16 and had recurred once—when he had been in Brixton prison awaiting trial—but did not know that of his own knowledge. In his experience, such dreams were invariably associated with a very large amount of waking fantasy and day-dreaming.

Asked if a person in the course of forming a paranoid constitution was secretive, the witness said that was very important; they were almost invariably secretive up to a certain stage; it was the beginning of an entirely private and almost mystic life which they treasured because it was apart from the cruel world. If one had the confidence of such a person—which was not easy—at a fairly early stage—as was indeed the case in ordinary life—the person could be induced to unburden himself, after which he often went to the other extreme and became very voluble, verbose, and garrulous. It depended upon the two persons concerned and upon the stage of the disorder.

Asked whether, as the disorder formed and the subject became more and more wrapped up in his own fantastic and personal solution to life, he formed the view, generally, that he was much cleverer than and really on a different level from ordinary people with whom he mixed, Dr. Yellowlees replied: "Yes, that is the natural point. He can only preserve his self-esteem and conceal from himself the fact that life is too much for him by making these fantastic solutions and saying, just like every person who withdraws from life, 'Look what a clever solution I have made! Oh, the cleverness of me!'"

That being the first stage, the paranoid constitution upon which was erected the foundation of the structure of the mental disorder or aberration known as paranoia, Sir David asked whether there was much or little evidence of the second stage. Dr. Yellowlees said that before answering that question he would like to deal with one or two points further concerning the paranoid constitution. A person so affected had to live two lives at once; he had, so far as he could, to keep up the appearance of being clever and to avoid his "psychological bluff" being called. "You therefore find such people," he added, "though in no way obviously insane, to be extremely vain and very conceited, very fond of showing off and taking a delight in scoring off their fellow-creatures. A large number of the false-pretences people and the confidence tricksters have got a paranoid constitution. . . . It is an abnormality but it is in no sense a disease of the mind, and it is important to remember that the constitutional paranoid has got to keep his end up with regard to the society in which he lives."

In reply to Sir David, the witness agreed that one of the greatest authorities on paranoia was Professor Tanzi, of Florence, with whom the witness had been in contact and with whose work he was acquainted. The professor's book on mental diseases, which contained a chapter on parancia, was a classic.

Sir David: I want to get it clear, Dr. Yellowlees, that paranoia is a recognized and discussed mental aberration and, if I may say so without offence, not something that you have created for this case. One wants to be quite blunt about these matters because the impression might exist. A. I am very glad you said so, sir.

Q. Dealing with that, in your view has the acute paranoid constitution, that abnormal personality that you have described, developed into the disorder known as paranoia? That is what I want you to address yourself to. A. The answer is "Yes," but—

Q. Could we just pause there for a moment, because I want to get it quite clear, if I may, in your words. I told my Lord and the jury yesterday that paranoia was a complete and permanent alteration of the entire personality which overwhelms the mental outlook, character, and conduct. Was I correct in saying that? A. You were correct, sir, but it would need, I think, some clarification.

Q. Well, will you clarify it, because counsel is apt to paint with a broad brush and I do not want there to be any mistake about it. A. I think the only essential qualification is you should say a completely well established paranoia, because paranoia, whatever else it is, is an extremely progressive disorder. You cannot say that it begins on this day and ends on that one.

Q. I quite appreciate that, Dr. Yellowlees. Putting in the word "completely"— A. Well established.

Q. "Well established paranoia." Would you say that I had put it correctly as a complete and permanent alteration of the personality overwhelming the mental outlook, character, and conduct? A. Yes, I think that is correct.

The witness said that after his second interview with the prisoner he had on the spot thought of the book which Sir David had mentioned and he had procured it, although he had not read it for 30 years, and he had found that the statements made in the book, which was regarded as a classic, and the matters which he had himself elicited had seemed so startlingly in harmony that he had felt it his duty to say so. The point where a man with the paranoid constitution developed into a paranoic was terribly difficult to make plain; there were varieties of paranoia, and the most important one for his purpose happened to be one of the most rare and terrible of the whole group.

"The word is sometimes used loosely among medical men," he added, "but if you ask a medical man what he means by a pure paranoia he will understand that you are talking about a condition of which this Professor Tanzi's is the classic description, and a very rare condition. It is technically called—I am sorry about this—one of the egocentric paranoias, and it is called 'ambitious' or sometimes 'mystical,' and the point at which it develops, so far as it can be a point, is when the patient's fantasy world becomes really his psychological home, where it becomes more real to him than his real world, and when his fantastic solution and his idea of personal cleverness passes all bounds and he regards himself as nearly as possible omnipotent. All his other activities, his work, his sexual activities, and so forth, are ignored and the energy that ought to go into them is turned into building up this fantastic life. Usually he does not get to the length—except in a very long-standing case—of regarding himself as a god, although I have met patients who did. Usually he stops short of that and regards himself as in mystical communion with some force or principle or outside power which guides him. I believe that the process has begun in this case. I cannot tell you how far it has gone."

Asked for his reasons for considering that the patient had passed from the "constitutional" stage into that form of insanity, from the medical point of view, Dr. Yellowlees said that was a difficult matter to deal with, because one of the very important grounds for his opinion was his lifelong experience and familiarity with patients of that kind, but there was first his conviction that the prisoner had a paranoid constitution in a high degree; then came a series of points which had a very cumulative effect taken together: to begin with, there was the very strong indication of a progressive development of a system of mystical ideas expressed with intelligence and lucidity but ever less related to the morals of ordinary society and ever more associated with reference to some vague force or principle under whose guidance he acted.

Sir David: Would you tell us what he gave as the first actual conscious revelation? A. He stated to me that his first conscious revelation took place towards the close of the period at Wakefield when he was 16 or 17, he said, and he was divinely guided to interpret a verse in the Old Testament as an instruction to drink his own urine, and it is a matter of fact that I understand he has consistently followed that instruction to this day, and he was certainly doing it when I saw him.

Q. Just pausing there for a moment, is it an accepted characteristic of paranoia that paranoics do follow what are well-known customs among primitive and savage tribes without knowing that they are following primitive customs? A. That is true. I should not have associated it with this particular act, because it is not altogether uncommon among mentally unstable and peculiar persons, but it may well be as you say, and it certainly is a fact that paranoics in general are really, though they do not know it, throw-backs; they are following the customs of primitive and savage peoples.

Mr. Justice Humphreys: They are what?

Sir David: "Throw-backs" was the word he used, my lord.

The witness: Atavisms. Would you quote Profession Tanzi in support of what I have just said about atavisms, to show it is not my own invention?

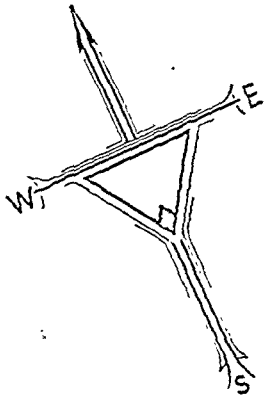
Sir David: Well, I think my learned friend has a copy of Tanzi and he can check on it in any way, but I think it will be enough for us if you say that that view is supported by Professor Tanzi and it is one of the characteristics that he points out, and you agree with that. A. That is so.

Q. Would you go now to the second of those points which you are emphasizing? A. Then he says that the second revelation was marked by the appearance—I think it was in 1944 or 1945—of what I call the "Tree Dream" which he described to me three or four times, always in the very same way.

Asked by Mr. Justice Humphreys to describe the dream, Dr. Yellowlees said:

"He said that it started after a motor-car accident. That may or may not have any importance: I do not know. The point is that he says that in that accident a lot of blood from a scalp wound ran into his mouth and revived his ideas about blood. I have no comment to make on that. The dream that he describes is that he goes out into a forest and sees before him an entire forest of crucifixes. These gradually turn into trees, and the trees, which have branches stretching out at right angles, appear to be dripping with dew or with rain. As he gets nearer he sees that it is blood that is dripping from the trees and not water. One of the trees then gradually assumes the shape of a man who holds a bowl or cup beneath one of the dripping trees and collects the blood which comes from it. As this happens he sees the tree get paler in colour and he himself feels that he is losing strength. Then the man in the dream, when the cup is full, approaches him and offers it to him and invites him to drink it. At first he says he is unable to move towards the man, and the man recedes and he cannot get to him; and the dream ends.

"He then tells me that this dream may be repeated for some nights in succession—once he said six or seven nights, and then again I think he said four or five—and during the time when the dream is recurring he is uneasy, distrait, able to do his daily functions all right, but not really at ease. He says that after this his killings occur and after them—after one or two of them, I think that is what he said; I am not sure—he dreams again the same dream, but this time the man does not recede from him and he is able to drink the blood."



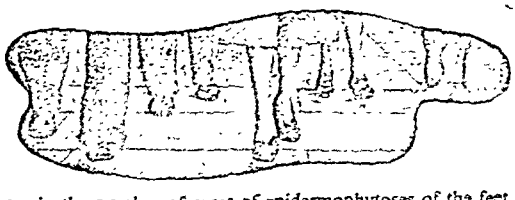
Sir David: Did he tell you whether the dreams caused, in his waking hours, a desire for human blood? A. Yes. He was not very clear about that, but he simply said he was very uneasy and felt he must do something—and that was all he said to me.

Sir David asked whether the two factors to which the witness had attached importance—the drinking of the urine and the dreams which had been described—were an end of the fantasy or was there a further fantasy which defied description as to the working of that type of mind. Dr. Yellowlees replied that it had been shown that such statements were simply attempts to express what could not possibly be put into words. Even in the telling of a dream it was not always easy to be precise, and when dealing with these mystical fantasies it was impossible.

Asked whether there was complete absence of the sex element in the accused's conduct, he said there was a complete absence of any interest or activity in sex. That in itself was an abnormal thing.

Q. This was not a case dependent, then, on the sort of Viennese psychology that everything was related to sex? A. No, it had nothing to do with that. The absence of a sex element was important, because it was a very great abnormality of some kind that a physically healthy

for children everywhere



The problem of the run-down, debilitated child is shared by medical men throughout the world . . . and the universal answer is a tonic at once restorative, formative and protective. Syrup Minadex is such a tonic, combining three distinct therapeutic groups—iron, copper and manganese for their haemopoietic properties; the glycerophosphates of calcium, sodium and potassium, traditional nerve restoratives; and vitamins A and D to promote the growth of healthy tissues. These ingredients are combined in a delicious orange-flavoured syrup, making Minadex acceptable to the most fastidious palate in the warmest climate.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX, ENGLAND

A NON-MERCURIAL FUNGICIDE FOR TINEA PEDIS

The summer season brings an increase in the number of cases of epidermophytoses of the feet (for example, athlete's foot) and similar fungal infections of the axillae and perineal regions. Chlorphenesin (*p*-chlorophenyl-α-glycerol ether), evolved in the laboratories of The British Drug Houses Ltd., is a non-mercurial fungicide which is strongly inhibitive to the growth of the causative organisms of tinea pedis and most other epidermophytoses. Chlorphenesin is issued as MYCIL Ointment and MYCIL Dusting Powder. Clinical results confirm the effectiveness of the combined application. MYCIL Dusting Powder is particularly useful as a preventive against re-infection when clinical cure has been obtained. Literature and samples will be forwarded on request.

MYCIL

THE INTRAVAGINAL TAMPON IN MENSTRUAL HYGIENE

An important clinical study

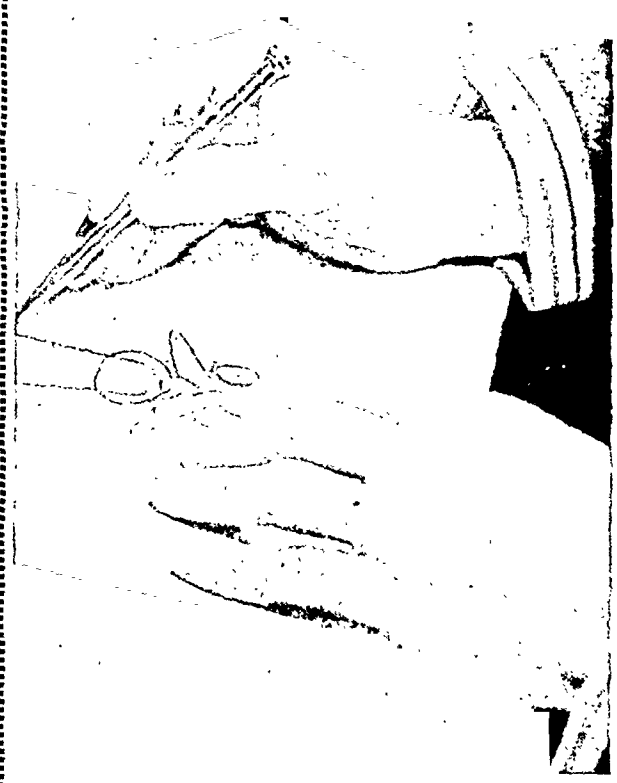
Significant facts obtained by the close observation of 25 parous and nonparous women

In view of the increasing use of the intravaginal tampon for the absorption of the menstrual flow, the following important study was undertaken to determine whether or not this method of sanitary control is safe and not prejudicial to health.

Twenty-five women—parous and nonparous—were selected and were under daily institutional observation during two successive catamenial periods. Ranging in age from twenty-one to forty-five, some had previously used tampons, others had not.

The following summary indicates clearly the findings of the study.

Reprinted from the Medical Record, U.S.A. for May, 1942



1. In not a single instance was there any evidence of local irritation brought about by the use of the tampons.
2. No uterine cramps, suggestive of block of the uterine flow or damming back into the tubes were reported in any case of this series.
3. No bladder irritation was reported.
4. The average number of tampons used in a period was ten.
5. In cases in which a cervical erosion was present, neither the amount of bleeding nor the character of the erosion was altered by the use of the tampons.
6. There was no appreciable difference in the bacterial flora of the vagina and cervix, as determined by smear and culture, before menstruation and after the use of the tampons during the menstrual period.
7. There was no appreciable difference in the pH of the vaginal or cervical secretions before menstruation and after the use of the tampons during the period.
8. Absolute comfort and complete absorption of the flow was obtained by the proper correlation of the size of the tampon with the length and calibre of the vagina.
9. *The evidence is conclusive that the tampon method of menstrual hygiene is safe, comfortable and not prejudicial to health.*

TAMPAX

If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

young man, who did not seem to be at all scrupulous in his actions, should have no interest whatever in sex and sexual activity. It also happened to be stated in authoritative works that that was a thing found in paranoics, who sublimated their sexual energies into that self-worship and mystical fantasies.

Asked what differentiation the accused had made between his killings and his ordinary acts of dishonesty, the witness replied that the accused had been quite normal on that subject. As to his previous convictions (all for dishonesty), he had said that the third was not proper. The first two he admitted, and had said that he had to live like anybody else; having good enough wits and rather better than his neighbours, he really had to do the best he could. He really did it to get the artistic joy of a good job. He had said he was like an artist painting a picture when he had successfully hoodwinked his fellow creatures, which was typical of an early paranoic constitution and showed the conceit and vanity which were also to be observed in petty tricksters.

Questions by the Judge

In reply to his Lordship, the witness made it clear that none of the accused's previous convictions were for any form of violence; all were concerned with dishonesty. The killings were treated entirely differently by the accused in his statements. He had objected very much to the word "murder"—"It was, I think, almost the only sign of touchiness that he showed," he added. The prisoner had not minded their being described as "killings." He had said he had no special interest in rights or wrongs or in the laws of the country or in his victims, because "This is his destiny." He had said he had a destiny to perform—and believed it. The prisoner believed that the killings were the third revelation and—although he was not yet clear about it—he thought they might have to do with eternal life, but he did not know how. He was the instrument of an outside power. Before the killings he had had no particular plan; in one case he had said he had not known until a minute before that he was going to kill the victim. On the other hand, he had stated that after the killing he had taken every possible precaution to avoid detection because he knew perfectly well that murder was punishable by law and, like any other sensible man, he was anxious to avoid it.

Mr. Justice Humphreys: If I have got this right, Dr. Yellowlees, he told you he took steps to avoid detection afterwards because he knew quite well that to kill a person was a crime. A. Yes, my Lord; I think he used the phrase "punishable by law."

Q. Very well. A. And he added that of course it did not apply to him.

Q. What did not apply? A. What I have just said—that murder, being punishable by law, did not apply to him.

Q. I do not quite follow. Did he suggest that he was not amenable to the law. A. Certainly, my Lord.

Q. Why was he not amenable to law? A. Because he says that he is working under guidance and in harmony with some vital principle.

Q. And he thought if he said that everybody else would believe it? A. I would not say that, my Lord. The one thing he is not is a malingerer.

Sir David: Did he appear to you to believe? A. He appeared to believe it absolutely.

Mr. Justice Humphreys: He thinks he ought not to be punished? A. That is so.

Q. Does he really think he will not be punished, that if he is caught stealing or killing, or anything else, that he will not be punished? A. I asked him that, my Lord, and what he said was, "I am awaiting trial with complete equanimity. I am in the position of Jesus Christ before Pontius Pilate, and the only thing I have to say, if I do say anything, would be"—and he quotes, "There can be no power against me unless it were given him from above."

Sir David suggested that it was not uncommon for a murderer to show callous indifference and asked what the witness considered *unique* in the case. Dr. Yellowlees replied:

"I think the absolutely careless, cheerful, bland, almost friendly indifference of the accused to the crimes which he freely admits having committed is unique in my experience."

Asked whether he believed that accused had really had the "tree" dream, the witness replied that he thought the accused may have been exaggerating the effect that it had upon him because, as he had said, the paranoic person was very lucid and intelligent and lived in two worlds at once and here they were clashing; further, he did not think it possible that Haigh could have invented the dream.

Asked for his views on the accused's claim to have "tapped his victims and drunk their blood," the witness said he thought it was pretty certain that Haigh had tasted it; he did not know whether he had drunk it or not, and from a medical viewpoint it was not important, since blood had run through all his fantasies from childhood like a *motif* and was the core of the paranoic structure which he believed Haigh had erected.

He agreed, having seen many papers and statements written by the prisoner, that Haigh's writings were consistent with his being in a state of paranoia.

The witness said he was not prepared to pass an opinion on the legal test as to whether Haigh knew that what he was doing was wrong. The prisoner had gone "over the borderline" from possessing a paranoid constitution to being in a state of paranoia, but as to the extent to which that had occurred witness could not speak with the same definiteness.

Asked what contact and opportunities for observation would be necessary for a psychiatrist before he could properly answer that question as to the legal test, the witness said:

"I appreciate the importance of the question and I should like to make it clear why I am not prepared to answer it. Very few forms of insanity are amenable to the question which the law requires, because nowadays we do not regard insanity in terms of intellectual power or reasoning ability—medical people do not, I mean. I am here as an expert on medicine and therefore it will not be fair for me to give any opinion in words, in terms, that do not mean anything to me in this particular case. In other words, my view would be as good as anybody else's."

The question having been repeated, the witness said: "I do not think any psychiatrist could answer, or attempt to answer, that question unless he had lived with such a patient—a paranoic patient—for years."

Q. And therefore you prefer to give no answer to it? A. I give no answer.

Cross-examined by the Attorney-General

Cross-examined by the Attorney-General, the witness agreed that Haigh was a person on whose word it would be totally unsafe to rely; he denied that he had relied on it as the main basis of his opinion in this case.

Q. What objective signs of insanity are there in the prisoner? A. I think I should have to repeat all my evidence to say that

Later the witness said that there were no "objective signs of insanity"; that was one of the oldest fallacies. He relied in the main on his lifelong experience of such cases and his observation of a cumulative series of symptoms, such as verbosity, egocentricity, inability to speak the truth, absence of any shadow of remorse, stories of dreams. Paranoia was the most difficult of all mental disorders to simulate. "I may be wrong, but I do not think I would have been hoodwinked." He was not relying on any one factor. The dreams were not the main reason for his opinion, although he attached great importance to them.

Sir Hartley suggested that, although Haigh had been constantly under observation, during the time he had been in prison he had only been seen to drink his urine on one occasion, when he had publicly demonstrated that he was able to do it. The witness said that, as a result of consultations with Dr. Matheson, he was quite satisfied that it was a fact that the prisoner did have that habit, although there was no other evidence of it.

Sir Hartley: Dr. Yellowlees, you know, of course, from the prisoner's statements in this case that he is a man who, in connexion with these various murders, has practised an elaborate system of forgery and false pretences in order to possess himself of his victim's property. A. I do not know "in order to possess them"; that is not a question for me. But he has done so, I believe.

Q. Well, with the result that he possessed himself of his victim's property. A. Yes.

Q. You know that from the statements that have been read out and to which you have no doubt had access earlier. A. Yes.

Q. You have mentioned his previous convictions: you know, do you not, that those convictions were for false pretences? A. Yes.

Q. In the first case for conspiracy to defraud, aiding and abetting forgery, and uttering and obtaining money by false documents, and

obtaining money by false pretences with six similar cases taken into account? A. Yes.

Q. Do you know that on the second occasion when there were seven similar cases, the charge was attempting to obtain money by false pretences and obtaining bankers' cheques by false pretences? A. Yes.

Q. You realize that in the past he has attempted, and sometimes been successful in deceiving others? A. Yes.

Q. You think it quite impossible that he might have deceived you about these dreams? A. It depends on what subject.

Q. And the other symptoms? A. I am sorry, sir, I do not see the relation between his previous convictions to whether I believe his story about dreams.

Q. Well, you see what I am putting to you, doctor? A. Not quite.

Q. I will put it to you frankly: it is that this man has been inventing a defence and has been deceiving you in regard to these symptoms upon which you have relied for your evidence that he is a paranoic. A. Well, I would say, sir, that there is no evidence either way conclusive; my opinion is just my opinion, which I have come to in good faith and which I am bound to tell, and I do not think I am likely to be deceived on this subject, but it may well be.

Q. You may well be deceived? A. Undoubtedly.

Q. You have not relied on anything, apart from your examination of the prisoner and his statements to you, as showing that he is a paranoic? A. Yes, I think I said that I relied, or I was confirmed by the startling similarity between his behaviour and the classic account of this disease.

Witness agreed he had seen the statement by Haigh's father, and, asked if it had assisted him in coming to a conclusion, he said he could not really remember that it had; he did not think it was possible for him to explain the various grounds upon which he had come to a medical diagnosis of the case, although he would try his best to do so. He had not the least recollection of the details of the father's statement.

After some discussion as to the legal admissibility of the evidence (the terms of the statement being finally excluded), the witness was handed a copy. He did not think the father's opinion would be very valuable.

Mr. Justice Humphreys: You would not suggest that the fact that the parents belonged to the sect described as Plymouth Brethren is any evidence of hereditary insanity? A. I never spoke of hereditary insanity; I took great care not to.

Q. You talked about hereditary conditions. A. I talked about hereditary instability, and I think that the fanatically religious sects show in that very fact evidence of instability. There happens to be a classic book on the subject called *Father and Son*, by Edmund Gosse.

The Attorney-General asked if the witness had ever heard or read of a case where the drinking of blood had been an indication of insanity or a motive for murder, and the witness replied, "No, I have not."

Q. Did you ever ask the prisoner how much he had realized in pounds, shillings, and pence from the murders of the Hendersons and the McSwanns, to which he confessed? A. No, I did not regard that as my province.

Q. But were you not considering it as part of your province to discover the motives for these offences, whether it was a motive which lay in the field of insanity or a motive which belonged to a mere mercenary field? A. That, I think, was quite obvious from the first interview with him—that there was no question of motive in the popular sense at all.

In his opinion it was not a matter of importance whether or not the prisoner had gained financially from his killings.

He agreed that the prisoner elaborated the accounts of his dreams from time to time. He thought he had heard from Dr. Matheson that the prisoner had not mentioned the dreams when he had been at Lewes jail previously. He thought the prisoner could not help dramatizing everything.

Q. Did you ask whether the urge to drink blood which came to him in these dreams immediately preceded the commission of the crime or would there be a long interval in between? A. All he told me, as I gave in evidence, was that he had a dream for four or five or six nights and that during that time he would be a little abstracted or distrait at large.

Q. Would the commission of one murder satisfy the urge that these dreams created in him? A. No, it is quite incredible that it should.

Q. You mean that he might want to murder a number of people because of the same dream or series of dreams? A. Yes, or because of the same delusional system in which he might certainly want to murder a number of people.

Q. Because of the same dream? A. I do not like to use the words "because of"; that is where we differ.

Q. Because of the same urge to drink blood following the dream? A. Following upon the dream I think it is certain that he would commit further acts of violence.

The witness further said, in reply to the Attorney-General, that paranoia was a profound mental disease. The Attorney-General quoted from Professor Tanzi's book, at p. 746, that "Paranoia is not a true disease but an intellectual anomaly." The witness replied that this was simply a matter of words. Sufferers from mental diseases, if they did not recover, passed into a state of mental enfeeblement called dementia, which was shown by alterations in the brain as an organ. The exception was paranoia. A man could be a profound paranoic for fifty years and upon death the examination of his brain would reveal no changes or alterations whatever. For that reason many purists in mental medicine declined to call it a mental disease; it was not a disease of the brain in that sense.

Asked whether, in ordinary everyday language, he would call Haigh a lunatic, Dr. Yellowlees replied that among doctors he would.

Q. I quote: "Paranoia is to be regarded as a simple developmental anomaly, the product of a passionate temperament and a methodical and pedantic mind." You do not agree with that? A. I do not agree with any sentence taken out of its context and applied to somebody thirty years after the writer is dead; but in general I agree entirely with the views expressed in that chapter, and indeed it was I, as I have told you, who discovered how important it was and brought the book here.

The Attorney-General further quoted: "The paranoic is an anomalous being, but he is not a lunatic in the common sense of the term." The witness said that that was expressed in the terminology of 40 years ago; it was written in general and had no application whatever to our present conception of diseases or to this particular case.

In reply to a suggestion that by reason of mental disease a man must be presumed not to know the nature and quality of his act and that it was wrong, the witness said that, for the reasons he had already given, he had no opinion to offer on that. The word "know" was one which, as an expert, he would not use; it would not be fair. He agreed that he had given evidence in many cases of alleged insanity before, and in reply to the suggestion that he had not previously had difficulty in saying whether or not in his view a prisoner had known that what he was doing was wrong, he said he thought that was so. He did not agree that in this case the prisoner, by reason of the elaborate preparations he had made, must have known that he was doing wrong; if that had been so he would not have dreamed of coming to the court to give evidence. He agreed that the prisoner must have procured the sulphuric acid in order to destroy the body. That was presumably because he wished to avoid detection as he did not wish to be punished. The prisoner certainly knew that murder was punishable by law as a general principle.

Asked if it was his opinion that the prisoner thought he was acting in obedience to something on a higher level, the witness replied, "That is what he says, yes." He was not satisfied that the prisoner realized that the law of this country was binding upon him; he was not satisfied that he had not known it was wrong. The word "know" was very difficult.

The judge suggested the substitution of the word "believe" for "know," and the witness agreed that it would thus be easier to answer the question; he thought it was very doubtful whether the prisoner had such belief. He thought the prisoner imagined he was acting under the guidance of a higher power, but he did not know. These questions of knowledge of right and wrong had very little to do with persons in the condition in which he believed the prisoner to be; it was the most difficult of all disorders to describe satisfactorily in a legal way.

The Attorney-General: I am not asking you whether the man decided, in obedience to a higher power, to do what he realized was wrong; I am asking you to look at the facts and tell the jury whether there is any doubt that he must have known that, according to English law, he was preparing to do, and subsequently did, something which was wrong. A. I will say "Yes" if you say "punishable by law."

Q. "Punishable by law" and therefore wrong by the law of this country. A. Yes, I think he knew that

Re-examination

In re-examination the witness said he had never before given evidence in a case of pure paranoia; it was because of the difficulties arising out of pure paranoia that he was not prepared to answer the question as to whether the accused knew that what he was doing was wrong.

Sir David quoted the following passage from Professor Tanzi's book:

"Instead of believing himself to be surrounded by treacherous and hostile spirits, the paranoic with delusions of ambition is comforted by the presence of fetishes of guardian angels who, through supernatural means, are maintained in close relation with him."

That was precisely the same sort of relationship with an external force which the witness had described in his evidence.

Sir David quoted again, from p. 724:

"The paranoic delusion, on the contrary, is not a symptom, it is a mode of thought, an opinion which, however much it may be marred by preconceptions, has its roots in a special structure of the mind, in the paranoic constitution. It is the fantastic product of an egocentric but lucid spirit, which abandons itself without restraint to the mysticism of primitive man"—

a view with which the witness agreed entirely.

He agreed again that Dr. Matheson had given him every possible assistance; he had seen Dr. Matheson's own case history and had no reason whatever to doubt the facts contained therein, which in fact confirmed his own views.

The Attorney-General did not call evidence in rebuttal.

The judge, in his summing-up, outlined to the jury the principles of the M'Naghten Rules; he advised them that no jury was ever expected to decide whether or not a man was sane. That was entirely a matter for the medical authorities.

In this case the somewhat unusual course had been adopted of not calling any evidence at all as to the state of mind of the man and of asking no questions at all of any of the witnesses called for the prosecution as to whether he had exhibited any peculiarities which would make anybody think that he was not a perfectly sane and ordinary person. The defence had been content to say, "We are calling an expert upon insanity and diseases of the mind who has formed an opinion."

"Well, members of the jury," the judge continued, "if I were to say to you that you ought to follow the opinion of Dr. Yellowlees that would be, in terms, telling you to find a verdict of guilty in this case, because there is no doubt that Dr. Yellowlees, although it was very much against his will, was in the end forced to say, 'I cannot doubt that this man did know what he was doing.' He has said so in terms."

The jury retired, and subsequently brought in a verdict of "Guilty," and Haigh was sentenced to death.

Medical Notes in Parliament

Cancer and Tuberculosis Statistics

Mr. BEVAN circulated on July 14 the totals of deaths in England and Wales from cancer and tuberculosis, as follows:

Year	Deaths	
	Cancer	Tuberculosis
1920	42,420	41,439
1925	50,433	39,342
1930	56,204	34,821
1935	62,602	28,489
1940	68,922	28,144
1945	74,291	23,955
1948*	79,537	21,984

* Provisional

Grading of Hospital Staff

Mr. J. V. COLLINS on July 14 invited Mr. Bevan to define the qualifications of a senior hospital medical officer and the minimum qualifications of a consultant under the National Health Service.

Mr. BEVAN replied: "I should not presume to do so. Each individual case needs judging on its merits, by local professional committees suited to the task." He added that he had not the least intention of interfering with these committees. He could do no more than leave the matter to the members of the profession concerned. This was the first time that grading had been done, and therefore there could be no "demoting" from a superior to an inferior grade. There was a review of the initial decision, and arrangements had been made to establish machinery for the purpose.

Free Clothes for Patients

Mr. BEVAN was asked on July 14 by Mr. HAYDN DAVIES to what extent his practice was to provide free clothes for hospital patients. He replied that he had told hospitals, in effect, to go on doing what had already been proper hospital practice before the Health Service, which was to lend clothing to patients who could not provide it for themselves or get it from any other agency and to let them keep it on discharge when inquiries had made it clear that they could not otherwise get it. As in the past, this provision would normally only be required for long-stay ambulance cases without resources. Mr. Bevan deprecated the "grave misrepresentations" which certain newspapers had made in this matter.

Diphtheria Immunization

Mr. BEVAN stated on July 14 that doctors who certified deaths as due to diphtheria were not under an obligation to state whether the victims had been immunized. He explained that since diphtheria was a notifiable disease medical officers of health knew of fatal cases and could usually tell from the local authority's immunization records whether a child who died from diphtheria had been immunized.

Claim to Cure Mastitis

Sir WILLIAM Y. DARLING on July 12 asked the Secretary of State for Scotland why a registered medical practitioner who claimed to have a cure for mastitis and had made offers to his Department was not allowed to demonstrate this cure without submitting in advance information which might prejudice a fair examination of the claim.

Mr. WOODBURN replied that the medical practitioner referred to was free to demonstrate his alleged cure for mastitis, but it could not receive official backing until it had been thoroughly tested by impartial scientific experts. For that purpose details and method of treatment required to be disclosed. He could not accept the suggestion that disclosure of that information in advance might prejudice a fair examination of the claim.

Compound E

On July 12 Mr. A. R. BLACKBURN asked, in view of the evidence as to the efficacy of compound E in the treatment of rheumatic diseases, what steps were being taken through the Medical Research Council or other bodies to ensure the production of this drug on a large scale at the earliest possible date.

Mr. HERBERT MORRISON answered that research aimed at finding effective new substances akin to compound E was in active progress under the Medical Research Council. All these compounds were exceptionally difficult to make, and early success was not to be expected. Large-scale production of compound E itself was a matter for commercial laboratories rather than the Council, but again the difficulty of synthesis must hamper speed. American manufacturers of the compound had intimated that it was unlikely to be generally available for use by doctors even in the United States for several years at least.

Pulheems

Mr. D. RENTON asked on July 12 which medical categories qualified soldiers for service at Hong Kong.

Mr. E. SHINWELL said the fitness of soldiers for service overseas was assessed under the Pulheems system of medical classification, which had replaced the former medical categories.

Universities and Colleges

UNIVERSITY OF ST. ANDREWS

J. M. S. Manson received the degree of M.D. (with commendation) at the Graduation Ceremony held on June 30.

UNIVERSITY OF LONDON

The title of Professor Emeritus of Anatomy in the University has been conferred on Professor John Kirk, M.B., Ch.B., F.R.C.S.Ed., on his retirement from the S. A. Courtauld Chair of Anatomy at Middlesex Hospital Medical School which he has held since 1937.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on July 14, Sir Cecil Wakeley was elected President in succession to Lord Webb-Johnson. Sir Harry Platt and Professor Ernest Finch were elected Vice-presidents.

Mr. Digby Chamberlain, Sir Stanford Cade, and Mr. A. Dickson Wright were admitted as Members of the Council.

Professor D. E. Derry, of Cairo, was admitted to the Fellowship, having been elected as a medical practitioner of 20 years' standing.

Professors and Lecturers for the ensuing year were appointed as follows:

Sir Henry Wade was appointed Thomas Vicary Lecturer.

Lord Webb-Johnson was re-elected as the representative of the College on the governing body of the British Postgraduate Medical Federation.

Diplomas of Fellowship were granted to *Manibhai Ashabhai Patel* and to Himadri Kumar Sarkar.

Dr. T. J. Gilmartin, Dr. Alan Cogswell, Dr. T. T. P. Murphy, and Dr. W. D. Arnison were elected Fellows of the Faculty of Anaesthetists.

Diplomas in Psychological Medicine and in Laryngology and Otology were granted jointly with the Royal College of Physicians of London to the following successful candidates:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—Y. I. Al-Kadi, G. H. L. Bullmore, R. L. Buttle, T. Elmahi, M. Engler, M. B. Feldman, W. N. L. Haynes, S. K. Jetley, D. H. Jones, D. T. Maclay, J. C. Marfatia, J. R. Mathers, D. L. Murti Rao, C. M. Vaillant, W. S. Watson.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.—B. S. Alderson, S. W. Allinson, N. C. Banerjee, H. A. Beagley, R. D. Bell, D. L. Chadwick, S. L. Citron, G. A. Dalton, W. V. Doyle-Kelly, C. N. d'E. Eastes, L. Fisch, T. B. Gupta, E. W. R. Hackett, J. T. M. C. Jenkins, T. Manickam, A. Mares, S. R. Mawson, M. J. Maxwell, M. F. A. O'Connor, M. L. O'Mara, J. T. Rossouw, C. C. D. Shute, Noreen M. Simpson, J. N. S. Taylor, J. D. Thompson.

The following hospitals were recognized under paragraph 23 of the *F.R.C.S.* regulations: Fulham Hospital (junior surgical registrar, first and second house-surgeons); Wanstead Hospital (Resident surgical officer and house-surgeon); Royal Salop Infirmary, Shrewsbury (second house-surgeon at Copthorne Hospital).

Hunterian Professors.—Mr. R. I. Harris, one lecture on spondylolisthesis; Mr. C. F. M. Saint, one lecture on stomatodaeal ruminations, clinical and non-clinical; Dr. S. A. Henry, one lecture on cutaneous cancer in relation to occupation; Mr. D. J. Browne, one lecture on congenital deformities of the urethra, vagina, and anus; Mr. J. B. Oldham, one lecture on renal denervation; Mr. J. E. Piercy, one lecture on factors contributing to safety in surgery of the thyroid; Mr. J. E. A. O'Connell, one lecture on a review of 500 surgically treated cases of lumbar intervertebral disk protrusion, with special reference to the late results of operation; Mr. H. F. Moseley, one lecture on ruptures of the rotator cuff; Mr. H. L. M. Roualle, one lecture on malignant disease of thyroid gland; Mr. E. M. Evans, one lecture on fractures of the radius and ulna; Dr. Ruth E. M. Bowden, one lecture on factors influencing functional recovery of peripheral nerve injuries; Mr. R. S. Murley, one lecture on post-operative venous thrombosis and embolism; Mr. M. R. Ewing, one lecture on villous tumours of the rectum; Mr. E. M. Nanson, one lecture on the respiratory responses to operative trauma.

Arris and Gale Lecturers.—Mr. D. F. E. Nash, one lecture on surgical aspects of renal damage in childhood: assessment, salvage, and aftermath; Dr. F. D. Stephens, one lecture on the diagnosis and management of Hirschsprung's disease; Mr. E. S. R. Hughes, one lecture on the development of the mammary gland.

Erasmus Wilson Demonstrators.—Mr. C. E. Shattock, two demonstrations; Mr. P. H. Mitchiner, two demonstrations; Mr. L. W. Proger, two demonstrations.

Arnott Demonstrators.—Mr. R. J. Last, three demonstrations; Dr. F. S. Gorrill, three demonstrations.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ending July 9. [No. 27

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each Infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949 (a)	(b)	(c)	(d)	(e)	1948 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Stillbirths	185	26	34			205	29	23		
Rate per 1,000 total births (including stillborn)			33					21		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

The number of notifications in the week ended July 16 was: poliomyelitis 112 (73), polio-encephalitis 5 (4). (Figures for the previous week are in parentheses.) Thus the rise in incidence, which was temporarily arrested last week, has set in again. Cases were widely distributed, but except for two in the Wigton R.D. in Cumberland there were none north of the West Riding. Only one case was reported in the eastern counties.

Multiple cases (poliomyelitis and polio-encephalitis together) were reported from the following counties: London 13 (6), Berkshire 2 (0), Cheshire 3 (2), Cornwall 4 (5), Cumberland 2 (0), Devon 9 (11), Essex 3 (1), Gloucester 6 (3), Hertford 2 (4), Lancaster 7 (5), Leicester 2 (1), Middlesex 11 (5), Southampton 14 (2), Surrey 4 (1), Sussex 2 (1), Warwick 2 (3), Yorks West Riding 19 (10), Glamorgan 4 (3).

The rise so far this year is closely commensurate with the upward trend which occurred during July two years ago. In the corresponding week of 1947 an "unprecedented prevalence" was forecast. Although once again an unusually high incidence is to be expected, there is a definite possibility that the curve of notifications will flatten out. Up to the present the large centres of population are not seriously involved.

Poliomyelitis Film

A 60-minute film entitled "Polio: Diagnosis and Management," produced by the Crown Film Unit in 1948 for the Ministry of Health, is now available. It is suitable for general-practitioner audiences and could be seen with advantage by nurses, physiotherapists, and public health staffs. The film is obtainable in 35- and 16-mm. sizes on loan from the Central Film Library, Imperial Institute, South Kensington, for showing to professional audiences if the organizer has his own projector; otherwise it can be shown on the C.O.I. mobile film units, by application to the regional film officer of the C.O.I., to professional audiences who can provide a properly blacked-out hall.

Prevalence and Tonsillectomy

In the memorandum on poliomyelitis by medical officers of the Ministry of Health (*British Medical Journal*, July 26, 1947) the following statement was made: "There is, however, overwhelming evidence that a recent tonsillectomy increases the risk of a child contracting poliomyelitis, particularly of the bulbar type. Prevalence of poliomyelitis in an area should therefore be an indication for the postponement of operations on the nose and throat whenever possible." The subject was discussed at the B.M.A. meeting in 1948 (*British Medical Journal*, July 17, 1948, p. 151) and the evidence was summarized by Glover (*Monthly Bulletin of the Ministry of Health*, 1948, 7, 150).

Clearly the decision whether a particular child should be operated on at a particular time and place is one for the surgeon performing the operation. This decision depends on balancing the probable benefit to the child against the probable risks of the operation. Both the benefits which may follow the operation and the danger of the child's developing bulbar poliomyelitis are to a great extent imponderable.

It has been established by many studies in the U.S.A. that when multiple paralytic cases are occurring in an area virus is widespread and the carrier rate is high, but there is no practicable routine way of detecting healthy carriers of virus. The medical officer of health of the area in which a child lives has up-to-date information on the incidence of poliomyelitis in his area, and the surgeon should take the local prevalence of poliomyelitis into account when considering the desirability of operating. Information on the incidence will continue to be reported in these columns.

Poliomyelitis in New York

Dr. Harry S. Mustard, Health Commissioner of New York City, has announced that the number of cases of acute poliomyelitis reported to the Health Department since the beginning of the year is well above the average for the last 20 years, but it is still too early to determine whether this will be a bad year (*New York Times*, July 15). In the first fortnight of July, 64 cases were reported. There were 12 cases in June, 3 in May, 1 in March, and 1 in January.

Discussion of Table

In *England and Wales* a decrease occurred in the number of notifications of measles 1,413, scarlet fever 85, whooping-cough 77, acute pneumonia 30; while increases were reported for diphtheria 23, paratyphoid fever 19, cerebrospinal fever 16, and dysentery 10.

The largest decreases in the notifications of measles were London 191, Warwickshire 158, Gloucestershire 99, and Surrey 88. The only large variation in the local trends of scarlet fever was a decrease of 30 in London notifications. Fluctuations occurred in the local returns of whooping-cough; the largest were decreases in Lancashire 66 and Surrey 31, and a rise of 52 in Durham. There was an increase in the notifications of diphtheria in London from 14 to 27 (Bermondsey 17), and an increase also of 12 cases in Liverpool C.B.

The only large return for paratyphoid fever was Lancashire 20 (Liverpool C.B. 16). The chief centres of dysentery were Lancashire with 23 notifications (Liverpool C.B. 18) and London with 10.

Nine cases of acute encephalitis lethargica were notified during the week, the largest return during recent years. Six of the 9 cases were notified in Cambridgeshire (Chesterton R.D.).

The greatest numbers of notifications of food-poisoning were in Yorkshire West Riding (Settle R.D.) 332 and the City of London 44.

The notifications of acute poliomyelitis were 7 fewer than in the preceding week. The largest returns were those of Devonshire 10 (Okehampton R.D. 5, Exeter C.B. 2, Northam U.D. 2); Yorkshire West Riding 10 (Dewsbury C.B. 2, Leeds C.B. 2, Batley M.B. 2, Colne Valley U.D. 2); London 5 (Wandsworth 2); Middlesex 5 (Hornsey M.B. 2); Cornwall (Camborne-Redruth U.D.) 5; Hertfordshire 4 (Hatfield R.D. 2); Lancashire 4 (Liverpool C.B. 2, Darwen M.B. 2); Glamorganshire 3; Gloucestershire 3 (Bristol C.B. 2); Nottinghamshire 3 (Basford R.D. 2).

In *Scotland* infectious diseases were less prevalent, and the fall in the number of notifications included measles 58, acute primary pneumonia 39, dysentery 34, whooping-cough 18, scarlet fever 16, diphtheria 11.

In *Eire* decreases were recorded in the number of notifications of measles 48, whooping-cough 16, primary pneumonia 15. The largest decreases in measles were Dublin C.B. 34 and Kerry (Listowel R.D.) 28. An outbreak of 10 cases of scarlet fever was notified in Tipperary (Tipperary U.D.).

In *Northern Ireland* decreases were reported in the number of notifications of measles 20 and diphtheria 8. The fall in measles was contributed by counties Antrim and Armagh.

Week Ending July 16

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,043, whooping-cough 2,184, diphtheria 104, measles 5,376, acute pneumonia 330, cerebrospinal fever 17, acute poliomyelitis 112, dysentery 68, paratyphoid fever 50, typhoid fever 6.

Osler Centenary Celebrations at Oxford

To mark the centenary of the birth of Sir William Osler the Oxford Division of the British Medical Association arranged a medical meeting and a dinner on July 12. It was appropriate both that the principal celebration took place in Oxford and that it was sponsored by the Association, for it was at the annual meeting at Oxford in 1904 that Osler decided to accept the regius chair at Oxford. The medical meeting was held at the Sir William Dunn School of Pathology, where Lieutenant-General Sir William MacArthur spoke to a large gathering on: "Of the Smallpox: a Review in the Osler Tradition." Sir William was followed by Professor Sir Henry Cohen, whose talk on "Subacute Bacterial Endocarditis" included an account of the part which Osler had played in the recognition of the condition. The commemorative dinner, at which over 200 were present,

was held at Christ Church, the principal speakers being Professor J. A. Ryle, Sir Hugh Cairns, and Professor A. D. Gardner. Dr. Peyton Rous, of the Rockefeller Institute, replied on behalf of a large number of distinguished guests. Great credit is due to the organizing committee and its secretary, Dr. C. W. M. Whitty, for the excellent arrangements made for the occasion.

Osler Club's Visit to Oxford

On Saturday, July 16, as part of the centenary celebrations, members of the Osler Club made a pilgrimage to places in Oxford associated with their "patron saint." After a visit to the collection of Robert Burton's books reassembled by Osler, the party lunched in hall at Christ Church with Professor A. D. Gardner, the Regius Professor of Medicine. In the early afternoon, through the courtesy of the librarian of the Radcliffe Science Library, the very interesting exhibition, arranged with the assistance of Dr. A. H. T. Robb-Smith and Dr. H. M. Sinclair, was inspected, and afterwards the party visited Osler's room in the Radcliffe Museum. Following a tour of 13, Norham Gardens, the warden, Miss Fairburn, provided tea in the drawing-room which Osler had added to the house. The day was concluded by breaking the return journey at Ewelme and visiting the charming old almshouse of which Sir William Osler was, in common with regius professors since Stuart times, *ex-officio* master, but in which he was the first to take a great interest. The beautiful little St. Mary's Church, which adjoins the almshouse and contains the memorial tablet to Osler and his family, is suffering from the ravages of the death-watch beetle; it would be appropriate in this centenary year if admirers of Osler expressed their respect for him by sending to the vicar of St. Mary's a contribution towards the cost of restoration.

Royal Institute of Public Health and Hygiene

The Harben Medal was presented to Lord Boyd-Orr, F.R.S., and the Smith Award to Dr. M. T. Morgan at a meeting of the Royal Institute of Public Health and Hygiene on July 21.

Industrial Health Services Inquiry

The committee set up by the Prime Minister, under the chairmanship of Judge E. T. Dale, to examine the relationship between the National Health Service and the industrial health services which make a call on medical man-power (June 11, p. 1056) met in London on July 22. Various bodies will be invited to give evidence.

Studying Medical Education

Dr. Anistas Shahine, dean of the faculty of medicine in the Syrian University, Damascus, is visiting Britain under the auspices of the British Council. After attending the Fourth International Congress of Otolaryngology held in London on July 18–22, he is studying the British system of medical education. Dr. Shahine qualified from the Syrian University in 1924 and later studied in Paris, specializing in diseases of the ear, nose, and throat. He joined that department of the Syrian University and was appointed professor in 1943, becoming dean of the faculty of medicine this year.

Hospitals Contributory Schemes

The British Hospitals Contributory Schemes Association (1948) held a general meeting on July 15, and accepted in principle a draft constitution prepared by its provisional executive committee. Mr. Henry Lesser was elected president, Mr. W. G. Nevin honorary treasurer, and Mr. John Dodd honorary secretary. During the year ending June 30, 1949, twenty-five contributory schemes had collected £1,738,340. The members of the scheme and their dependants are entitled to various benefits supplementary to those of the National Health Service. Figures are not available for at least twelve other schemes. Ten schemes collected £193,642 for charitable purposes such as hospital amenity funds, medical research, and medical charities. The association operates a clearing house, by agreement with the Treasury, for the receipt and distribution among the various schemes of contributions deducted from Civil Service salaries. The clearing house is handling about £30,000 a year.

Health Service Expounded

A pamphlet entitled *The National Health Service* has been prepared by the Ministry of Health and the Central Office of Information (H.M.S.O., price 6d.) describing the purpose of the National Health Service and how it is administered. It is intended for anyone at home or abroad interested in the Service, "and for those who are workers in the Service, without whose understanding and whole-hearted effort it could not succeed." It gives a fairly objective account of the general-practitioner and hospital services available, and, though enthusiastic about the effects of the Service, does not shirk mentioning the deficiencies that exist at present. Readers are warned in parenthesis that a private patient "must also pay to have his prescription made up at the chemist's—because the medicine cannot be regarded as separable from the doctor's advice and treatment." It admits that "the public has still to learn how to use the new facilities properly and economically," and adds: "Those who are actually running the Service have to get used to new conditions and changing needs."

WHO Sanitation Measures

A project costing $1,000,000 to improve sanitation throughout the world has been adopted by the Programmes Committee of WHO. Fifteen teams will give demonstrations on housing, town planning, and rural hygiene. The committee has also approved sanitary regulations to replace the various sanitary conventions adopted between 1903 and 1944. The guiding principle is the active suppression of epidemic disease wherever it appears.

Health Centres in London

The Health Committee of the London County Council is proposing that the Council shall acquire a site of about two acres at Southend Lane, Lewisham, for the purpose of a health centre. This will serve an extensive health service area and include two neighbourhood units which will contain ultimately a population of about 14,000 to 15,000, including the inhabitants of the Council's Bellingham and Flower House estates. The building will probably not be started for another five or seven years. It is also proposed to proceed forthwith to acquire certain sites in Walmer Road and Threshers Place, Kensington, for the erection of a comprehensive health centre. Both at Lewisham and Kensington it will probably be necessary to exercise powers of compulsory purchase, and permission under the Town and Country Planning (Development by Local Planning Authorities) Regulations, 1948, will be required.

Heberden Society

The Heberden Society held its annual meeting at Oxford on July 15 and 16, when the Heberden Round was taken at the Radcliffe Infirmary by Dr. Sidney Truelove in the absence of Professor L. J. Witts. Seven cases were presented for discussion by Dr. Truelove and members of Professor Witts's unit. They included a case of sclerodactyly and oesophageal stricture, on whom oesophagectomy had been performed. The pathology was discussed by Dr. Robb-Smith with the aid of slides. Other cases presented were: rheumatoid arthritis with Sjögren's syndrome; neuritis of the deep branch of the ulnar nerve, occupational in origin; ankylosing spondylitis with involvement of the peripheral joints resembling rheumatoid arthritis; hypertrophic pulmonary osteo-arthropathy, which was suggested to be pachyderma and pachyperiostitis; idiopathic steatorrhoea, which presented as anaemia and subsequently developed osteomalacia; and chronic hepatitis of nine years' duration with gross oedema and ascites and a subsequent remission following omentopexy four years ago. Dr. W. S. C. Copeman was in the chair, and Professor A. D. Gardner, regius professor of medicine, welcomed members of the society. On the previous evening a dinner was held in Magdalen College, with Dr. E. M. Buzzard acting as host to the members.

COMING EVENTS

Edinburgh Lectures

A series of open lectures has been arranged by the Edinburgh Postgraduate Board for Medicine in connexion with the post-graduate course in the medical sciences which commenced on July 4. The lectures, which are being delivered in the anatomy lecture theatre of Edinburgh University, began on July 11, when Sir James R. Learmonth discussed thrombosis; on July 18 Professor G. W. Pickering, the physiology of hypertension; and on July 28 Sir Lionel Whitby, the present position regarding leukaemia. Details of the remaining lectures will be published in the diary column of the *Journal* week by week. All students and graduates are invited to attend.

Congress of Military Medicine

The 12th International Congress of Military Medicine and Pharmacy will be held in Mexico on Oct. 23–29. It will be followed by a conference of the International Office of Military Medicine Documentation on Nov. 6–8 at Havana, Cuba. Information may be obtained from the General Secretary of the Comité International de Médecine et de Pharmacie Militaires, 79, Rue Saint-Laurent, Liége, Belgium.

SOCIETIES AND LECTURES

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, Aug. 2, 4.30 p.m., "*The Principle of Venous Pressure Reduction in the Treatment of Heart Failure*," by Professor J. McMichael.

APPOINTMENTS

Mr. D. Roy McCullagh, Ph.D., has been appointed director of the Sterling-Winthrop Institute's biochemistry laboratories, New York.

Mr. McCullagh has recently been carrying out research in endocrinology. He graduated with the degree of B.Sc. at the University of Manitoba, Canada, and in 1929 obtained the degree of Ph.D. at Cambridge University, where he studied under Sir Frederick Gowland Hopkins, Dr. T. S. Hele, and Professor J. B. S. Haldane.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Seward.—On July 10, 1949, to Margaret Mary (née Vaughan), wife of F. W. R. Seward, M.R.C.S., L.R.C.P., a daughter—Suzanne Margaret Linda.

Sherry.—On July 10, 1949, to Kathleen Robinson, F.R.C.S., wife of Dr. Vincent F. Sherry, a daughter.

MARRIAGES

Westlake—Whitton.—On June 29, 1949, at Alyth, Perthshire, Ernest Keith Westlake, M.B., B.Chir., to Nora Whitton.

DEATHS

Bell.—On July 21, 1949, Douglas Bell, M.B., D.P.H., of Cliffe House, Skelmanthorpe, Huddersfield, Yorks, aged 66.

Crossley.—On July 20, 1949, Leonard Crossley, M.D., of Highfield, Winsley, Bradford-on-Avon, Wilts.

Dalrymple.—On July 17, 1949, at 13, Southfield Road, Bude, Cornwall, Joseph Dalrymple, C.M.G., O.B.E., L.R.C.P.&S.Ed., L.R.F.P.S.Glas., Colonel R.A.M.C., retired, aged 80.

Davies.—On July 19, 1949, at Southsea, John Phillip Henry Davies, M.B., B.Ch., D.P.H., of Elgin, Llanishen, Cardiff.

Fletcher-Jones.—On July 11, 1949, at Chester, Arthur Fletcher-Jones, L.R.C.P.&S.Ed., L.R.F.P.S.Glas., aged 75.

Jackson.—On July 11, 1949, in hospital, Violet Jackson (née Conway), M.B., Ch.B., D.R.C.O.G., of 408, Street Lane, Leeds, 7.

Jones.—On July 11, 1949, at Beaconsfield, Bucks, Lawrence Jones, M.S., F.R.C.S.

Kelly.—On July 19, 1949, at Strathview, Friar's Lane, Lanark, Joseph Owen Kelly, F.R.C.S.Ed.

MacGregor.—On July 18, 1949, at Craigmount, Peebles, Scotland, Angus Vallance MacGregor, M.D., late of West Hartlepool, aged 82.

Marsden.—On July 10, 1949, at 25, Rathen Road, Withington, Manchester, 20, Richard Walter Marsden, M.D., B.Sc., F.R.C.P., D.P.H., aged 81.

Rait-Smith.—On July 14, 1949, at Hill End Hospital, St. Albans, Herts, Brian Rait-Smith, M.R.C.S., L.R.C.P., D.A., F.F.A.

Robertson.—On July 21, 1949, at Farbills, Fort Augustus, John Joseph Robertson, M.B., Ch.B., of 38, Highburgh Road, Glasgow, W.

Shackel.—On July 14, 1949, George Arthur Shackel, M.R.C.S., L.R.C.P., of Erleigh, Mayfield, Sussex, aged 87.

Stewart.—On July 16, 1949, at Burst Garth, 2, Dallam Road, Shipley, Yorks, William Craig Stewart, M.B., Ch.B., F.R.C.S.Ed.

Sutter.—On July 9, 1949, at 44, Burges Road, Thorpe Bay, Essex, Robert Ross Sutter, M.D., late of Warboys, Hunts.

Walton.—Recently, Donald Walton, L.M.S.S.A., of Astule House, Oxford Road, Macclesfield, Cheshire.

Wilson.—On July 18, 1949, at Normanton, Charles Haddon Wilson, M.B., Ch.B.

Woodman.—On July 20, 1949 at 272, Battle Road, Hollington, St. Leonards-on-Sea, William Edwin Woodman, M.D., aged 94.

Wight.—On June 22, 1949, at 7, Dundas Avenue, Dudley, Worcs, George Douglas Wight, M.B., Ch.B., D.P.H.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Green Staining of Teeth

Q.—*What is the cause of green staining of the teeth? Can this affect the permanent as well as the deciduous teeth, and is any treatment possible?*

A.—The most common form of green stain affecting teeth is of extrinsic type on the outside of the teeth and it can be removed. It is usually seen on the gingival third of the facial surface of the maxillary anterior teeth in children. The causation is not certain, but it is thought to be due to the action of chromogenic bacteria and is as a rule associated with poor oral hygiene. Intrinsic staining is far more rare, and is usually due to bile pigments carried to the pulp, from which they probably enter the dentinal tubules. Copper amalgam, which is occasionally used for filling deciduous teeth, will sometimes give rise to a greenish stain which permeates the teeth. Staining of the deciduous teeth appears to be more common than that of permanent teeth, although involvement of the latter has been recorded, and John Hunter (*Works*, ed. J. F. Pamer, 1835, 2, 19) refers to the effect of jaundice on adult teeth. The treatment of the extrinsic type is simple and consists in scaling and polishing.

Intrinsic staining, if of the deciduous teeth, can be left. If, however, it is present in the permanent dentition, a difficult problem arises, since the introduction of bleaching agents necessitates entry into the pulp canal, the teeth thereby being devitalized. This procedure threatens the life of the teeth and gives rise to the risk of subsequent apical abscesses, etc. Severe staining of the anterior teeth is probably best dealt with by cutting down the tooth to a peg, leaving the pulp alive, and cementing a porcelain or acrylic resin crown over the peg. Reports of cases of green staining of the teeth have been made by the following: Craig, *British Medical Journal*, 1925, 1, 453; Ellis, *Proc. roy. Soc. Med.*, 1938, 31, 767; Boyle and Dinnerman, *Amer. J. Orthodont.*, 1941, 27, 377; Thursfield, *Proc. roy. Soc. Med.*, 1912, 5, Sect. Clin. Med., 148; and Langmead, ibid., 147.

Treatment by Tridione

Q.—*May I have some information about the use of tridione in petit mal and pyknolepsy? (1) How long should a patient be kept in hospital at the beginning of treatment? (2) How often are leucocyte counts necessary? (3) What are the toxic effects, and at what period of the treatment are they likely to arise? (4) Has treatment to be continued indefinitely?*

A.—(1) There is no need in the ordinary way to have a patient in hospital when starting treatment with tridione. (2) White blood-cell counts may be done once a fortnight for the first two months and then once a month, the frequency being reduced as time goes on. Attention should be paid to the actual number of polymorphonuclear leucocytes, and any counts below 4,000 per c.mm. should call for care. (3) Possible toxic effects, which are generally not so bad as the literature might suggest, include agranulocytosis, aplastic anaemia, and episodic hiccup; apart from the changes in the blood, these occur very early. (4) Treatment usually has to be continued indefinitely.

Hypertensive Blood Donors

Q.—*I understand that blood from patients suffering from hyperpiesis is not always suitable for transfusion purposes. Is this correct, and, if so, why? I should also like to know whether it is dangerous to bleed these patients?*

A.—There is no risk to the recipient when blood from a hypertensive subject is transfused. There is little risk to a benign hypertensive donor in relatively good health; but when degenerative vascular changes have set in there is some danger

of a stroke should the blood-letting result in syncope. Patients with angina run a similar risk of cardiac infarction in the event of syncope.

Threatened Abortion

Q.—*A young primigravida three months pregnant has had a moderate blood loss lasting four days, but the haemorrhage has now stopped. What are the chances that the foetus is alive, and how long can it be left with safety if it is not?*

A.—S. Bender found that in about 10% of all cases diagnosed clinically as of threatened abortion the foetus was dead at the time of investigation (*British Medical Journal*, 1948, 1, 683). In the case in question, however, if there has not been any recurrence of bleeding or any discharge since the original haemorrhage, there is considerably more than a 90% chance that the foetus is still alive. There is no reliable method of making an immediate diagnosis, but estimation of the urinary pregnanediol or a biological pregnancy test, if carried out now and repeated again in a few weeks, might help. There is no harm in adopting a "wait and see" policy; indeed, that is the only way to make sure of the diagnosis. Provided there is no intervention, there is practically no risk to the patient even if the products of a missed abortion are retained for many months. Occasionally, however, minor upsets, such as general malaise and skin rashes, presumably due to absorption of products of degeneration, are seen.

Post-herpetic Pain

Q.—*A man aged 66 had a severe attack of herpes zoster of the right frontal region 15 months ago. The whole frontal region remains hypersensitive to touch, heat, and cold, while a severe neuralgia similar to the pain of the acute herpes still occurs. The patient is also blind in the eye opposite to the herpes, following corneal ulceration, and he has limited vision in the other eye. What further treatment is advised, apart from the continued use of analgesic drugs? Would nerve injection with alcohol interfere with the remaining vision?*

A.—It appears that the eye on the same side as the herpes has already suffered damage. Since nerve injection sometimes causes keratitis in a normal eye, the use of this method of producing analgesia might have grave consequences. The relief of pain in such cases is always a difficult problem and one not always capable of solution. The pain may persist for many years. Deep *x*-ray therapy has been tried with some success, but the mainstay of treatment is the use of analgesic drops.

Ulcerative Colitis

Q.—*A woman aged 35 has suffered periodically for three years from attacks of vomiting and blood-stained diarrhoea. Bacteriological examination is repeatedly negative, and the diagnosis is apparently non-specific ulcerative colitis. Recently the condition responded rapidly to phthalylsulphathiazole, but on stopping the drug there seems to be a tendency to relapse. (1) How long will it be safe to continue with this drug? (2) Could the intestinal flora be kept more nearly normal by giving, say, lactose after stopping phthalylsulphathiazole? (3) Is penicillin likely to be of use? (4) If the case proves resistant, would retention enemata be of any avail?*

A.—It is not uncommon to find that phthalylsulphathiazole controls the diarrhoea of ulcerative colitis, and at times a course of treatment may initiate a remission. Unhappily, relapse immediately the drug is withdrawn is frequent. When this treatment was originally introduced a dosage of 0.2 g. per kilo of body weight four-hourly for four weeks was recommended. The part played by the bacterial flora of the bowel is uncertain; there is no evidence that ulcerative colitis is primarily a microbic infection, and thus no reason to suppose that a change in the bowel organisms would benefit the patient. At one time an emulsion of *Lactobacillus acidophilus* was often prescribed with the aim of altering the bacterial flora, but it had no noticeable effect on the course of the disease. Penicillin may control secondary bacterial invasion of the ulcerated colon; the importance of this process is hard to assess, and the effects of the drug are not impressive. Retention enemata of 7 to 10 g. of phthalylsulphathiazole in 200 ml. of water or mucilage have been employed and are often useful.

NOTES AND COMMENTS

Unilateral Flush after Food.—Dr. THEODORE JAMES (Boston, Mass.) writes: In 1945, under this heading, you published a question I put to you (*British Medical Journal*, 1945, 1, 687). This drew two interesting comments from Dr. F. Parkes Weber (p. 758) and Dr. A. D. McDwyer (p. 794). It might be of interest, therefore, to record, because of the rarity of the phenomenon, two more almost identical cases which came within the ambit of my experience within less than three months last year. The first was a boy of 10 who was seen with the chief complaint of poliomyelitis. The story of unilateral flushing of the face after food was volunteered by his mother during the taking of the history. This had first been noticed in very early childhood, was becoming less frequent, and more often than not required spices to provoke it. The boy himself could guarantee dill pickle to produce it when other agents failed. Sweating was not in evidence. The second case was a little girl of 2 who was presented by her mother for repair of her cleft palate, and as an afterthought requested that something be done about a unilateral flushing of the face which recurred regularly with or after meals, and had been doing so for some time. In neither of these two cases were there any associated subjective symptoms, and in all three the manifestation was on the left side of the face. Not even suggestive evidence of previous local pathology was forthcoming.

Dicoumarol and Prothrombin Level.—Drs. ROSEMARY BIGGS and R. G. MACFARLANE write from the Pathological Department of the Radcliffe Infirmary (Oxford): Under "Any Questions?" (July 2, p. 38) you print a reply to a correspondent who is interested in the control of dicoumarol therapy. In this, Russell viper venom is recommended as thromboplastin for the estimation of prothrombin by the one-stage technique. We feel that the particular correspondent, and any others who may read this reply, should know that the use of the venom, with or without lecithin as a substitute for brain, may give most misleading results. Higher values for the "percentage of prothrombin" may be obtained with venom than when brain is used as thromboplastin. Lempert[1] has drawn attention to this danger in your columns, and we have since then been informed of several cases in which disastrous overdosage of dicoumarin was encouraged by an apparently safe level of prothrombin as estimated with venom. These and other experiences have prompted investigation of the difference between Russell viper venom and brain (Wilson,[2] Biggs and Macfarlane,[3] Mawson[4]). These investigations have all shown the danger of this modification of Quick's one-stage technique. We feel that venom, with or without lecithin, should not be used for any routine estimation of prothrombin and that it is particularly undesirable when used for the control of such a dangerous drug as dicoumarol.

Drs. K. P. BALL and H. O. HUGHES, writing from the Central Middlesex Hospital (London, N.W.), also refer to the work quoted above by Drs. Biggs and Macfarlane. They continue: We too have found that Russell viper venom is a most insensitive thromboplastin in the estimation of dicoumarol hypoprothrombinaemia using Witts and Hobson's technique. Serious haemorrhages are liable to occur with little increase in the prothrombin time. Since changing to Quick's method, using brain extract as thromboplastin, significant spontaneous haemorrhages have fallen from 10.4% to 1.5%. No serious haemorrhage has occurred when the plasma prothrombin content exceeded 10%. The use of Russell viper venom inevitably leads sooner or later to serious dicoumarol haemorrhages, and as a result a valuable drug is blamed.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JULY 30 1949

THE SECRETARY REPORTS

GENERAL MEDICAL SERVICES

Discussions between the General Medical Services Committee and the Ministry of Health, which go steadily on, have yielded in recent months a number of useful concessions. For example, a practitioner in attendance on a pregnant woman is now entitled, in the eleventh week before the expected date of confinement, to give a single certificate to cover the rest of the pregnancy and the puerperium. An ordinary weekly certificate will be required for cash benefit purposes prior to the beginning of the eleven-weeks period, but the new certificate will ease the burden of certification for the greater part of the last three months of pregnancy.

Again, there is to be an improvement in the lay-out of the prescription form and in the binding of these forms. Under the heading "Specially Expensive Drugs" ethisterone is to be added to the list of drugs for which a dispensing doctor may receive additional payment if he supplies it.

Another point of interest to the general practitioner is the decision to allow a six-months period of grace after the return of a communication through the dead-letter office before a person's name is removed from the doctor's list. The effect is to give a six-months "reprieve" during which inquiries may be completed as to the person's whereabouts and the necessity or otherwise of removing his name from the medical list.

Terms of Service for Hospital Staffs

The announcement by the Joint Committee published in these columns last week contained a statement the significance of which some may have missed. It was to the effect that the Ministry had agreed that, wherever a patient entered a private ward, that patient would become liable for the payment of professional fees to part-time practitioners, in addition to the maintenance charges, except where the patient is occupying accommodation under the proviso to Section 5 (1) of the Act—i.e., where a public patient is admitted or transferred to private accommodation for clinical reasons. This should bring to an end the procedure which is being followed in some hospitals. For example, in some cases the hospital authorities have gone to some pains to remind the patient entering a private ward that he could have gone into a public ward free of cost under the Service. A typical form is as follows:

I have read the conditions of admission to pay-bed accommodation at the above hospital as set out overleaf and agree to pay the appropriate charges as stated below.

SECTION 4 Accommodation	.. ..	Not yet available
SECTION 5 (1)	(*a*) Single Ward	£1 9s. 0d. per day
	(*b*) 2 Bedded Ward	£1 6s. 7d. per day
	(*c*) 3 or more Beds	£1 4s. 2d. per day
SECTION 5 (2)	(*a*) Single Ward	£1 4s. 3d. per day
	(*b*) 2 Bedded Ward	£1 2s. 3d. per day
	(*c*) 3 or more Beds	£1 0s. 3d. per day

In this category, you will be responsible for paying the doctor's fee up to a maximum of 75 guineas.

I wish to occupy a pay-bed under section.....at a cost of .....per day.

Signature.....
Date.....
Witness.....

Note.—Under the National Health Service Act, 1946, the Minister of Health allows certain accommodation in hospitals to be set aside as pay-bed accommodation. The regulations provide:

1. *Section* 4.—Accommodation where patients pay an *inclusive* daily charge of a few shillings for the privilege of occupying a single or small private ward of two or more beds.

2. *Section* 5 (1).—The patient pays the full maintenance charge plus an amount to cover the services of the visiting medical staff. No private arrangements with the doctor are made under this heading. Options are set out overleaf, and you are advised to read them carefully and sign where appropriate and ask for a copy of the agreement for retention.

3. *Section* 5 (2).—The patient pays the maintenance cost (excluding cost of medical attention), but pays the doctor a private fee not exceeding 75 guineas. In this section you make private arrangements with the doctor regarding your medical treatment in hospitals.

On another form which patients are asked to sign on admission to a pay-bed the following statement appears:

I understand that I am entitled to free treatment at the general hospital under the National Health Service, but notwithstanding this I still desire to be admitted to the pay-bed wing on the conditions set out in the form of application for admission.

In another case the form for application for admission to the private wards is headed:

These wards are intended for the use of persons who cannot afford the fees and charges of a private nursing-home, but are able to pay for their maintenance in hospital and limited professional charges

The medical certificate accompanying the application is in the following terms:

I certify that.....is suffering from .....
and is in my opinion a fit and proper person to be received as a patient in the paying wards of the.....Hospital, in accordance with the note at the head of this form.

After announcing that the minimum payment for maintenance shall be the charge for one week, the form continues:

Where there is any doubt about the financial position of an applicant for admission an inquiry shall be conducted by the board of management as to the eligibility of the applicant

This new statement by the Ministry establishes firmly what we have always assumed to be the case—that the patient who elects to enter a private ward is responsible for the payment of professional fees.

In the announcement by the Joint Committee last week it was also stated that the Ministry had agreed that individual practitioners are free to leave untouched or to delete from the whole-time contract any of the clauses which are enclosed in square brackets. The question has been raised whether similar considerations will apply to the part-time contract. In principle the same considerations will apply to the part-time contract, but it will be appreciated that in most cases the clauses enclosed in square brackets will be fundamental to the part-time contract.

The Council

The Organization Committee is already beginning to look at some of the important issues of organization discussed at the Representative Meeting at Harrogate. At its next meeting it will discuss yet again the controversial issue of the composition and mode of election of the Council under the instruction of the Representative Body to think again on matters of detail. Certain important points of principle arising from the decision of the Harrogate meeting to increase the number of directly elected members will be considered by the Council at its first meeting in the autumn. These having been settled, the organization Committee will then proceed to work out a detailed plan for submission to the Council at its meeting early in the New Year.

DISPENSING DOCTORS

PRICING OF PRESCRIPTIONS

To reduce the heavy burden on pricing offices the Minister of Health has decided, in agreement with the B.M.A., that dispensing doctors paid on the basis of the Drug Tariff instead of by capitation fee for supplying drugs and appliances should endorse and sort their prescriptions in the same way as chemists do before surrendering them for pricing. Doctors will continue to send in their prescriptions quarterly, but will sort them for each month separately.

Endorsement and Sorting

Endorsement.—All forms bearing prescriptions for dangerous drugs are to be indelibly endorsed "D.D.A." in the top right-hand corner. Prescriptions for which "special" fees are claimed are to be endorsed "dispensed extemporaneously." Since fees for mixtures are now related to the number of doses, doctors should clearly indicate on the prescription the number of doses, the size of each dose, and the total quantity dispensed.

Sorting.—The prescriptions are to be sorted into two bundles, "S" and "A." Bundle "S" contains forms of prescriptions endorsed "D.D.A.," forms bearing "special" fee prescriptions, and forms bearing prescriptions of net ingredient cost of 5s. and over. Bundle "A" consists of prescriptions of net ingredient cost of under 5s.

Forms in bundle "A" are to be tied up in packets of 100 prescriptions, the packets being tied together in one bundle. Where the month's prescriptions exceed 2,000 or 5,000 they should be tied in packets of 200 or 500 respectively. The odd number of prescriptions left over are to be tied in a separate packet and their number shown on the packet. Bundles should be submitted with bundle "S" on top of bundle "A."

Counting.—The number of (*a*) forms and (*b*) prescriptions on these forms must be indicated in both of the bundles in which prescriptions have been sorted.

Labelling.—The two bundles bear a label showing: (*a*) the letter "S" or "A"; (*b*) the number of forms; (*c*) the number of prescriptions; (*d*) the doctor's name and address.

Invoice and Claim for Payment.—Doctors should enter on the invoice Form E.C.34 Part A the number of forms and prescriptions in each bundle, together with the grand total of forms and prescriptions for the month. They should enter on the claim for payment Form E.C.34 the total number of prescriptions for which advance payment is claimed.

Forms E.C.38 and E.C.34 Part A should be placed in that order above the two bundles and the whole tied in one parcel.

Surrender of Prescriptions.—At the end of each quarter the doctor should send the three parcels for the three months to the superintendent of the Pricing Bureau, whose address is obtainable from executive councils. The first parcel should be sent immediately after the end of September for the quarter July, August, September.

Pricing of Prescriptions

These arrangements operate from July 1. The following will be priced in full: All prescriptions (*a*) with a net ingredient cost of 5s. and over, (*b*) carrying "special" fees as indicated in the Drug Tariff, Part II 4, (*c*) carrying "D.D.A." fees, and all forms containing two or more prescriptions one of which falls within classes (*a*), (*b*), or (*c*).

At least 20% of the remaining prescriptions will be priced in full, and the balance will be paid for on the average cost of that 20%.

CONFLICT IN AUSTRALIA

The Federal Council of the B.M.A. in Australia filed a writ on July 25 in the High Court challenging the constitutional validity of the Government's free medicine scheme (*The Times*, July 25). On that date amendments to the Pharmaceutical Benefits Act became operative. They compel doctors to use State forms for prescribing free medicine.

THE NURSES BILL

Two deputations, one from the B.M.A. and the other from the Royal College of Nursing, met an all-party group of Members of the House of Commons on July 25 to discuss the Nurses Bill. That Bill has passed the Lords. The B.M.A. representatives were the following members of the Association's Special Committee on Nursing: Dr. H. Guy Dain, Dr. E. B. Brooke, Mr. A. Staveley Gough, Miss G. E. Collingwood, and Miss M. M. Edwards.

CONSERVATIVE PARTY'S POLICY

The Conservative Party has restated its policy in a pamphlet entitled "The Right Road for Britain." It states that a Conservative Government would strengthen the position of the family doctor by restoring his freedom to practise anywhere, and would give further security to doctors with small lists, particularly those in rural areas, by offering a weighted capitation fee. The Conservatives would allow private patients to obtain drugs free of charge.

They would give first place in the hospital service to reopening beds and improving the conditions for nursing staff, and they would place on all hospitals within the Service a statutory duty to admit acutely sick patients, subject to proper safeguards. A Conservative Government would reconsider whether hospitals associated with religious bodies and other voluntary organizations should remain independent if they wish to stay out of the scheme, but in general the former voluntary hospitals would be retained in the Service.

EXAMINING T.A. RECRUITS

REVISION OF SPECIALISTS' FEES

The War Office has now agreed that for the time being fees of £2 12s. 6d. and £3 5s. for one and two cases respectively will be paid to civilian specialists for examining Territorial Army recruits. Sessional fees for more than two examinations will be paid at the rate hitherto prevailing—i.e., £4 4s. for a session of 1½–2½ hours, and £2 12s. 6d. for a session of less than 1½ hours.

CERTIFICATES OF INCAPACITY GIVEN IN O.P. DEPARTMENTS

Clinics and out-patient departments of hospitals may now give certificates of incapacity to patients attending them. This has been decided by the Ministers of Health and National Insurance after consultation with the B.M.A. Formerly out-patients were often referred back to their general practitioners to obtain these certificates. That procedure put the patient's practitioner in a difficult position, since the hospital, not himself, is responsible for the treatment.

RELEASE OF MEDICAL OFFICERS FROM H.M. FORCES

The Central Medical War Committee has been notified of the following arrangements for the release of medical officers from H.M. Forces during the third quarter of 1949.

Royal Navy.—July: Group 108. August: Groups 109 and 110. September: Groups 111, 112, 113, and 114.

R.A.M.C.—June 28–July 10: Group 112. July 11–23: Group 113. July 24–Aug. 5: Group 114. Aug. 6–17: Group 115. Aug. 18–28: Group 116. Aug. 29–Sept. 8: Group 117. Sept. 9–19: Group 118. Sept. 20–27: Group 119. Sept. 28–Oct. 5: Group 120.

Royal Air Force.—July: Group 108. August: Group 110. September: Groups 112 and 114.

CONSULTANTS' MEETING

THE PERMANENT CONTRACTS

The Central Consultants and Specialists Committee met at B.M.A. House on July 20. Mr. R. L. Newell was in the chair. He told the meeting that the Joint Committee had been disturbed by the economic threat contained in the last paragraph of the letter from Sir William Douglas, of the Ministry of Health, to Sir Lionel Whitby (*Supplement*, July 16, p. 47). Sir Lionel Whitby had told the Ministry in strong terms the Joint Committee's opinion of this threat.

The Joint Committee had been advised that there was a legal distinction between the authority of Parliament and the power of a Minister. As to arbitration, the infallibility of a Minister had no place in English law. The Joint Committee had asked the Ministry for permanent machinery to be set up for the negotiation of terms of service, including remuneration. It should take the form of a medical section of the Whitley machinery. There should be agreement between the Ministry and the profession on the range of subjects that came within this machinery, and remuneration should be one of them. Discussing pay-beds, the Joint Committee had told the Ministry that it was disturbed at the Minister's apparent intention to reduce the possibilities of private practice. It had strongly objected to the words in the form of contract for whole-time officers that required them to treat private patients. The assurances received by the Joint Committee from the Ministry would be published forthwith (see *Supplement*, July 23, p. 53). Mr. Newell reported that the Joint Committee felt it essential to remain in being to take up many points that in themselves did not affect the main issue of signing or not signing the contracts.

After a long discussion the chairman moved that the committee endorse the last two sentences of the Joint Committee's statement: "The Joint Committee decided, with the assent of the Ministry, to continue negotiations on a number of outstanding points. It feels that it is now able to advise hospital staffs to enter into permanent contracts." The motion was carried by 20 votes to 6.

Representation of Registrars

A deputation of three registrars led by Dr. A. B. Backus was admitted to state a case before the committee on the representation of registrars through the machinery for representation of consultants. Dr. Backus said that there were regional associations of registrars in ten regions, and a national committee had been formed. He asked for representation of registrars on the Central Consultants and Specialists Committee and also on the regional committees. There were a number of reasons why registrars wanted this. They had not been able to obtain information about matters that affected them, particularly about grading and establishment. They sought co-ordination of problems in the hospital milieu. It would help to ensure continuity from the trainee group to the consultant group, and would help the presentation of problems peculiar to registrars. There was great financial pressure on registrars, and at present these men were far older than had been envisaged in the Spens Report. They might be forced to sign contracts before they wished to. They were seeking group structure within the B.M.A.

After the deputation had withdrawn, their case was discussed. Dr. Rowland Hill suggested that the registrars should be so organized that they were not compelled to become members of the B.M.A. Mr. Kindersley said that a sub-order of the consultants' organization should be formed for registrars. It could be discussed by a joint committee of the Central Committee and the registrars. He reminded the meeting that the Central Committee had incorporated the Hospital Committee, and therefore had the duty of representing registrars. Mr. Dickson Wright said that registrars were out of place in a consultants' committee. A recommendation of the committee's executive committee was then put to the meeting and carried —namely, that, pending further discussion on matters of detail, the representation of registrars on the regional and Central Consultants and Specialists Committees be approved in principle. A further motion was carried to the effect that there should be two registrars' representatives on the regional committees. The committee agreed to recommend to Council that a Registrars Group within the B.M.A. should be formed, and it agreed that there should be two representatives on the Central Committee—one of the Group and one from one of the regional committees.

Fighting Fund

Presenting the report of the executive committee, Dr. Rowland Hill discussed the question of a fighting fund for consultants. There were two issues for the committee to decide. First, did the consultants want to have a fund, and, secondly, did they want to have their own fund or contribute to the Guild. He advocated that deductions should be made from their pay and put into their own fund.

The committee agreed that the consultants should form their own fund. Dr. Ross Smith emphasized that there should be representatives of the consultants as such on the board of trustees of the Guild.

The executive committee will work out the details.

Appeal from Grading

The committee received a report that the Ministry has not yet accepted the Joint Committee's representations for the establishment of independent machinery. The committee decided that machinery for further appeal was necessary, and that the appeal should be heard by people other than those who have already reviewed the case.

REPORT ON MIDWIVES

COMMENTS OF B.M.A.

The Council of the British Medical Association has issued its comments on the Report of the Working Party on Midwives (A summary of the report appeared in the *Journal* of Jan. 29 p. 191.)

The Association supports many of the recommendations of the working party, but feels that there is no acute crisis in the midwifery profession. In discussing the professional relationship of midwife and doctor, the Association emphasizes that it should be made clear to both that they form a team; they have a complementary function, and neither alone can give a complete service. The report seems unsound in speaking of the midwife as a practitioner of *normal* midwifery—just as it would be unwise to call a doctor a practitioner of *abnormal* midwifery. Where doctor and midwife are working together the midwife is in no way relegated to an inferior status

A feeling of "competition" between the two professions which is tending to grow up is fostered by recommendations which attempt to define or divide up the spheres of activity of either. Clarification is necessary, and the responsible administrative bodies at all levels should clear up the misapprehension.

The Association recommends that the Central Midwives Board should drop the use of the term "maternity nurse" for a midwife working with a doctor.

The maternity services should be under continuous review by the Central Midwives Board in conjunction with the Ministry of Health.

A Maternity Services Committee should be set up, which the report recommends, but not at the regional level suggested by the report. The Association feels that these committees should cover small areas. They should contain adequate representation of all concerned in the maternity service.

Training of Midwives

Pupil midwives should be recruited only from State-registered nurses. This conflicts with the report's statement that "provided her training is suitable there is no inherent reason why a midwife should also be an S.R.N."

The report states that the midwife must have a thorough knowledge of nursing techniques. The Association considers that she must also be fully trained to work in loyal partnership with the medical profession, and her qualifications and training must be such as to command the respect of both doctors and laity. The training of non-State-registered nursing staff as pupil

midwives gives far more trouble than is justified by the results. The Association is averse to introducing obstetrics too early into a course of general nursing. The report advocated four weeks' obstetric training early in the course, but experience shows that many women dislike obstetrics at their first experience, and its inclusion early in the curriculum may hinder recruitment.

Questions Answered

Payment of Expenses

Q.—*Before July 5, 1948, I was a full-time radiologist of a voluntary hospital receiving a salary and a share of fees in respect of private practice carried out in the hospital. My contract with the hospital provided for the payment of my expenses for attendance at clinical meetings. Since July 5, 1948, I have continued my clinical visits for six months, but in December, 1948, I was informed by the regional board through their deputy administrative medical officer that payment of such expenses was a matter of discussion with the Ministry. At a later date my basic salary was increased as an interim measure, and I was informed that in view of this any expenses claimed under my former contract would no longer be allowed. In actual fact no expenses have been paid since July 5. Is it your opinion that I can press this claim?*

A.—Although it is true that whole-time salaried hospital officers were transferred on the appointed day without a new contract and on the same terms as previously, this was an interim arrangement pending the settlement of permanent terms and conditions of service. In the meantime the Ministry has effected changes in individual circumstances—e.g., as in the case of car expenses—to bring them into line with the general pattern. The permanent terms will be applied retrospectively, and therefore it would serve no purpose to press for certain payments which might not be allowable under the final terms. The Ministry's proposals regarding study leave (which includes leave to attend conferences and scientific meetings) are set out in the terms (*Supplement*, June 11, p. 314).

Permission for Partnership

Q.—*Can I take a neighbouring practitioner into partnership without reference to the local medical committee? If I do take him into partnership, and if I retire in four to five years, can he automatically take my practice—again without reference to the committee? We are both in the Health Service.*

A.—If the neighbouring practitioner is already on the list it is not necessary for permission to be obtained from the local executive council in order that he may join you in partnership. If the practitioner is not on the list the consent of the Medical Practices Committee for inclusion on the list is necessary before he can join you in partnership. Should you retire in four or five years your partner would have no automatic right to your practice. The executive council will take into account a retiring principal's views as to his successor, but it is for the council to decide what advice it will give to the Medical Practices Committee as to the filling of the vacancy.

Residence and Place of Practice

Q.—*Are there any Health Service regulations limiting the distance at which a general practitioner may reside from his surgery, there being a full-time caretaker at the surgery?*

A.—Yes, a practitioner may not carry on practice elsewhere than at his place of residence or at a health centre, except upon conditions which appear to the local executive council, or on appeal to the Minister, to be such as to enable his obligations under his terms of service, and in particular his obligation to visit his patients, to be adequately carried out. A practitioner is required to attend and treat at the places, on the days, and at the hours to be arranged to the satisfaction of the council.

Private Certificates for Workmen

Q.—(*a*) *Can the doctor charge for issuing to workmen private certificates for their employers or private insurance clubs as regards the workmen's ability or inability to follow their employment?*

(*b*) *Are there any special arrangements in this respect for workpeople working under the Coal Board?*

A.—(*a*) Yes. A doctor can charge a fee for private certificates for incapacity for work. During the war a special form of certificate was issued by the Ministry of Labour and National Insurance (E.D. 652) on which appears the statement that a fee is payable.

(*b*) In some areas collieries and other firms use a special form of certificate. Doctors may be asked to co-operate by using these forms, but they are under no obligation to do so.

Retrospective Terms

Q.—*In March, 1948, I took my Diploma in Medical Radiodiagnosis. Having been a registrar (supernumerary) at a hospital, and knowing them to be short of staff, I offered my services. I was offered, and accepted, the post of assistant radiologist, locumtenent, and took up my duties on June 1, 1948. I still hold the appointment. I now understand that my status has been assessed and that I will fall into one of the "trainee specialist" groups. Referring to para. 5 (a) in "The Proposed Terms and Conditions of Service of Hospital Medical and Dental Staff," can I not claim payment on such a scale from July 5, 1948, and until the termination of my present appointment?*

A.—In its Explanatory Memorandum on the terms of service for hospital medical staff (*Supplement*, June 11, p. 321) the Ministry of Health indicated that it was the intention that, so far as possible, the terms should apply retrospectively to the appointed day. It is reasonable to assume, therefore, that the questioner would be remunerated in respect of the appointment which he has held since the appointed day and as from that date in accordance with his grading.

HEARD AT HEADQUARTERS

Big Agenda

The old Insurance Acts Committee, which generally had more to do than any other Headquarters committee, managed as a rule to get through its business in an afternoon. The General Medical Services Committee, which is its successor, and represents the general practice side of the National Health Service, is finding it necessary to have all-day meetings, so great is the pressure of business and so manifold the questions which arise. At their meeting the other day the members had eleven documents before them. The shortest must have run to a couple of thousand words, and the agenda contained 48 items. The committee sat at its task from 11 a.m. to 6 p.m. It was hoped, in the absence of any emergency development, to have a summer recess, with the next meeting in September, but on looking at its programme the committee found it necessary to meet again at the end of July. The chairmanship of such a committee is on the way to becoming a whole-time job. The same is true of the Consultants and Specialists Committee, which needs a day for its meetings.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Correspondence

Whole-time Hospital Medical Officers

SIR,—We are writing, one a whole-time hospital medical officer and the other a general practitioner, in the hope of stimulating among doctors but a fragment of the mutual loyalty among dockers.

Now we learn of the blatant unfairness with which whole-time hospital medical officers are to be dealt, as revealed recently by the Ministry of Health in the terms and conditions of service of hospital medical and dental officers (*Supplement*, June 11, p. 314). Para. 5 of this document discloses that for part-time medical officers each so-called notional half-day of up to 3½ hours, in which is included time travelling to the hospital, will count for one-eleventh of the appropriate full-time salary. For 31½ hours worked and travelled, a maximum of 9½ elevenths will be paid. In addition, they can earn up to 800 guineas annually for domiciliary consultations (about 4 weekly), which whole-time officers will perform unpaid (para. 8).

Nowhere does this document define the limit of whole-time officers' hours of work, though, with Civil Service devotion, other obligations and restrictions are enumerated, but, by analogy to the part-time scales, a full-time week of eleven half-days should be 38½ hours. In fact, all full-time medical officers do far longer hours than this with one or more 24-hour spells of duty each week and regular week-end duties of 48 hours tied to the hospital and away from their families.

It reflects on the lack of solidarity in the profession and on the quality of its negotiators that such shabby discrimination against those who bear the burden of the hospital services is tolerated for a moment, that the hourly rate of pay for whole-time officers should be so very much less than for part-time colleagues, and that their hours of work be unrestricted, without pay for overtime and night and week-end duty. It is surely reasonable to demand parity of treatment for whole- and part-time medical officers, especially in face of the Minister's wish to attract the best people to whole-time service.

It is also strange indeed that, the swindle of the senior hospital medical officer status having been permitted, his *maximum* salary as an acknowledged specialist should, without protest, be £28 per annum less than the income Mr. Bevan hopes the average dentist will have after 52% is deducted for expenses.

Whole-time hospital staffs still have an opportunity to attend *en bloc* their local B.M.A. Branches, where there are numbers of frustrated general practitioners awaiting any sign of encouragement and concerted action. An alliance in only a few Branches could turn the machinery of the B.M.A. towards doing something urgently for these two groups and challenge the Ministry to maintain the N.H.S. without them if their grievances are not met.

The alternative is to go on swallowing the betterment factor, the 4d. a week per head encouraging the minimum attention as economically advantageous, for the G.P. no paid holiday or sickness locums, the mileage scandals and whatever next may come, as well as the bitterness of watching the local oculist test his patients' eyes and the dentist fill a tooth for as much as he earns looking after the patient for the whole year. —We are, etc.,

HAROLD BOURNE.
E. B. ALLEN.

Virginia Water, Surrey.

Tuberculosis Group

SIR,—Now that formation of a Tuberculosis Group has been sanctioned by Council, it is to be hoped that the inaugural meeting will be held as early as possible. This group can be of great value to doctors working in the tuberculosis field if the committee is really representative of all regions and of all sections, including registrars.

I hope that the inaugural meeting agree with this view, and that a strong committee will be elected.—I am, etc.,

V. COTTON CORNWALL.

Liverpool.

Dental Anaesthetics

SIR,—I should like to draw attention to the position of payments for dental anaesthetics.

We are paid for extractions of up to three teeth only 10s., independently of what kind the anaesthetic is. I am asked in the majority of cases to administer "pentothal." One gramme of pentothal costs 3s. 6d., so we are left with 6s. 6d. for a full anaesthetic involving often a mileage of over two miles and at least one hour's time.

Disregarding the responsibility involved and the skill required, the payment is much lower than that of an unskilled labourer. My dental colleagues inform me that many doctors are not prepared to give anaesthetics unless in sessions, and are principally reluctant to give intravenous anaesthesia. No wonder! —I am, etc.,

H. MARGULIES.

London, N.W.2.

Grading of Hospital Staff

SIR,—Many letters recently published show the very real dissatisfaction that exists regarding the creation of senior hospital medical officers. Surgeons, physicians, and anaesthetists, many of whom have higher degrees, years of experience, recognition by their colleagues as specialists, and are on the staff of recognized hospitals, are being relegated to this status. Ability seems to have no bearing upon the matter. Their great sin is that they participate in general practice.

One point has not been made clear, and it is that the S.H.M.O. was suggested by our representatives and offered to the Minister, who readily accepted it as a convenient method of "cheese-paring." So the blame rests this time not so much upon the Minister but upon those colleagues of ours whom we delegated to watch over our interests. Surely a matter of such importance should have been put to the profession as a whole, which could then have decided in true democratic fashion. If the machinery of the B.M.A. is impotent to right this wrong, then resignation from the employment of the regional hospital board is our most effective weapon.—I am, etc.,

GUY STEELE-PERKINS.

Exeter.

Rate of Payment

SIR,—Surely the answer to Mr. Donald M. O'Connor's letter (*Supplement*, July 9, p. 46) and to the appended comment by the Secretary of the Association is that, as soon as our lists have been cleared, we should press for fixed universal payments and for the abolition of the central pool. Let us all have fixed capitation fees, mileage, and temporary resident fees. This would mean an end of the pool, that bottomless pit from which everything seems to be frittered away before it reaches the practitioner. Then at least we should know where we stand from one quarter to the next.

This should require no magic financial jugglery to budget for. We already have fixed fees for maternity work, and the dentists, opticians, and pharmacists have fixed payments for items of service. It should be far easier to anticipate the sum likely to be involved in our case than in any of these other cases.—I am, etc.,

D. R. MACDONALD.

Inverness.

General-practitioner Consultants

SIR,—I am sorry that Mr. Richard de Soldenhoff (*Supplement*, July 16, p. 51) formed the opinion that Dr. T. N. Rudd and I had deliberately left out the fact that G.P. consultants are paid for their State services, and that he seemed to feel that a concealed desire to retain monetary advantages was a strong motive behind our attempt to put the case for those who practise medicine as we do. We thought that everyone would know that payment was being made for our State services and felt sure that, had he not been a whole-time specialist, he would have realized only too well that loss of private practice has, almost everywhere, far outweighed any income that is now received from State sources.

I am sorry, too, that he considers our arguments specious, and I would like to take this opportunity to try to assure

him that it was a very genuine effort on our part to put the case for a way of life and a method of service to which we are devoted and in which we whole-heartedly believe. We do not wish to be involved in any invidious arguments about relative efficiency, but we believe that, in the straightforward cases in which we endeavour to give our best, the relative advantage of a possible loss of a slight degree of efficiency is far more than balanced by the increased human handling, born of close contact and personal acquaintance.

With regard to his strong point about efficiency: perhaps it will suffice to say that no treatment is undertaken unless we feel quite sure the experience available to us makes us competent to perform it efficiently; otherwise it is readily passed on to other hospitals and specialists more expert in those cases than ourselves. This the G.P. consultant has to do to safeguard his local reputation.

I trust he and others in the profession will think again before damning to eventual extinction a section of his profession which he admits has rendered valuable and irreplaceable service, and will allow us a chance to make our full and honest contribution to personal medical service.—I am, etc.,

Tiverton, Devon. GEORGE LOWE.

His Own Doctor

SIR,—The ruling that doctors may not prescribe for themselves under the N.H.S. is a type of restriction which will only embitter the profession still more against the Service. It is a petty and unnecessary regulation, which suggests either that we are no longer to be regarded as professional men and women of integrity with a sense of responsibility or that most of us are potential drug addicts.

It has always been the custom for us to treat ourselves for all ordinary ailments, only calling on our colleagues for those that are more serious or when we feel that the responsibility would be shared or lifted. After all, if there is evidence that we have over-prescribed, the Minister has a remedy. This is a fatuous ruling which should be resisted on principle.

Are we expected still further to subsidize the Service—as if we had not done enough already—by buying our own remedies, or are we to put notices outside our waiting-room doors: "Surgery closed—Doctor has gone to his own doctor to obtain a prescription for a bottle of linctus"?—I am, etc.,

London, S.W.19. A. D. BELILIOS.

H.M. Forces Appointments

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Captains F. W. Newby-Good, E. J. Ewell, G. V. Cole, A. M. Stalker, and J. D. Finnegan have been granted the acting rank of Major.

Lieutenants G. A. Bell, R. Semple, S. R. F. Whittaker, C. T. A. Burgess, O.B.E., J. P. Mitchell, P. M. Davies, F. C. Garrow, and R. W. Biagi to be Captains, and have been granted the acting rank of Major.

J. F. Philip to be Lieutenant, and has been granted the acting rank of Major.

REGULAR ARMY: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Captains C. W. G. Cough and I. B. Sen Gupta have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captains J. W. Doupe, T. R. Morley, G. H. Henry, and A. G. Richards have relinquished their commissions and have been granted the honorary rank of Major.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: W. R. G. Thomas, M.B., Medical Officer, Tanganyika; J. Goodey, M.R.C.S., Medical Officer, Specialist (Temporary), Jamaica; Miss E. W. Smith, M.B., D.M.R.E., Radiologist, Barbados General Hospital; R. S. Johnston, M.B., D.T.M.&H., D.P.H., J. C. Milne, M.B., D.T.M.&H., D.P.H., and C. H. Williams, M.B., D.T.M.&H., D.P.H., Superscale Medical Officers, Grade A, Federation of Malaya; R. E. Anderson, M.B., D.T.M.&H., D.P.H., H. Scrimgeour, M.B., D.T.M.&H., and T. F. Strang, M.B., Superscale Medical Officers, Grade B, Federation of Malaya; C. E. Bevan, M.R.C.S., D.T.M.&H., Medical Officer Specialist (Tuberculosis), Cyprus; A. C. E. Cole, M.D., M.R.C.P., D.T.M.&H., Medical Specialist, Tanganyika; J. W. Field, M.D., Director of the Institute of Medical Research, Federation of Malaya; R. B. Heisch, M.B., Senior Pathologist, Kenya; J. F. MacDonald, F.R.C.S., Senior Specialist (Surgical), Northern Rhodesia; D. J. M. Mackenzie, M.B., Director of Medical Services, Nyasaland; J. Taylor, M.B., D.T.M.&H., D.P.H., Medical Officer of Health, Fiji; E. M. McLean, M.D., Medical Officer, Grade B, Trinidad; L. A. H. McShine, M.B., Medical Officer, Grade A, Trinidad; M. S. Sindhu, F.R.C.S., Medical Officer, Aden.

Association Notices

AREAS OF HOLLAND AND LINCOLN DIVISIONS

Notice is hereby given by the Council to all concerned that it is proposed to transfer the following areas from the Lincoln to the Holland Division:

Urban District of Skegness.

That part of the R.D. of Spilsby comprising the Civil Parishes of Wainfleet all Saints, Friskney, Stickney, Croft, New Leake, Eastville.

Any member affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by Aug. 27, 1949, stating the objection and the ground therefor.

CHARLES HILL,
Secretary.

ADJUSTMENT OF AREAS OF CORNWALL AND PLYMOUTH DIVISIONS

Notice is hereby given by the Council of the following proposal made by the Plymouth Division:

That the Urban Districts of Torpoint, Looe, and Callington, the Municipal Boroughs of Saltash and Liskeard, and the Rural Districts of St. Germans, Calstock, Liskeard, and Launceston be transferred from the Cornwall Division to the Plymouth Division.

Any member or Division affected by the proposed changes and objecting thereto should write to the Secretary of the Association by Aug. 30, 1949, stating the objection and the grounds therefor.

CHARLES HILL,
Secretary.

Meetings of Branches and Divisions

BOLTON DIVISION

The annual general meeting of the Bolton Division resolved to circularize all practitioners in the area about the B.M.A. policy concerning Public Health Service:

"The Association has made repeated attempts during recent months to open negotiations on permanent scales of remuneration for medical officers in the Public Health Service. Owing to the unwillingness of local authorities to begin discussions under the machinery recommended by the Government for this purpose, the Council is not prepared to accept local authority advertisements for publication in the *British Medical Journal* unless the salaries offered are in conformity with the Association's own proposals.

"It is believed that some local authorities contemplate approaching general practitioners to undertake extra part-time duties and thus cover the work normally falling within the province of a whole-time medical officer. A strong appeal is made on behalf of the Council of the Branch to general practitioners to decline such offers.

"Inherent in this dispute with the local authorities is the question of compulsory arbitration, an issue of crucial importance to the general practitioner as well as to the public health medical officer. If every member of the profession co-operates by declining to apply for, or to accept, any appointment of the kind referred to in this note, the day when negotiations can be opened will be appreciably hastened."

SURREY BRANCH

The following officers were elected at the annual general meeting on June 22. President: Dr. L. J. Barford. President-elect: Dr. S. A. Forbes. Vice-presidents: Dr. R. R. Powell and Mr. R. M. Savege. Hon. secretary and treasurer: Dr. J. W. Starkey. Hon. auditor: Dr. H. R. Cran. Public health representatives: Dr. K. A. Soutar and Dr. S. L. Wright.

Correction

In our report of the Roman Catholic service held at Harrogate on June 30 (*Supplement*, July 9, p. 41) we incorrectly said that the address was given by the Bishop of Leeds. In fact it was given by the Reverend H. P. Hennelly.

TUBERCULOSIS: CERTAIN UNEXPLAINED MORTALITY FIGURES*

BY

The Right Hon. WALTER ELLIOT, *M.C.*, F.R.C.P., F.R.S., M.P.

I want here to deal with a subject which necessarily involves statistical tables and the scrutiny of certain factors of incidence of disease. I am well aware of the desirability of the very greatest and closest attention to these things in detail and for the most meticulous accuracy. Therefore I am afraid that on this occasion I must add the letters with which we are not unfamiliar in the scrutiny of accounts—E. and O.E.—"errors and omissions excepted." You must in fact take this more as a general survey than as a very close scientific examination—all the more so since the factors with which I am dealing are not anywhere fully explained, and are not at the moment the subject of any consensus of scientific opinion. I draw attention to the trends; the conclusions to be drawn are admittedly extremely hypothetical. I wish to discuss the figures representing a certain unexplained mortality in tuberculosis, particularly pulmonary tuberculosis, in the northern half of Great Britain, and more particularly in Scotland. Scotland is a very convenient statistical unit from many points of view; it is a smaller and more manageable country, and its figures are sometimes published ahead of the corresponding figures for England.

Tuberculosis Rates

Tuberculosis rates are, it is agreed, among the most important indices of the state of the public health. I think it will be agreed that the steady fall in tuberculosis mortality in the United Kingdom has been a notable feature of public health figures for many years. The rates for pulmonary and for non-pulmonary tuberculosis each have their special significance. For my purpose it is desirable to examine them separately, where possible, although the combined rates have also, of course, great importance.

Just to run over the background picture. The death rate for pulmonary tuberculosis per 1,000 of the estimated population was, in 1851, for England and Wales, 2.78. In the next 45 years it fell to almost exactly half: it was 1.34 in 1897 and 1.31 in 1898. The fall continued. By 1910 the rate had dropped to 1.02 and by 1920 to 0.87, in spite of the war. The fall still continued; in 1930 it was 0.72; in 1938, before the outbreak of the last war, it was 0.52. These figures follow the recognized course, a course which finds a general parallel in many other countries, even in those greatly ravaged by war and suffering in consequence from various degrees of malnutrition and overcrowding.

There was a short and slight rise of the figures in England and Wales in the early war years, but the rise was neither alarming nor continued. The unexplained figures to which I should like to draw attention are those for Scotland. The curves in the two countries for many years followed the same general course. The death rate per 1,000 for pulmonary tuberculosis in England and Wales was, for example, 0.72 in 1931. In Scotland it was 0.62. In 1938, when, as I have said, the rate in England and Wales was 0.52, the rate in Scotland was also 0.52; that is to say, the falling rate in England had gone faster than in Scotland, and the two were at the same point. The rate in Scotland, however, reacted to 0.63 in 1941, and continued at 0.62 for 1942, 1943, and 1944. This was all the more strange since the destruction of houses owing to aerial bombardment was very much greater in England than in Scotland, and the regular crowding together of the population by night in air-raid shelters, which was such a feature in London during the blitz, had no parallel in Scotland. The Ministry of Health viewed with very great apprehension the result of those enormous numbers of people herding together at night, and sleeping in crowded shelters, out of their homes, during the war years.

Increase of Pulmonary Tuberculosis in Scotland

In 1945, at the end of the war, the Scottish pulmonary tuberculosis rate declined to 60 per estimated 100,000. It appeared to be about to follow the decline which was taking place in England, but this was not borne out by events. The estimated rate for 1947 rose to 66 per 100,000, and this figure was repeated in 1948. No figure so high has been recorded in Scotland for 20 years.

These figures do not seem to be due to any statistical fallacy. Notifications may be, and are, subject to changes due to greater accuracy in diagnosis and to the extensive use of *x*-ray surveys. In an *x*-ray survey among the students of one large city in Scotland, of the total examined—3,465—the rate of significant tuberculosis detected was: for females, 1.95 per 1,000, and for males 2 per 1,000. A statement issued by the Ministry of Health in March, 1949 (*British Medical Journal*, 1949, 1, 493), said that by June 30, 1948, about 2,500,000 persons had been examined by mass radiography. The number of cases in which clinical diagnosis of active tuberculosis was subsequently made was approximately 9,564, or between 3 and 4 per 1,000 of all persons examined. It is not more than one would expect. The post-war notifications cannot be exactly compared with those of the pre-war years; but I think the post-war notifications can quite justly be compared with each other, and, taken in conjunction with the actual deaths, they present this feature of a rise in pulmonary tuberculosis in which Scotland is exceptional.

In 1945 the notifications in Scotland, which pre-war had been 4,700, rose to 7,300. As I say, a certain proportion of that has to be discounted owing to greater accuracy in diagnosis, but not all of it. In 1946 the notifications

*Presidential address to the Royal Institute of Public Health and Hygiene given on Thursday, May 26.

were 7,627; in 1947, 7,984; and in 1948, 8,208. The deaths follow a similar curve. The deaths from pulmonary tuberculosis in Scotland—and that is as near a watertight statistical figure as you can get, for people are not certified as having died from pulmonary tuberculosis unless there is a fairly strong certainty that that is the cause of death—in 1945 were 2,932; in 1946, 3,231; in 1947, 3,390; and in 1948, 3,417. It is clear, therefore, that the upward trend of notifications is followed to a certain extent by an upward trend of deaths. In 1948, as I have pointed out, the figures are the highest yet; and the 1948 figures are important because they refer to a year with an exceptionally mild winter, as against the exceptionally severe one of 1946–7, which might reasonably have been expected to produce a rise in pulmonary disease of all kinds. The curves are shown in Fig. 1. The figures for respiratory and non-respiratory tuberculosis move quite reasonably until 1939. Then there is a startling rise in notifications of cases of respiratory tuberculosis, and the curve runs on to a plateau. There is no sign whatever of a movement downward. The mortality rate for respiratory tuberculosis follows the notification rate upwards at a short distance.

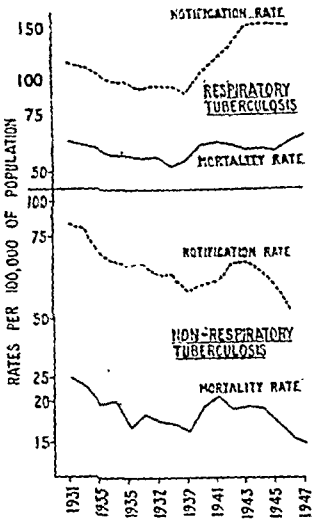

FIG. 1.—Notification and mortality rates of respiratory tuberculosis compared with those of non-respiratory tuberculosis in Scotland.

In contrast to the pulmonary tuberculosis rate, the non-pulmonary tuberculosis rate shows a drop both in number of notifications and mortality. It seems as though after a period of time the curve were resuming its normal shape. I need not remind you of the intense campaign being waged for the purification of milk. It will be seen, therefore, why I decided that it was more advantageous to examine those two curves separately, not combining the curve for the pulmonary cases with that for the non-pulmonary. In that way there will be no misleading conclusions.

Decline in England and Wales

The interesting thing is that this rise is not parallel in the general statistics south of the Border. In England and Wales the notifications of pulmonary tuberculosis were: in 1945, 42,100; 1946, 42,100 (I am leaving out the last two digits); 1947, 43,100; 1948, 43,900, a slight rise. These figures are only to be compared with each other; it is not so useful to compare closely the figures for England with those for Scotland, because the details are different. On the other hand, the deaths were: in 1945, 20,013; 1946, 19,365; 1947, 20,156; 1948, 19,089. It is clear that something quite different is happening in the two countries, and the really interesting question is. Does it stop at the Cheviots, at the artificial political frontier, or not? A striking difference would not be expected between Newcastle and Galashiels and between Lancashire and Lanarkshire.

At this point it is interesting to note that the Scottish figures are high amongst European countries, whilst the English figures are low. We are dealing here not merely with a rise but with a rise in a country with a high tuberculosis figure. In England we are dealing with a fall in a country with a low tuberculosis figure. The most recent death rates from all forms of tuberculosis per 1,000 are as follows: Denmark, in 1946, 32; New Zealand, in 1945, 38; United States, in 1945, 40; Sweden, in 1946, 51; England and Wales, in 1946, 55; Belgium, 66; Switzerland, 76; Scotland, 79; France, 81; Northern Ireland, 83. It will be seen that even in 1946 there was a wide gap between the rate in Scotland (79) and the rate in England and Wales (55). A breakdown of these figures amongst the Scottish towns shows a very high figure in the great industrial centre of Glasgow, and to a smaller extent in Dundee, while Edinburgh is lower, and Aberdeen, surprisingly enough, is lower still. The industrial County of Lanarkshire follows Glasgow. Caithness and Orkney follow Aberdeen. In 1946 the death rate per 100,000 for all forms of tuberculosis was: in Aberdeen 46, in Edinburgh 76, in Dundee 87, and in Glasgow 132. This compares with figures of 42 for New York, 44 for Copenhagen, 51 for Amsterdam, 56 for Stockholm, 78 for Paris, and 110 for Madrid. The rate for Glasgow was a long way above the rate for Madrid.

I have set out here, by courtesy of the Department of Health for Scotland (to whom I am also indebted for the graphs of Fig. 1), the run of the curve as you might have expected it and the run of the curve as it is actually working out (Fig. 2). The curve plotted out from 1931

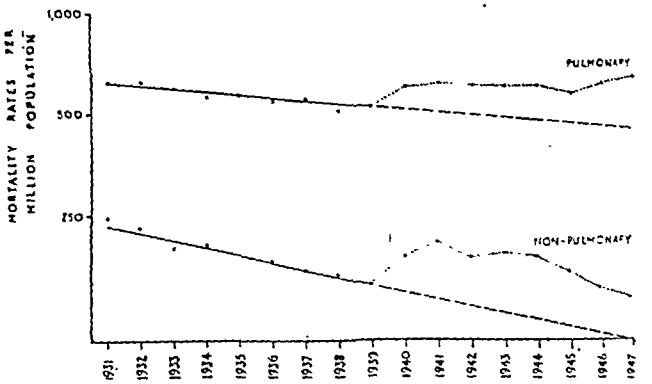

FIG. 2.—Graph showing mortality rates of tuberculosis in Scotland, together with expected curve from 1939–47.

is projected (broken line) on to 1947, with the figures on either side of the line up to this rise of which I have been speaking. The projected line shows how the figures ought to have gone; the dotted line shows how they actually went. The non-pulmonary curve, according to the latest figures, has a trend satisfactorily downwards along the projection, but the pulmonary curve has a trend upwards, away from the projected line.

"Slope to the North"

To come to the next point of which I spoke, the question of the English figures, can we draw any conclusions from an analysis of the figures in England? I believe it is true to say that a "slope to the north" can be discerned. The rate for all forms of tuberculosis in 1946 was 66 in Birmingham, 79 in Manchester, 89 in Liverpool, and 92 in Newcastle. I think it is clear, therefore, that a certain masking of the trends in England is taking place, owing to the averaging of the north and south. It is still more interesting that in the northern areas the rates have tended to rise and this at a time when the overall rate in England and Wales has continued to fall. As I have said, it would be very queer if completely different trends were shown in Lancashire as against Lanarkshire. The deaths per 100,000 from pulmonary tuberculosis in Lancashire were 70.9 in

1945, 75.1 in 1946, and 76.1 in 1947. The same trend shows in the West Riding of Yorkshire, a county with a great population which can give one a reasonably reliable statistical figure. It is a lower rate, but lately it has moved upwards. That is all the more interesting, since the West Riding figures for the last 50 years or so have been below the average of England and Wales. They are at present tending to rise. The rate was 54.9 in 1945, 53.7 in 1946, and 58.8 in 1947. For Durham County the figures are: 43.0 in 1945, 41.4 in 1946, and 47.4 in 1947.

I do not wish to lay too much emphasis on this trend, because I have not the 1948 figures for those counties, and all these figures may still be distorted by the incidence of the very long and severe winter. In Scotland, as we saw, they have been able to cross the bridge and to give figures for the following year, when the winter was mild. I would therefore not lay too much stress on the rise that occurred in the three northern English counties mentioned. On the other hand, it is true that even in those severe winters this rise did not take place in other areas. It did not take place in Northern Ireland, though the figures there are high, nor in the City of Belfast: nor has it taken place to the same extent in either the cities or the counties of Wales.

Of course in Northern Ireland we are dealing with smaller figures, but there the actual deaths from pulmonary tuberculosis were 799 in 1945, 849 in 1946, and 761 in 1947; and in Belfast 328 in 1945, 343 in 1946, and 281 in 1947. It also is rather odd that the rise did not show itself in the cities or the counties of Wales. In a very great industrial centre such as South Wales roughly the same trend would be expected as is found in Liverpool and in Glasgow. In Glamorgan County the actual deaths were 416 in 1945, 432 in 1946, and 432 in 1947; in Cardiff the actual deaths were 178 in 1945, 164 in 1946, and 161 in 1947. We all know the fallacy of small numbers either in death rates or in any other form of statistical analysis. I do not wish to stress these figures, but it certainly would not be true to say that in them you can detect a rise.

Causes of Upward Trend

Now it is very difficult to see what factors can have changed adversely in the industrial North which have not changed in industrial Wales or in industrial Southern England. What is affecting Glasgow which is not affecting Birmingham and Cardiff? The factor, whatever it is, seems to be associated elsewhere at least with industrialism. The rise in Scotland is mostly in Glasgow and Lanarkshire. The upward trend in Northern England is shown in the industrial counties of Durham, Lancashire, and the West Riding. It is not shown in the neighbouring more-agricultural counties of Northumberland and Cumberland. On the other hand, no rise at all is shown in Sheffield or Leeds. The housing conditions in the northern towns in general have been worse than those in the south, yet one might say that the deterioration, if anything, was greater in Birmingham, Manchester, and, of course, London, all of which suffered wide destruction of houses from air bombardment.

There is another factor which might have to be examined —not so much a deterioration as an equalization. The rationing system has tended to level out any differences in consumption of food and fuel. I think it is probable that, pre-war, there was a greater consumption of food and fuel as one moved northwards. At any rate, the housing was worse, and in general the rents were lower and the surplus available for food was greater. It is possible that the ironing out of these things has increased the impact of climate and housing, and that that is at least partly responsible for the figures I am mentioning.

As you know, the Secretary of State for Scotland has actually instituted an inquiry into the Scottish position. The committee in question has not yet reported, and I think that its first report will be mainly of a factual nature. So far as I know, this committee has not yet arrived at any explanation. And so the fascinating picture is before you of a detective story half read. We do not know the criminal. It is up to us to exercise our intelligence. The field is open; anyone may gain great fame and reputation by solving the puzzle. It is a very remarkable thing in the history of public health that one of the major diseases, one which has been under such careful examination for so many years and has been so closely surveyed in every way, is at present subject to a movement that is entirely unexplained by those who have either the responsibility of dealing with it or the responsibility of giving advice upon it. From the administrative point of view this problem has, naturally, to me the very highest fascination.

Non-respiratory Tuberculosis

I promised to mention the non-respiratory curve. That curve has moved down, as one would expect, I think, *parallel with the "cleaning up of the herds."* It was, however, puzzling to us in Scotland that our figures remained above those of England, although the cleaning up of the herds has gone much farther in Scotland than in England. That story, however, so far has a happy ending, because the most recent figures of 1948 show that the curve has come down with a run and is only just above that for England. The non-respiratory mortality rate, which in England and Wales was 10 in 1945, 8 in 1946, and 8 in 1947, left us with an unexplained problem in Scotland, where it was 18 in 1945, 15 in 1946, and 14 in 1947. However, the 1948 figure comes down with a run to 9, so it looks as if wisdom were being justified of her children there. But that simply means that that curve is doing what one would expect—it is following a recognized course, the campaign is producing results.

Conclusion

To summarize, the fascinating curve is the one which is not doing what we expect, which is moving the other way—the campaign is not producing results. A doubly interesting point is that in England, where the combination of the various parts of the island is producing a general curve, it would appear, breaking it down more closely, that the curve is not similar in all parts of the Kingdom. Wild speculations may be made; they are as likely to be right, or at any rate to form as reasonable a point of departure, as any other at the moment. One speculation is that there may have been an introduction of a more active strain of infection into Scotland in the considerable Polish migration that took place in the early days of the war. It may not be so; but, at any rate, there certainly was a mass movement to our country of a population which in its own country is highly susceptible to tuberculosis and has a high tuberculosis rate—a population which afterwards was intermingled very intensively with the Scottish people. That may be an entirely erroneous line of inquiry. But when you are faced with an unexplained set of facts you must consider all the likely and all the unlikely explanations. It is possible that the unlikely explanations are quite as right as the likely explanations. Here, then, is a fascinating problem of public health to which no solution has yet been found. I commend it as an example of how to-day it is still possible to find unexplained problems, and of how it may be possible, by the use of intelligence and by industry, for any investigator to find an explanation of facts which so far have baffled everyone.

PROBLEMS OF AGEING AND CHRONIC SICKNESS*

BY

A. P. THOMSON, *M.C.*, M.D., F.R.C.P.

Professor of Therapeutics, University of Birmingham; Physician, United Hospitals, Birmingham

In my first lecture I recalled impressions gathered from a general review of several infirmaries and presented a more detailed analysis of the patients of one large institution. Before I discuss the clinical material as a whole I propose to describe some conditions that deserve more attention than they have hitherto received. They fall into four groups: (1) Extreme contractures developing without apparent lesions in either the nervous or the locomotor system. (2) Some peculiar conditions of the feet. (3) Unusual phenomena in the late stages of vascular hemiplegia. (4) Incontinence.

Contractures

The contractures to which I would draw attention are usually found in very old people who have been long in bed. The posture is one of extreme flexion; the knees are drawn up to the abdomen, the heels touch the buttocks, the arms are held close to the sides, with the elbows bent so that the hands are close to the mouth, and the chin rests on the chest. The wrists and fingers and sometimes one elbow are freely movable; when feeding, either hand is used to stuff food into the mouth without the help of spoon or fork. The attitude recalls that of the intrauterine foetus. Such patients are difficult to examine. Left to themselves they pull the bedclothes over their faces and lie motionless for hours. In all that we have examined we have found the plantar responses flexor, but it was hardly possible to be certain of the tendon reflexes. Rough testing of sensation showed no gross change, but vibration sense was absent. Attempts to straighten the limbs were obviously painful.

There was no history of arthritis or any detectable abnormality in the joints. A few of these old people talked freely and sensibly when they were roused, but they certainly preferred to be left alone. Invariably they were totally incontinent.

We speculated much about the cause of this condition, which I had never encountered before; it may be that there is some degeneration in the central nervous system that accounts for it, but the extraordinary agility of the fingers of both hands in manipulating food makes that explanation improbable. Eventually we came to the conclusion that the very old adopt a position of flexion in bed in order to conserve heat; for the same reason they pull the bedclothes over their heads and rebreathe their expired air. In the course of time the immobile muscles are fixed in one position. It is likely that regular massage and passive movement would prevent this horrible and distressing distortion. If, as is common in cases of arthritis, the contracture of the legs is not symmetrical and one thigh rests across the other, extraordinary atrophy of the soft tissues occurs at the place of pressure, so that the femur may be felt almost immediately beneath the skin on the medial aspect of the thighs. The tissues adjacent to the place of contact seem to be moulded round the opposite limb.

*The second of two Lumleian Lectures delivered at the Royal College of Physicians of London on April 5 and 7. Lecture I was published in last week's issue.

The Feet

The deplorable condition of the feet of the aged poor is notorious. On admission to the infirmaries many patients have deformities not only of the toes and feet but also of the nails which must have made walking painful. In some the nails grow to such an extent that they are bent over by the shoe and bury themselves in the soft tissues on the under side of the toe. Relief of this distress by rest in bed leads some of them to avoid activity, and soon they become permanently bedridden. We have no doubt that the deformities are increased, and in a few cases caused, by the pressure of bedclothes tightly tucked in. In many patients lying supine we found the terminal phalangeal joints flexed with the skin shiny from the pressure of the sheet; the great toe later is inclined outwards, usually on the dorsal aspect of the foot in the position of extreme hallux valgus, but sometimes it is pressed under the other toes and comes to lie on the ball of the foot so that when the patient tries to stand the weight is borne on it.

As an example to show how so simple a deformity may wreck an individual life I recite this simple history.

A woman aged 58, in active work in a factory in 1940, fell and broke her humerus. She was admitted to hospital; there was some difficulty with the fracture and she lay in bed for two months. She then got up, but complained that walking was painful and was put back to bed. As she persisted in her complaints she was transferred to the infirmary, where she lay for over seven years. She was the picture of health, and her only disability was that the big toe lay transversely under the ball of the foot. Treatment was refused, because she did not wish to leave the institution in which she had been treated so kindly.

Steps have now been taken to supply simple "cradles" to all the beds.

Hemiplegia

The common consequence of a vascular lesion involving the internal capsule is familiar: spastic paralysis in extension of the leg on the opposite side; adduction of the arm at the shoulder, flexion of the elbow, and sometimes extreme flexion of the wrist and fingers with rotation of the forearm. In a few the flexion of the fingers is sufficient to cause the nails to make deep grooves in the palms of the hands. We were surprised to find in a number of patients some years after the original stroke that the posture of the limbs varied from the usual pattern. In some there was gross flexion of the affected leg with the knee drawn up to the belly, and the arm might be either extended or flexed at the elbow. At first we thought that the variation was the result of another stroke, but we could obtain no history suggestive of an episode of that kind: several experienced nurses assured us that the postural pattern of the affected side of the body slowly and almost imperceptibly changed in the course of years, and some considered that the flexion deformity of the leg could be prevented by massage, movement, and daily traction. We examined a number of these anomalous cases in great detail; there were no demonstrable sensory changes, and the departure from the usual pattern could not be related either to spontaneous activity after the stroke or to any form of physical treatment or position in which the patient had been nursed. It is of course conceivable that these irregular postures developed as a result either of slowly progressive thrombosis around the original lesion or of independent vascular occlusions in other situations which we failed to trace. If the observations of the nurses about the slow insidious course of the change in posture are correct (and I have no reason to doubt them) there is an

obvious need for careful study of the morbid nervous anatomy of these cases.

We noticed, too, in a few cases some difference between the texture of the skin on the paralysed and unaffected legs, and we propose to investigate this by biopsy to see whether inactivity of a limb leads to demonstrable structural change in the skin.

Incontinence of Urine

Incontinence in the aged and chronic sick is the most serious of all the problems in the day-by-day management of an infirmary. The burden that it places on the nursing staff needs no emphasis. I remind you only that no fewer than 457 were always or occasionally incontinent out of a total of 943 bedridden patients when we began our survey. The cost in laundry and in the wear and tear of bed linen is formidable. Preliminary analysis shows that a large proportion developed incontinence after admission to the institution and confinement to bed for varying periods. Of the 714 patients included in the survey 252 were incontinent—79 males (25%), 173 females (44%). The proportion is smaller than the one given to us on our first visit because our figures exclude some of the occasional and accidental offenders. Of the 252 cases 97 were certainly incontinent on admission, but no fewer than 108 lost control of the bladder while in the infirmary; in 47 cases the date of the onset was unknown.

In only one-quarter of all the incontinent cases was it possible to find a physical condition that might reasonably be considered to be the cause of it, but no investigation worthy of the name has been possible. An important result of our analysis of this symptom was the fact that in these patients incontinence in either sex was not a consequence of age; there was very little difference in the incidence in the ten-year groups 60 to 69, 70 to 79, and over 80.

In the Leeds survey the proportion of incontinent patients was much smaller (males 8.5%, females 10.5%). I have already suggested that the better condition of Affleck's cases may have been due to greater activity in the wards.

There was general agreement that incontinence could not be avoided by "screening" rounds even at very short intervals; patients might be left with bed-pans for ten minutes without result and the beds would be soiled within a few minutes of their removal. We tried the effect of acetylcholine derivatives to produce a result while the bed-pan was in position, but the experiment failed and the patients resented the injections. It had been noticed that if bedridden patients were encouraged to get up and move about with help from the nurses the incontinence often ceased, but the labour of getting them out of bed and caring for them when up was greater than that of cleaning them every four hours and was too much for the small staff.

The reverse was also true: a few clean bedridden patients became incontinent when they were removed from bed—especially if the adventure was undertaken against their wishes—and it was clear that evacuation of the bladder and bowel was with several of them a sort of protest against the disturbance of their peace.

These facts suggest that much incontinence in infirmaries is due to psychological disorder induced to some extent by institutional routine, although it may also be aggravated by infection and local pathological changes. The patients do not seem at all distressed by it, and this supports the view that the mental factor (the lack of conscious inhibition) is more important than the overactivity of the bladder mechanism that Wilson (1948) found by cystometric methods.

Psychologists have expressed the opinion that incontinence in the senile is a form of regression to the anoral eroticism of infancy. It may be so. I lack the training and ability to explore the unconscious motivation of the incontinent who were brought to my notice. The analysis must, I think, be difficult.

Of one thing I feel confident—that the burden of incontinence will not be reduced until it is possible to ensure greater activity and more effective treatment to the senile and chronic sick than is now possible with the restricted staffs of the infirmaries.

The Clinical Material

The patients of a large infirmary are a rich mine of clinical material for teaching and investigation. Strange phenomena of human pathology abound, and one of my registrars, after a happy afternoon with cases of hereditary cerebellar ataxia, Huntington's chorea, and paraplegia due to localized Paget's disease of the spine, remarked that the place was a censor's paradise. The simile is fair, but lacks precision; his recent struggle for the membership of this College had perhaps clouded his judgment of the appropriate paradise for censors.

Our original intention was a clinical classification of the patients based on accurate diagnosis, but, apart from the inherent difficulty of the extent and variety of the material, we were confronted with so many individuals who showed evidence of numerous distinct and serious pathological processes in one body at one time that we found it impossible to classify them even by "systems." This was true in at least half the cases, and in the remainder a single diagnosis was often not more than approximately accurate because in achieving it the psychological condition, the blood pressure, and the state of the arteries might be conveniently ignored. We eventually decided to classify the patients according to the condition which seemed most disabling at the time of survey. Thus, in Table V, "cardiac conditions" include only cases of gross cardiac failure and not those with symptoms of cardiac insufficiency. Chronic bronchitis with heart failure was classed as cardiac; advanced arthritic changes with hemiplegia were counted as arthritis, and severe hemiplegia with moderate arthritis was reckoned as cerebral thrombosis, and so on. In the senile groups were the extraordinary contractures that have already been described. The final result, for the reasons that I have given, is of dubious value. The large numbers of cases with multiple pathology led me to heretical criticism of the theory of the single diagnosis.

TABLE V.—*Diagnostic Category of Most Disabling Condition at Time of Survey*

Chief Disability	Males				Females			
	No. of Cases	% of Total	Mean Age (Years)	Mean Stay (Months)	No. of Cases	% of Total	Mean Age (Years)	Mean Stay (Months)
Cerebral thrombosis	73	23	72	23	61	16	73	37
Senility	43	14	79	47	67	17	83	39
Cardiac conditions	29	9	73	23	46	12	77	33
Chronic bronchitis	27	8	76	28	33	8	75	42
Arthritis	20	6	74	44	53	13	75	45
Result of fractures	16	5	75	44	16	4	78	27
Nervous disease	15	5	60	70	5	1	61	44
Dementia	14	4	76	17	33	8	82	31
Cancer	13	4	73	7	12	3	73	10
Parkinsonism	12	4	62	47	13	3	64	50
Tuberculosis	3	1	66	28	2	1	51	8

Other diagnosis	21	7	72	39	41	10	72	45
No diagnosis	21	7	74	31	14	4	67	23
Total	318	100	74	34	396	100	76	37

The Theory of the Single Diagnosis

This dogma of the single diagnosis holds almost undisputed sway in English medical teaching. It is founded on the simple faith that if we are clever enough and thorough in our investigation of a clinical case we will eventually be able to show that all the symptoms and all the physical signs are the result of a single process of disease. The appropriate label may then be affixed, honour is satisfied, and the dogmatic are content. I do not think I exaggerate. On all sides I hear the warning, "Don't diagnose two diseases simultaneously." Those about to give classes search diligently for good teaching material, by which they mean cases which permit the plausible demonstration of the validity of the theory: clinical examinations are conducted to test (among other things) ability in this exercise.

I can find no specific account of the origin of the theory: I suspect that, like Topsy, "it just growed" in the nineteenth century under the stimulus of the triumphs of exact science and with the development of morbid anatomy, the discovery of micro-organisms and the consequences of their invasion, and particularly, perhaps, with the elucidation of certain obscure syndromes and their constant association with gross lesions in particular organs. Consider, for instance, Addison's disease of the suprarenals—its strange and perplexing symptoms and signs and the splendid demonstration that they were hardly ever found in a patient without manifest destruction of one or both of two small glands.

The discovery of the bacillus of tuberculosis, the definition of the architecture of the basic lesion, and its natural history showed that many very dissimilar clinical conditions were in truth the result of a single pathological process. Before this advance had been made it was difficult to believe that there could be a unity linking chronic phthisis in the adult with tuberculous meningitis in the infant, although a few physicians with prophetic insight had suspected it. The proof that the pale spirochaete was the cause of all the varied lesions of syphilis and especially of general paralysis and tabes, had a like influence, and it is unnecessary to multiply examples.

The human mind longs for order, and soon the theory of the single diagnosis was born and waxed mighty. And indeed it served a very useful purpose, for adherence to it undoubtedly led to more careful examination and more accurate classification of clinical syndromes. Pragmatically the theory was justified; it worked. Later it was buttressed—as useful theories are often buttressed—by somewhat dubious argument. A hypothesis of independence was introduced (I do not know whence) which stated simply that, as in human beings serious disease apart from epidemics was a rare event, it was inherently improbable that two serious processes of disease would coexist in the same person. But this argument neglects important facts.

First, a person who is already the victim of one serious disease is often as a direct result more prone to develop another. Consider, for example, the high incidence of cancer in the post-cricoid region in patients who have suffered long from an iron-deficiency anaemia, or the frequency of arterial degeneration in the diabetic. Textbooks recognize the coexistence of serious diseases, but in deference to the theory of the single diagnosis they call one of them a complication of the other.

Secondly, a disease which in a healthy man is but a trivial affair may in those already subject to a serious malady assume lethal significance. A sore throat in a strong young man is unpleasant; in the victim of chronic nephritis it is something worse.

Thirdly, the longer a man lives the more likely is he to bear scars and disabilities of previous indiscretions and random attacks of disease which may in part be balanced by the acquisition of "immunological wisdom" by his tissues. The response to fresh disease or injury in the sick and aged will therefore paint a clinical picture confused and complicated by differing contributions from many sources, and the assessment of the relative importance of the separate contributions is the particular task of the clinician rather than the construction of a single diagnosis to account for them all.

As I have already said, the application of the theory of single diagnosis, which has given the familiar working world of doctors the fallacious appearance of a multitude of separate and unrelated disease processes, has produced results of the greatest practical value—not only in the recognition of disease and the discovery of effective treatment of its immediate cause, but also by the accumulation of knowledge which enables us to prevent or restrict the operation of those causes. At a certain stage in the training of students, too, dogmatic teaching has its worth. The theory is therefore not lightly to be set aside as a working hypothesis; in acute illness occurring in the young or previously healthy a single diagnosis is likely to be justified, but in the aged and chronic sick it is rarely relevant

The Problem of Ageing

Senescence implies a series of changes most of which commonly but not invariably occur in an individual who has lived through a period of chronological time. In man the changes are familiar: the skin is pale, often yellowish, wrinkled, and inelastic. On the backs of the hands purpura is common and there is patchy pigmentation of brownish hue. The hair is white and often sparse, the back is bowed, the limbs are sometimes tremulous, and the teeth are lost. Movement is slow and often clumsy. There is a tendency to fall, and, as Sheldon has shown, the fears of accident may be so great that they dominate the life of the old person. Muscular effort entails distress, especially with breathing. Sleep is short and easily disturbed, though drowsiness is frequent. Vision fails and deafness is common. Sexual desire wanes and infertility in females is absolute and in males possible.

Observation of others and, more rarely, contemplation of ourselves acquaints us with certain more subtle changes in personality—the conservatism and intolerance of change, a slightly contemptuous indifference to popular opinion and fashion, the loss of memory for recent events, and the difficulty in recalling names. All these things, with the physical changes, are accepted as natural, inevitable, and irreversible with the grim resignation that proclaims that an old dog can't learn new tricks.

It is reasonably certain that ability to learn declines in the human species soon after growth ceases, but my colleague, Professor M. V. C. Jeffreys, of the Department of Education, tells me that no work has been done in this country that justifies any opinion about that quality in those over 50 years of age. In America preliminary investigation suggests that considerable capacity to acquire new knowledge and skill may be retained until late in life, and that judgment and experience may compensate in large measure for the slowness of the learning—an opinion that I can describe as comforting.

Foulds and Raven (1948), on the other hand, were satisfied that the capacity to form comparisons and to reason

by analogy diminished slowly after the age of 25. They did not investigate persons over 60 years of age, but said that if the rate of decline in later life remained the same as in maturity it would follow that by the age of 80 the average individual's ability to grasp fresh ideas and adopt new methods would be no greater than that of a child of 8. Eysenck (1945) had already produced evidence in support of that grim conclusion. Freud, too, at one time discouraged psychological analysis in patients above 50 "because old people are no longer educable." We may readily concede that mature experience is likely to prove an infertile soil for the cultivation of psycho-analytical concepts and reserve a hope that, for that reason alone, it may not be incapable of wisdom and greater knowledge.

With respect to the physical changes, belief that the disabilities of age are the result of a natural and inherent process in human life is based on the frequency with which they occur and the simple fact that no man has yet escaped death. The belief is also sustained by the common observation that longevity is often a familial characteristic and by the experimental evidence that modification or removal of one gene in Drosophila will materially affect the life duration of the resulting stock.

For several reasons, however, it is possible to maintain speculative doubt whether the changes of senescence are wholly inherent and inevitable in the course of life.

First, there is considerable variability in the time of onset of the disabilities of age not only in individuals of the same family but also in different peoples. Senescence occurs earlier, for instance, in tropical races than in those of the temperate zones. This suggests (but does not prove) that the effects of external environment, the incidence of infection, accident, malnutrition, or indiscreet excess may play a larger part in the development of senescence than has previously been suspected.

Second is the fact that in certain forms of life ageing does not occur. Insects die almost invariably without showing any signs of the wear and tear accepted as the usual prelude to natural death in the human being; a possible exception is the worker bee—the indomitable woman of the hive who is said to show a loss of hair and some fragmentation of the wings before she dies—but this is not certain.

Third is the strange irregularity of the distribution of changes attributed to age—the tissues of the body are not affected equally. In the vertebrates, including man, as Carrel has pointed out, these changes occur first in what may be termed the closed systems and the plasma, in the teeth, in the joints (arthritis deformans) and particularly the vertebral articulations, in the amount and distribution of fat, and in the arteries long before there is any detectable alteration in the organs. Are we to assume that tissues age independently of each other, or is it possible that these early changes in the closed systems are the result of metabolic or other disturbances conditioned from without?

Fourth is the riddle of marine life. Bidder (1925, 1932) has maintained that in natural conditions the growth of fish is unlimited by time and that they do not become senescent or infertile. They die by random chance, or "parental" deaths occur, as in the male salmon. Established knowledge is small and the matter highly debatable.

These mysteries have more than intellectual interest; in view of the changing age structure of human populations they are among the most urgent of our problems. In the present state of knowledge, it seems to me, senescence must be regarded as the product of two components or groups of factors: (1) effects produced in an individual by processes inseparable from life as an organism over a period of time; and (2) random effects of changes in environment, disease, famine, surfeit, and activity. Age and death are phenomena resulting from the variable interaction of the two.

Influence of External Conditions on Ageing

There is no satisfactory definition of ageing. Minot (1908) measured vitality in terms of growth; not the mere rate of growth but the specific rate—that is, the ability of living tissue to reproduce itself at the same speed as that at which it was itself formed. If that criterion be accepted the vitality of tissues declines soon after the fertilization of the ovum; at first reproduction is unrestricted in geometrical progression—from the zygote to 2, 4, 8, 16 cells—but as not more than between 300 and 400 cellular reproductions are likely in the whole nine months of gestation the rate must soon decline. In other words, man has aged considerably before he is born, and continues to age rapidly in youth and more slowly as life advances.

In a study of the shape of the human form as a function of time my colleague, Professor P. B. Medawar (1943), reached a parallel conclusion—that the rate of change falls off progressively from the fifth month of foetal life to maturity. In a review (Medawar, 1942) of the biological mechanisms controlling growth he recorded the opinion that it is likely that there is a non-diffusible protein in the intercellular fluids of adults that discourages the inception of free growth.

Minot's ideas raised the problem whether changes in the rate of growth might alter the vitality and survival of organisms. Early experiments in mice led to the belief that a high rate of growth was associated with increased longevity, but the result was dubious because the possible influence of genetic differences had been ignored. Study of the brook trout, indeed, suggested that the relation of rates of growth to longevity might be inverse, and Saxton (1945) investigated the matter afresh in rats carefully selected to avoid genetic difference. He found that, if the rate of growth were reduced by feeding them on a diet properly balanced in respect of all the known essentials but of smaller calorie value than the rats would normally consume, the longevity of the experimental animals was increased by no less than 100% when compared with that of a similar group on unrestricted diets. This remarkable increase was noted in both specific and potential longevity, in the mean age of survival of the group, and in the duration of the life of the individuals.

The application of such diets to rats at maturity undoubtedly prolonged their lives, and this experimental result strengthens the appeal for moderation that the empirical wisdom of physicians has so often addressed to the middle-aged.

That I should not be charged with the wish to impose moderate hunger as a condition of the discipline of well-conducted nurseries I think it prudent to say that in my judgment Saxton's general conclusion, that retardation of growth in rats by restriction of calories significantly increased their life span and reduced the development of inflammatory, neoplastic, and degenerative diseases, is of only theoretical interest until we learn the fate of successive generations of animals bred in such conditions. His work is none the less important, because it shows that longevity in rats may be increased to a surprising degree by a simple change in diet.

The Evidence from Botany

There is great variation in the life span and life cycle of different plants, and both the span and the cycle may be greatly modified by artificial culture. Monocarpic plants mature seeds but once and die. Why they die is unknown: it may be from starvation due to exhaustion of available food by seed production or the result of some poison

elaborated in the process. Nevertheless the life of monocarpic plants may be indefinitely prolonged by modifying their environment in such a way that growth continues without the formation of flowers and seeds.

Gardeners long believed that vegetative reproduction soon led to degeneration and that sexual propagation was in some way necessary to rejuvenation. But it now seems probable that the degeneration was in fact due to virus diseases, which only exceptionally are transmitted through seeds. In perennial plants there is no certain morphological evidence of senescence in succeeding years, though the temporary organs such as leaves and fruits show obvious cycles ending in senescence and death. The conclusion is that suitable modifications of external conditions may enormously prolong the period of growth and survival of plants and seeds.

Tissue Culture

There is now no doubt that the life and reproduction of most cells may be prolonged by artificial culture beyond the limit of the natural span of the organism from which they are taken, although some of them, like those of the nervous system and the muscles, soon become incapable of reproduction. It has been noticed, too, that cultures from an aged tissue, though slow in starting, will grow as well as those from a young one and that the growth is favoured by the introduction of tissue fluids from a young animal of the same species. The interesting problem arises whether the ageing of tissues may be a consequence of some humoral change in the organism.

These fundamental questions in the present state of knowledge have little immediate relevance to the urgent problem of the infirmaries, but I mention them to show that the study of the aged and their disabilities may be something more than an exercise in clinical taxonomy and worthy of the attention of physicians.

Our work in Birmingham is in a preliminary stage; we have found in apparently healthy old men a curious alteration in the pattern of the chemistry of the blood—the sodium and the chloride are reduced, there is delayed response to hypoglycaemia due to intravenous insulin, the storage of vitamin C is defective, and there is a diminished excretion of 17-ketosteroids. These changes suggest a deficiency in the adrenal cortex, but there is no increase in the blood potassium or any clinical evidence of Addison's disease. Injections of testosterone restore the pattern of the blood chemistry to the accepted normal and the patients gain several pounds in weight and profess that they feel better. Clinical physicians have exceptional opportunities in this field, for to them alone will come the cases of sudden and premature senescence which may be expected to afford material suitable for exact investigation. All of us are familiar with the rapid ageing of healthy individuals submitted to the strain of injury, bereavement, fatigue, and illness, but the biological processes underlying the manifest change are rarely studied—the condition is accepted as "natural." And yet in these cases the phenomena of age are sometimes reversible. In this connexion I cite a published case (Thomson, 1938) illustrating the sudden appearance of senility after an accident.

> In April, 1937, a healthy virile man aged 55 had his hand crushed in a machine and suffered much pain. In three months he was completely bald and withered; his weight fell from 10 to 8¼ st. (63.5 to 54 kg.) and his friends did not recognize him. Sexual desire almost disappeared, and he shaved only once a week instead of daily. His hair slowly grew again and was white; his skin was wrinkled and inelastic. There was no change in the external genitalia, but the pubic hair was scanty. No evidence of disease was found after investigation in the out-patient department, and he refused admission. I saw him at intervals for several months and he improved slowly without treatment. Two years later his hair was brown and thick, he regained his normal weight and lost all trace of senility; sexual desire had returned, and he had to shave every day.

Similar changes are to be observed in women who suffer ischaemic necrosis of the pituitary as a consequence of severe haemorrhage or infection at parturition, and I have twice seen the sudden development of senile changes in cases of the so-called Lorain infantilism. For more than twenty years I have had under observation a dwarf, now 36 years old, who suffers from epilepsy but has no other symptoms or evidence of illness. Recently he has shown signs of sudden ageing, mainly in the wrinkling and loss of elasticity of the skin. Soon, I believe, as happened in the other two cases, he will be a typical example of the progeria of Hastings Gilford.

Summary and Conclusion

The Clinical Aspect

My purpose when I set out on this inquiry was simply the discharge of what seemed a disagreeable duty—the discovery of the best means of improving the state of the institutions for the aged and chronic sick in the Birmingham region. I now believe that the problem is one which intimately concerns the whole of clinical medicine and yet has been almost entirely neglected.

To restore the study of the aged and the chronic sick to the common stream of medical activity seems to me the paramount necessity, and the first step must be the establishment of wards in general hospitals and particularly in teaching hospitals for this purpose. Some assert that it is necessary to develop yet another specialty in the shape of geriatrics. I do not share that opinion. The problems of the aged and infirm are so varied that narrow specialism is unlikely to be profitable. Medicine to-day is too fissiparous; it breeds too many specialties. It is my view that this field is properly the domain of that under-privileged class the general physicians, and that by cultivating it they may contribute to the integration and generality of knowledge for which the Harveian Orator pleaded lately and so eloquently.

The virtual exclusion of the aged and the chronic sick from the wards of teaching hospitals is responsible for serious defects in the training of medical students. In general practice the care of such patients constitutes a considerable proportion of the work, and the fact that the newly qualified embark on it relatively untrained is a reproach to clinical teaching. In excuse it is urged that the pressure of the waiting-lists has prohibited the admission of these patients, and in the past that has been true. The difficulty is not insoluble.

In the Birmingham Region we estimate that the waiting-list of general medical and surgical cases is about 14,000. Of these, 60% are cases of hernia, piles, varicose veins, and prolapse. My belief is that the provision of a few recovery hospitals to which clean surgical cases of this sort could be removed within a few days of operation would end the problem of the waiting-list and permit the establishment not only of wards reserved for the aged and chronic sick but also of provision for specialized services.

In the wards for the aged in general hospitals the duration of stay should rarely exceed three months. Our analysis has shown that the critical period in which the fate of the elderly is determined is about 100 days—that is, whether they die or become fixed in an infirmary bed for years or return home. In a general hospital that period would not only enable a proper decision to be taken about the best provision for the individual but it would permit

research and dispose of the scandal of admission to the infirmaries without adequate investigation—the position at present in six out of seven admissions to the Western Road institution. In Hereford County Hospital and in the Manor Hospital at Walsall in Staffordshire we found in the course of our survey wards reserved for the reception of all patients above the age of 65 irrespective of the cause that led to their admission, and we had no doubt that the treatment and disposal of the chronic sick was better done as the result of it. Finally, there is no doubt that a necessary prelude to real improvement in the chronic institutions is regular visiting for teaching, investigation, and review by physicians in active charge of general hospital beds.

Social Aspect

A summary of our pilot survey justifies the following conclusions:

1. The outstanding characteristic of the patients is advanced age, but the mean age of the patients in the infirmary is less than that in the Highbury Home for old people, where the inmates live actively and pleasantly and at less cost to the community.

2. Of the bedridden patients in Western Road Infirmary, who form the overwhelming majority, in only a minute fraction (5%) is there any hope of rehabilitation. Disintegration of personality in the apathy of institutional routine, the development of incontinence, the contractures and deformities produced by long inactivity in bed, the lack of adequate treatment by physical methods, and the dissolution of homes are to a great extent responsible for this disaster.

3. Reform should be directed towards the prevention of complete disability in the senile. In the strictly realistic order of their possible achievement I suggest the following:

(*a*) The restoration of the care of the aged and chronic sick to the common stream of medical activity in the way that has already been described. Thomson and Curran (1948) have shown that the treatment of the old in general hospitals often leads to speedy recovery.

(*b*) Measures to maintain the cohesion of the homes of the elderly: the provision of medical and social services from the hospital as at Carshalton, the encouragement of a sense of family responsibility by training a member of it in the care of the invalid and perhaps by payment for the work done, and occasional admission of the invalid to an institution to allow holidays to those normally in charge.

(*c*) The provision of hostels, special housing, or accommodation for the aged in which central services and some form of domestic help is available. There is no need for uniformity or central control in this direction: local conditions and individual circumstances are infinitely varied. In an analysis of a sample of applications for help directed to the Welfare Department of the Birmingham Council for old people Miss J. E. McCrindell found that the vast majority came from independent old people who found that the battle of life was becoming too much for them and needed help at home. The sample was composed as follows: women 79% (widows 52%, spinsters 27%), men 16% (widowers or bachelors), and married couples 5%. Many of these will be on the waiting-lists of infirmaries unless some help is given soon.

(*d*) Industry should be encouraged to examine the conditions of the elderly in employment to discover whether adjustment is possible to prolong the useful working life of individuals beyond the customary age of retirement. A remarkable example of initiative in this direction is a special shop at Lucas's factory in Birmingham, which I was privileged to see. In this department were collected about 50 men and women, most of whom had given several years' service to the firm and then failed to keep pace with the rate of production of their fellows. In the majority the reason for the failure was premature senescence, but occasionally there was a specific physical disability. Instead of discharging them the firm established this department where they did light work in special conditions. When I ventured to say that the enterprise seemed to be an admirable example of enlightened altruism I was promptly told not to confuse sensibility with sense: the shop had been costed and it paid.

The Problem in Relation to Evolution

It has been somewhat slickly said that what happens to individuals beyond the age of reproduction is of small importance to the race; that their fate is simply not on the agenda of evolution. It is conceivable that senescence and death soon after the term of fertility may have been genetically determined in the long struggle for survival, because in primitive conditions a race composed of the young and vigorous would undoubtedly triumph over another with a large contingent of the elderly. But human evolution is no longer determined solely by a struggle with the natural forces of the environment or by combat decided by mere physical fitness. The unique quality of mind and the development of a literary tradition are new and potent factors in directing human progress, and it may be that the wisdom of the old, less perturbed by sexual and other passion, has a greater part to play than is commonly believed. Twenty-five years have passed since George Bernard Shaw first propounded the gospel of the Brothers Barnabas in the second part of his metabiological pentateuch, *Back to Methuselah*. The brothers had become convinced that the confusion of civilization in Western Europe was due mainly to the childishness of statesmen, and that final catastrophe could not be avoided unless the span of human life were prolonged so that government might be entrusted to individuals with 200 years of training and experience instead of immature striplings in the sixties. We may justly be dubious of the biological mechanisms postulated by the Barnabas brothers and yet retain some sympathy with their doctrine that wisdom and experience in high places have some advantage over the brightness of puerility. That idea has helped me in this contribution to the study of the problems of the aged.

The Management Committee of the Western Road Infirmary made this inquiry possible, and I am particularly indebted to the Chairman of the Hospital Group, Mr. Vernon Grosvenor. Dr. Charmian Elkes, Dr. S. E. Hallisey, and Dr. P. M. Meynell did the exhausting work for the statistical survey with the help of two trained social workers, Miss Honor Pringle and Mrs. Leaver. My three registrars, Graham Marson, Lewis Arundell, and J. M. Winn, were of great help. Dr. L. Nagley, the medical superintendent, and Miss M. Thomas, the matron, of the Infirmary put their wide experience and great knowledge generously at my disposal.

THE RETURN TO WORK OF ELDERLY MALE HOSPITAL IN-PATIENTS

BY

JOHN PEMBERTON, M.D., M.R.C.P.

AND

JOAN C. SMITH, B.Sc.Econ., A.M.I.A.

(From the Department of Medicine, University of Sheffield)

The following study was undertaken to find out to what extent male patients aged 50–64 admitted to the general medical and surgical wards of a teaching hospital were subsequently able to return to work. Three groups were selected for study:

(A) All those admitted to medical firm A's beds between Nov. 1, 1946, and Oct. 31, 1947. 102 patients.

(B) All those admitted to medical firm B's beds between Jan. 1, 1947, and Feb. 16, 1948. 100 patients.

(C) All those admitted to the wards of a general surgeon between Oct. 1, 1946, and Feb. 10, 1947, and between June 1 and Nov. 1, 1947. 100 patients.

Method

The aim was to follow up 100 patients in each of the three groups. A date was chosen which would give an average follow-up interval of six months after discharge from hospital. No case was followed up sooner than three months or later than eighteen months after discharge. The names of patients were taken seriatim from the hospital admission list until the number required had been obtained. A circular letter was sent to each patient asking if and when he had returned to work and whether he had gone back to his old job or to a new one. He was invited to call at the hospital if he required any further help from the social service department. Patients who failed to answer or to provide the information required were visited by the almoner. Half the patients replied satisfactorily to the inquiry, about one-third were visited at home, and the remainder came up to see the almoner at hospital. Those who had died either in hospital or after discharge were included in the study to provide a complete picture.

The age distribution of the three groups is shown in Table I. About one-third of each group fell in each quinquennium. The fate of the patients in the three groups after admission to hospital is shown in Table II.

TABLE I.—*Age Distribution of the Three Groups*

Group	50–54	55-59	60–64	Total
A. Medical	38	35	29	102
B. Medical	32	32	36	100
C. Surgical	36	36	28	100
All groups	106	103	93	302

TABLE II.—*The Fate of the Patients*

Group	Total Admitted	Died in Hospital or Between Discharge from Hospital and Follow-up	Not Back at Work	Returned to Light Work	Returned to Old or Similar Work	Untraced
A. Medical	102	47	14	8	29	4
B. Medical ..	100	30	16	9	38	7

The Medical Cases

Of the medical cases, 38.1% died in hospital or after discharge, 14.9% did not recover sufficiently to resume work, 8.4% were able to return to "light" work, 33.1% resumed their previous employment, and 5.5% were untraced. The results were less good in group A mainly because this group contained more cases of coronary disease (13) than group B (6) and fewer cases of peptic ulcer (8 compared with 23).

Return to Work in Relation to Diagnosis.—There was naturally a close relation between the patient's ability to return to work and the nature of the illness from which he suffered. Table III shows the numbers returning to work

TABLE III.—*Diagnosis and Fate of the 202 Medical In-patients Aged 50–64*

Diagnosis	No.	Died in Hospital or After Discharge	Not Returned to Work	Returned to Light Work	Returned to Old or Similar Job	Untraced
Pulmonary infections (excluding tuberculosis) ..	44	11	6	3	22	2

in the different diagnostic categories in groups A and B. Half the 44 cases of pulmonary infections (excluding tuberculosis), 19 of the 31 cases of peptic ulcer, three of the 19 cases of coronary disease, two of the 10 cases of nephritis, and one of the 14 cases of essential hypertension were able to return to their old jobs. None of the 23 cases of cancer or the four cases of cerebrovascular disease got back to full work, although one cancer patient returned to light work.

Failure to Return to Work.—Of the 30 patients who did not return to work, one was fit for work but was unable to find suitable employment. The other 29 patients were medically unfit. Of these 29, one had been transferred to the local infirmary, one to a mental hospital, and one was awaiting admission to a sanatorium. Six patients had given up work because of their illness before the exacerbation which led to their admission to hospital.

The most important reason why these 29 patients failed to return to work was that the illnesses from which they suffered were chronic or progressive and their course could not in most cases be reversed or arrested by admission to hospital. As Brown and Carling (1945), in a more general study of the social aspects of hospital medical cases, wrote: "For the majority of the patients the stay in hospital was merely an episode, sometimes a relatively brief episode, in a protracted period of disability and treatment." A secondary reason why some patients failed to return to work was that their usual occupation was too strenuous for all but the physically fit.

The three chief industries in Sheffield and its neighbourhood are steel-making, coal-mining, and the manufacture

of edged tools and cutlery. Much of the work in these industries is arduous and involves considerable muscular effort and exposure to various dusts or great variations in temperature. Furnacemen, foundry workers, metal-grinders, and coal-miners experience mortality rates for bronchitis and pneumonia considerably in excess of that for the general population (Registrar-General, 1938). It is not easy for the elderly Sheffield workman who has been employed in the steel or coal-mining industry and who has been partially disabled by a serious medical illness to find suitable alternative work.

Return to Light Work.—Seventeen of the medical patients were able to return to less arduous work than their usual occupation. The diagnosis, previous work, and "light" work obtained in this group are shown in Table IV. It was in

TABLE IV.—*The 17 Medical Patients who Obtained Less Arduous Work*

Age	Diagnosis	Previous Work	Light Work
51	Fibroid, pul. tub., and silicosis	Furnaceman	Light labouring work at old firm
58	Duodenal ulcer	Handling sheet steel on heavy press	Light labouring work at old firm
55	Pneumonia and bronchiectasis	Furnaceman	Painting at old firm
54	Osteoarthritis and emphysema	Steel tester in coal mine	Registered as disabled person. Obtained light work at colliery surface
51	Coronary thrombosis	Government inspector. Much travelling	Sedentary clerical work
64	Arteriosclerosis	Labourer at furnace	Sweeper-up at old firm
51	Diabetes mellitus	Insurance agent. Became unemployed because of illness	New clerical job
54	Essential hypertension	Silver-spinner	Light turner at old firm, sitting down; 9 a.m.-4 p.m., 5-day week
51	Bronchitis and emphysema	Coal-face worker	Surface job at former colliery
59	Duodenal ulcer and pulmonary tuberculosis	Forgeman	Lighter job in timber yard at old firm
59	Essential hypertension	Tram driver	Watchman in tram shed
55	Coronary thrombosis	Insurance traveller	Works timekeeper
60	Bronchial carcinoma	Cutler	Same works, lighter job, 6-hour day
50	Coronary thrombosis	Gas worker	Light labourer, same works
50	Coronary thrombosis	Furnaceman	Light labourer, same works
51	Arteriosclerosis	City policeman	Given lighter duties
62	Essential hypertension	Silver hammerer	Old job, but only 6 hours a day

this group that the almoner was most often able to help the patient in his return to work. The following case histories are illustrative:

A furnaceman, aged 51. Fibroid tuberculosis and silicosis. Unable to do previous work because of breathlessness. Was registered as a disabled person at the Ministry of Labour, and the almoner approached his employer, who eventually found him light labouring work in the steel works.

A silver-spinner, aged 54. Essential hypertension. Could not return to his old job, at which he earned £8 10s. a week, as he was unable to stand for any length of time owing to dizziness and fatigue. He was registered as a disabled person, and the almoner wrote to his employers, who were very co-operative and allowed him to return as a light turner. He was able to sit down to this work, and worked from 9 a.m. to 4 p.m. for five days a week at a wage of £4.

An insurance agent, aged 51. Diabetes mellitus. He was unemployed when the follow-up letter was sent. He was then registered as a disabled person and found temporary clerical work. The disablement rehabilitation officer promised to fit him into a better position as soon as one became vacant, and he was later found permanent employment as a clerk in the Ministry of National Insurance.

Return to Full Work.—Sixty-seven of the 202 medical patients were able to return to their previous employment. It is, however, probable that some of these patients—for example, those who had been admitted to hospital for coronary disease, nephritis, or chronic respiratory disease, and who managed to return to their old jobs—would not be capable of the same occupational effort as before or remain much longer at work.

Bronchitis, Bronchiectasis, and the Pneumonias.—Non-tuberculous pulmonary infections constituted the commonest cause of morbidity in the medical group. The 44 cases under this heading included 15 diagnosed as pneumonia or lobar pneumonia, 13 of bronchitis and emphysema, eight of bronchiectasis, five of bronchopneumonia, two of lung abscess, and one of empyema. In a survey of illness in general practice (Pemberton, 1949) "bronchitis" was found to be the commonest complaint diagnosed by a group of Sheffield general practitioners. It accounted for 11% of the 4,814 diagnoses, and in men the frequency steadily increased through working life. The group of illnesses which includes *bronchitis, bronchiectasis, and the pneumonias constitute* an extremely important cause of morbidity and mortality in elderly men. The aetiology of these conditions is imperfectly understood and in consequence their prevention hardly attempted. There is, however, a high mortality from these conditions in certain occupations which are common in Sheffield, as has been mentioned above, and this may to some extent account for their predominance in the present series.

The Surgical Cases

Table II shows that 15 of the 100 surgical patients died in hospital or after discharge, 13 failed to get back to work, six obtained "light" work, and 59 went back to their previous employment. Seven were untraced. Table V shows the fate of the surgical cases in relation to diagnosis

TABLE V.—*Diagnosis and Fate of the 100 Male Surgical Patients Aged 50–64*

Diagnosis	All Cases	Died in Hospital or After Discharge	Not Returned to Work	Returned to Light Work	Returned to Old or Similar Job	Untraced
Hernia ..	33	1	2	1	26	3
Peptic ulcer ..	11	2	3	1	5	
Cancer ..	8	5			1	2
Abscesses ..	6			1	5	
Haemorrhoids ..	5		2		3

Miscellaneous ..	10	1	1	1	7	
Total ..	100	15	13	6	59	7

Return to Previous Employment.—The surgical patients who were able to return to their previous employment included 26 of the 33 cases operated on for hernia, five of the 11 cases of peptic ulcer, and one of the eight cases of malignant disease. The last-named was a patient with sarcoma of the mesentery who for a time returned to his work as an inspector in the R.S.P.C.A. The high proportion of men operated on for hernia who returned to their old work emphasizes the value of this operation for maintaining and often increasing working capacity. Two of the 15 deaths occurred from medical illnesses—one from pneumonia and one from bronchiectasis—and six of the 13 patients who failed to get back to work were prevented from doing so by illnesses which either were non-surgical or were non-surgical throughout most of their course.

These were two cases of pulmonary tuberculosis, two of peptic ulcer, and two of cardiovascular disease.

Age and Return to Previous Employment.—As might be expected, there was a falling off with advancing age in the proportion of patients returning to their previous employment. In the medical cases there was a sharp drop between the 50–54 and 55–59 age groups: in the surgical cases the drop did not occur until the 60–64 period.

Discussion

The figures which have been given indicate that the majority of these elderly male medical and surgical patients either became fit enough to return to their old jobs or died. There remained two intermediate groups: those who did not become fit enough to return to work (15% of the medical and 13% of the surgical cases), and those who, while not becoming fit enough to resume their old work, were able to undertake less arduous employment (8.5% of the medical and 6% of the surgical cases). In these latter cases the almoner was often able to help by communicating with the previous employer or the labour exchange or a different employer, and explaining the needs and capacity of the patient. It was an advantage if the patient was registered as a disabled person so that he could be included in the legal quota of disabled persons in the factory concerned.

It was difficult to obtain a suitable job for the partially disabled man under a different employer. Usually there was no suitable work or the employer did not want the responsibility of taking on an elderly unfit man. Moreover, the patient usually preferred to return to the occupational environment which he knew and where he was known. He had perhaps spent twenty or thirty years there and could therefore expect sympathetic consideration. Employers in the Sheffield industries have usually, in our experience, taken their disabled employees back and found them less exacting work, although in many cases, owing to the small proportion of light jobs in these industries, it might mean that a workman became almost a "passenger." Of the 17 medical and six surgical patients who obtained lighter work after their discharge from hospital, 18 were taken back by their previous employers.

Beck, Gardner, and Witts (1947), reviewing the social service required for an unselected series of male and female medical in-patients, found that 10% needed assistance in changing their employment and, as we have done, that registration under the Disabled Persons Act and the use of the disablement rehabilitation officer were of value in finding patients suitable employment.

Ministry of Labour Retraining and Rehabilitation Centres and Remploy factories may help to solve the problem of the partially disabled elderly man. This type of patient, however, is unlikely to learn a new craft easily, and his physical condition may seriously deteriorate even before retraining is complete. Industrial rehabilitation for elderly medical patients does not yet appear to have been much developed. Usually, however, it is not a question of only retraining muscles which have become weak and inapt from disuse or of re-creating the desire to work but of employing a man at a much lower level of occupational effort. For this, the Remploy factory seems to offer the best solution. Here, the disabled man can be employed on a permanent basis and the work arranged to suit his capacity.

It is to be hoped that employers of labour on a large scale, whether in State or privately owned industries, will extend still further arrangements for re-employing their elderly partially disabled employees. Such arrangements might include retraining schemes within an industry, "protected" workshops, shorter hours of work, slower rates of output, and the provision of part-time employment. There are sometimes departments in a factory which because of the nature of the work done could be largely manned by the elderly and less fit. The report on old people published by the Nuffield Foundation (1947) emphasized the value to industry in wartime of the skill and reliability of workmen retained after pensionable age in light but skilled work. We have seen, for example, two old men of 85 and 83 who had been employed at the same silversmiths in Sheffield all their working lives, engaged on repairing silver ware. It is of course not so easy to provide these conditions in heavy industry, where the rate of premature disablement is already high.

Summary and Conclusions

An unselected series of 202 medical and 100 surgical male in-patients aged 50–64 were followed up for an average of six months after discharge from hospital to see to what extent they were able to return to their previous employment.

Thirty-three per cent. of the medical and 59% of the surgical patients were found to have resumed their previous work. Ability to return to previous employment was most closely related to the type of illness and to a lesser extent to the work normally undertaken.

Eight per cent. of the medical and 6% of the surgical patients were able to return to light work.

The social service required to help elderly men who are partially disabled by chronic or progressive illness to find suitable work and the industrial problems involved are discussed.

Thirty-eight per cent. of the medical and 15% of the surgical patients had died in hospital or before the follow-up.

It is clearly worth while on humane grounds, and also because of the need to conserve the nation's labour force, to arrange suitable working conditions for men who are partially disabled by medical or surgical illness years before the normal end of their working lives. At the same time attention should be given to the probability that some of these disabling illnesses—amongst the cases of chronic respiratory disease, for example—might have been prevented if the patient's working conditions had been healthier from the start.

Our thanks are due to Professor C. H. Stuart-Harris, Dr. T. E Gumpert, and Mr. H. Blacow Yates for permission to investigate their cases, to Professor Stuart-Harris for helpful advice and criticism, and to Miss B. I. Richardson for assistance in the preparation of this paper.

The Minister of Health is considering proposals to extend the range of gases and fumes included in the list of "noxious and offensive gases" which are controlled by the provisions of the Alkali, etc., Works Regulations Act, 1906. A draft order has been prepared adding to the list volatile organic sulphur compounds, and fumes containing carbonaceous particles from black production works and fluorine. The order also adds black production works, fluorine works, and acid sludge works to the list of scheduled works liable for registration under the Act, and it extends the range of processes carried out in sulphuric acid works, bisulphite works, and cement production works the carrying out of which renders the works liable for registration under the Act. The draft order is being circulated to interested organizations with a request that any observations should be submitted to the Ministry before July 23, and a public inquiry will be held before the order is confirmed.

BRONCHO-PULMONARY SEGMENTS OF THE LUNG AND THEIR TERMINOLOGY

BY

J. HARDIE-NEIL, F.R.A.C.S., F.A.C.S.

AND

W. GILMOUR, M.D., F.R.A.C.P.

(From the Oto-laryngological and Pathological Departments, Auckland Hospital, New Zealand)

As there has been some controversy concerning the entity of the segments of the lung we will consider these before dealing with the terminology. The bronchial tree varies in each mammalian species, so we may, by referring to comparative anatomy, gain enlightenment concerning the significance of the various homologues found. The term "broncho-pulmonary segment" is applied to a branch of the stem of a lobe of a lung which has on it secondary branches with masses of lung tissues called secondary lobules. A broncho-pulmonary segment with its secondary lobules is surrounded by connective tissue derived from the visceral pleura, which sends further prolongations separating lobules and penetrating the lung tissue as interstitial connective tissue. The broncho-pulmonary segments form areas that are, in the words of Ewart (1889), who first described them, "kept in isolation as regards their air supply and form separate respiratory districts." From pathological data it is noted that infection in them may pass towards the periphery or pleura, but only gross pathology such as tuberculosis or malignancy can break through their boundaries to invade the neighbouring segments.

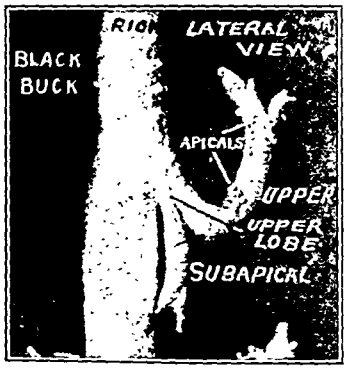

FIG. 1.—Lateral view of right upper lobe of cast of bronchial tree of black buck.

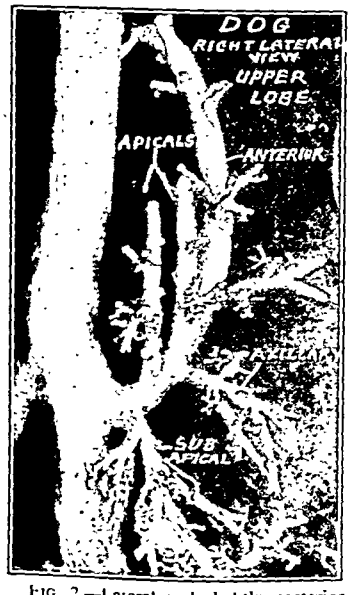

FIG. 2.—Lateral and slightly posterior view of cast of right upper lobe of bronchial tree of dog.

Willis (1676) was apparently acquainted with comparative anatomy when he drew the diagram of a lobar bronchus and its branches. It is corroborated by that of Huntington (1898) showing an embryonic mammalian lung. This type with many lobar branches is seen in some mammals, such as the pig and the wallaroo, but one of the earliest mammals or monotremes, the platypus, has an upper lobe closely resembling that of the human. In one of the herbivora, the black buck (Fig. 1), we find a simple type of the upper-lobe stem that divides into two trunks—the subapical below and an upper one. This division can be traced in all the mammals we have dissected. On the upper or cephalad aspect of the upper trunk of the black buck may be seen two obvious homologues of the apicals. In the dog (Fig. 2) two well-marked apicals come off this trunk. Intermediate between them, but on the lateral aspect, is a well-marked axillary branch that supplies an area between the anterior, or continuation of the upper trunk, and the subapical.

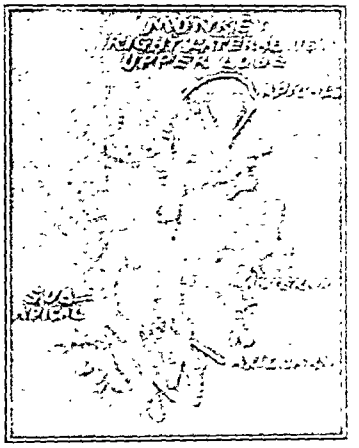

FIG. 3.—Pruned cast of right upper lobe of bronchial tree of monkey.

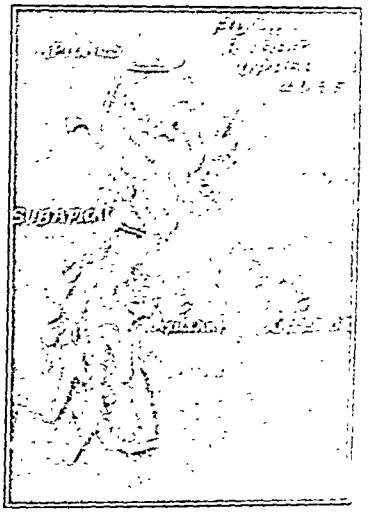

FIG. 4.—Anterior view of cast of right upper lobe of bronchial tree of human.

The Upper Lobe

If the apicals are granted segmental status a simple classification must be accorded to the axillary. In a monkey (Fig. 3) the two apicals are fused into one segmental bronchus. The axillary is well marked, whilst the remainder of the upper trunk, taking a ventral or an anterior direction, continues on as the anterior. We show a cast of the upper lobe of a human (Fig. 4), but it is only a confirmation of the diagram of Aeby (1880), which has never been challenged. In it there is practical coequality of the axillary and the anterior.

With progress in the gradation of the mammals the upper trunk shows, first, branches that fuse and serve the apical portion of the lobe. Then the axillary segment appears. After it is given off the upper trunk continues on as the anterior segment. Thus we see that, in accordance with adaptation, branches of a lobar bronchial stem, in conformity with the diagram of Willis, may disappear or fuse with another or may become aggrandized to form a separate segment. The axillary in the higher mammals becomes progressively enlarged and serves the area between the subapical dorsally and the anterior in front. The axillary is

readily accessible to bronchoscopy, can be filled separately with "lipiodol," and is a recognized site of lung abscess. On a lateral view of a radiograph it overlies the bifurcation of the trachea. The attempt to incorporate it with the anterior segment ignores anatomical and clinical accuracy and does not lead to clarification.

The Lower Lobe

In the lower lobe a controversy centres round the question whether the subapical has a separate entity or should be regarded as part of the posterior basal. Starting from the proximal end in the human there are given off in succession the apical, the cardiac on the right side, the anterior basal one or two, the axillary basal, and the posterior basal, which is the continuation of the lobar stem (Fig. 5). The relative

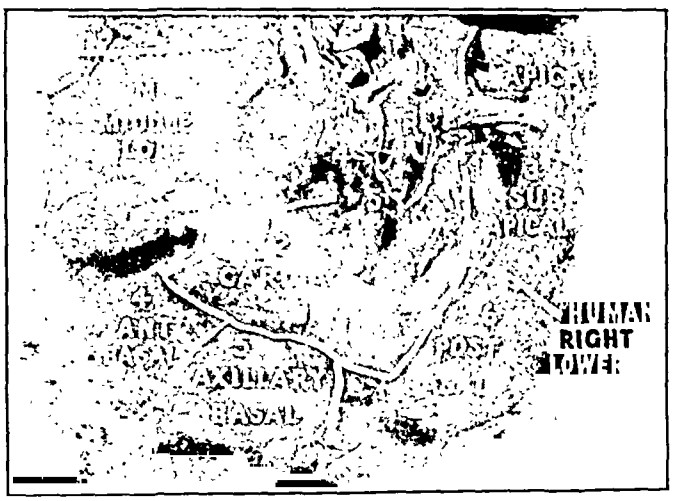

FIG. 5.—The human right lower lobe.

position of these is constant. In various positions from below the apical to above the final major division, where the axillary basal is given off, there may be found one to three segmental orifices distributed to the subapical segment which serve the lung between the apical above and the posterior basal below. Their distribution may be mediastinal, posterior, and lateral.

At times, particularly on the right side, the segmental orifice of a subapical may be as large as the apical segmental bronchus. It may be absent on the right side or on the left side, but it is present, however, as a substantial segment with an orifice often as large as the anterior basal in all the mammals we have dissected. Frequently on the left side in the human the proximal part of the subapical segmental bronchus is overlain by the apical above and the posterior basal below. Hence on inflation it has simply a lateral distribution.

Some contributors persist in showing the subapical of the lower lobe as part of the posterior basal—this in spite of the classical work of the first masters of bronchial anatomy, Aeby and Ewart, and the constant findings in the mammals that we have dissected. In his diagram, in which the bronchial tree is shaded to demonstrate his belief that it divides monopodially, Aeby shows the subapical definitely as a separate branch of the lower lobe of the bronchial stem, which latter eventually ends as the posterior basal. Consequently the last branch given off from the bronchial tree before it continues as the posterior basal is that of the axillary basal. A subapical branch must come off above this point to be classified as a broncho-pulmonary segment. Comparative and human anatomy definitely show this to be true. It is not possible to see how a subapical can be considered part of the posterior basal.

Preparation of Lungs for Inflation

We once more reiterate that the most satisfactory way of demonstrating the broncho-pulmonary segments is by the Moolten (1935) method of fixing the lungs. When the lungs are fully distended *in vacuo* the air sacs are fixed in that condition. On inflation the segments may be delineated just as in a map. If a lung is simply fixed in formalin the air sacs, in contraction, are filled with fluid and debris, and inflation may cause an artificial emphysema, masking the definite boundaries. We have given up using casts for the demonstration of the segments to students, as they are not easily recognized guides to the peripheral distribution. We have found it practically impossible to get any useful results from demonstration of fresh lungs in the necropsy room: they will develop artificial emphysema on inflation when apparently just fully expanded.

Moreover, when the bronchial stem in a fresh specimen is opened, the lung collapses in its full length and recognition of the various segmental orifices is very difficult to those not well experienced. Turning over a fresh lung and holding the collapsed slippery mass in an endeavour to demonstrate the segmental delineation by inflation is worth a trial by any investigator, as it will convince him of its uselessness for accurate delineation. The Moolten apparatus is cheap and easily constructed. Specimens prepared by this method will last for years without losing their segmental delineation. The method of preparation has already been described (Hardie-Neil and Gilmour, 1946).

Terminology

The terminology of the bronchial tree was discussed at the two meetings of the Oto-laryngological Section of the Pan-Pacific Surgical Congress in Honolulu in September, 1948. The consensus of opinion was that although the entity of the axillary segment of the upper lobe was definitely accepted its name could be replaced by the term "lateral" in conformity with modern anatomical terminology. Similarly the middle lobe main divisions could be termed "lateral" and "anterior." The name "apical of the lower lobe" is a convenient and localizing one in topography. Ewart described this segment as the bronchus dorsalis, but divides it into two branches—one the apical, and the other supplying the rest of the segment. As the term "dorsal" would apply to the apical, subapical, and posterior basal segments by position, it should be discarded. The term "apical" is more localizing, and anatomically corresponds with the apical of the upper lobe. The separate entity of the subapical segment of the lower lobe was recognized, and among the basal segments the axillary basal could be termed the lateral basal in accordance with modern terminology. We now suggest the following terminology of the broncho-pulmonary segments.

Upper lobe : apical, lateral, anterior, subapical.

Middle lobe : Anterior, lateral.

Lower lobe : apical, subapical, cardiac, anterior basal, lateral basal, posterior basal.

The anatomy of the broncho-pulmonary segments, and particularly of their vascular supply, has in recent years received such detailed consideration in connexion with pulmonary segmental resection as to add to that knowledge which has been the basis of the splendid life-saving advances made in recent years in the surgery of the lung.

"TRIDIONE*" IN THE TREATMENT OF EPILEPSY

BY

C. W. M. WHITTY, M.R.C.P.

(From the Department of Neurology, Radcliffe Infirmary, Oxford)

The oxazolidine diones, of which tridione is one, are structurally related both to the hydantoins and to the barbiturates. Another member of the series, dipropyloxazolidine dione, had been used some years ago (Luton *et al.*, 1941) as a hypnotic and anaesthetic, and when tridione was synthesized by Spielmann in 1944 it was originally

Oxazolidine diones Hydantoins Barbiturates

tried as a sedative and analgesic. However, in experimentally induced convulsions in animals it was found to be more effective as an anticonvulsant than either barbiturates or hydantoins (Everett and Richards, 1944). This observation, combined with the drug's low toxicity, recommended it for the treatment of epilepsy in man, and it has now been in clinical use for some three years.

The first report of its results was given by Lennox (1945), who noted that it was often dramatically effective in the petit-mal epilepsies, but that its expected anticonvulsant action as shown by the control of grand-mal seizures was not pronounced: on the contrary, it appeared occasionally to aggravate these. This view has been largely confirmed by subsequent workers (Richards and Perlstein, 1946: Perlstein and Andelman, 1946; Butter, 1948). Its value in psychomotor attacks also seems slight, though De Jong (1946) has claimed on rather slender evidence that, combined with other drugs, it is also effective in controlling these seizures. After two and a half years' experience of its use in 245 patients Davis and Lennox (1947) write of its "unique and almost specific effect in the control of the petit-mal epilepsies." This is a high claim for the treatment of a condition notoriously difficult to control, and may prove over-optimistic. Nevertheless all experience seems to agree that in many cases of petit mal tridione produces a striking amelioration.

Although the drug's toxicity in animal experiments was low, minor toxic effects in man are common. They were discussed in detail by Lennox (1947). He found complaints of a mild photophobia or "glare" effect—so that objects appeared as with a halo when viewed in bright light—the most common. This occurred in about one-third of all patients. Acneiform, morbiliform, and urticarial rashes were also noted, though they were usually transient. Indigestion and nausea might occur. Other occasional symptoms were drowsiness, ataxia, and irritability. Similar effects were reported in this country by Butter (1948). None of these symptoms was a serious hindrance to the continued use of the drug. However, there have also been reports of more severe toxic effects. These are of two main sorts—a reduction of blood-forming activity leading either to agranulocytosis or to aplastic anaemia, and an inflammatory skin reaction which may proceed to exfoliative dermatitis.

Fatal anaemia, or granulocytopenia, has been recorded in four cases from the United States (Harrison *et al.*, 1946; Mackay and Gottstein, 1946; Lennox, 1947), but at least one of these was taking "mesantoin" as well as tridione, so that the latter may not have been the responsible agent. In this country also two cases have been reported (Braithwaite, 1948; Forster *et al.*, 1949). Similar blood dyscrasias which responded to treatment have been reported in four other cases (Greaves, 1946; Briggs and Emery, 1949); while Kerrin (1948) detailed a case in which an urticarial rash led on to a fatal exfoliative dermatitis, and Butter (1948) mentioned a similar case which recovered. Barnett *et al.* (1948) and Briggs and Emery (1949) also record two cases with a nephrotic syndrome, one of which was fatal. These reported figures—eight fatalities and a further six severe reactions—must be considered in the light of Nattrass's (1949) quoted estimate of 10,000 cases that have had tridione treatment. In this context the toxicity of the drug cannot be viewed as very high, and Briggs and Emery must have been particularly unlucky in their experience of four severe reactions in a total of ten patients treated.

Apart from the above effects, Lennox also found that in half the cases of grand mal these fits were made worse.

The drug has not been extensively used in this country, owing partly to difficulties of supply and partly to its reputation for toxicity, which seems to have been exaggerated. Only three series, of 23, 10, and 9 cases respectively (Butter, 1948; Briggs and Emery, 1949; Nattrass, 1949), have so far been recorded. In this paper the results of the treatment of 50 patients are given.

Present Investigation

Case Material.—Patients were selected in the main because other forms of treatment had failed to control or reduce their attacks. Nineteen were males and 31 females, and their ages ranged from 4 to 62 years. Treatment was continued for periods varying from 2 to 18 months. Some form of the "petit-mal triad"* was present in 46 cases: 22 had only petit-mal epilepsies: the other 24 had grand-mal attacks as well. Six of these had proved local brain lesions as the probable basis of their attacks. Of the remaining four patients, three had grand mal only, and one a unilateral tremor-rigidity syndrome due to birth injury.

Dosage.—Dosage varied from 0.3 to 1.8 g. of tridione a day, which represented one to six capsules of 0.3 g. each. With adults the initial dose was usually one capsule three

*"Tridione" is Abbott Laboratories' trade name for 3,5,5-trimethyloxazolidine-2,4-dione. It has become established in the literature as the clinical name for this chemical substance and is therefore used here.

*This nomenclature was introduced by Lennox and Gibbs, and includes "classical" petit mal, myoclonic jerks, and akinetic or inhibitory epilepsy. The grouping seems justified on both clinical and electroencephalographic grounds, and is now accepted, with qualifications, both in this country and in America.

times a day, which would be scaled up or down in the light of their response. With children under 10, two capsules were used initially, and for those under 5, one. Once a marked beneficial effect was obtained the dose was usually reduced by stages to the minimum needed to maintain improvement. This was generally two or three capsules a day. Few patients who did not respond to three or four capsules a day would do so with larger doses, though in one case in which the smaller dose had produced no noticeable effect at all doubling the dose from three to six capsules a day produced a dramatic improvement in 48 hours. In some cases improvement was maintained even when the drug was stopped. For this reason the effect of omitting it was tried in all cases which still maintained improvement with only one or two capsules a day.

Results

Results were judged by comparing the average number of fits per week before and after treatment. Evidence of this was always obtained from an outside observer as well as the patient. It will be seen from Table I that five of the 22 pure petit-mal cases had their attacks completely

TABLE I.—*Cases with Petit-mal Triad Only*

Case	Age	Type of Attacks	Length of Treatment (Months)	Effect on Attacks
1	16	Pm., In.	6	Reduced to ½

abolished for the period of observation. In a further 11 cases attacks were reduced in frequency to a quarter or less. Another five showed slighter degrees of improvement, which in one case lasted only six weeks. In only one case was there no effect.

The assessment of the cases with mixed grand mal and petit mal is more difficult (see Table II). However, in 15 of them the petit-mal element was abolished or greatly reduced, and in a further five cases it was somewhat reduced. In four it was unaffected. The effect on the grand mal was hard to judge, as these attacks were usually much less frequent than the petit mal. A noticeable reduction of frequency occurred in five cases; in nine it appeared unchanged; and in ten it increased in frequency, or the fits became more severe, status epilepticus occurring in one case. Reviewing the whole 46 cases from the point of view of petit-mal attacks, 31 showed abolition of attacks or great improvement, 10 showed some improvement, and 5 showed no change; none were worse.

Of the six cases with focal brain lesions the petit mal was unaffected in three. In one, with a frontal glioma, attacks were reduced in frequency from three or four a day to two or three a month. In another, with a right temporal angioma, the petit mal was abolished for five weeks; then a severe status epilepticus occurred and tridione was abandoned. In a third case, with a calcified lesion in the left temporal region, inhibitory or petit-mal attacks were greatly reduced. The drug was stopped in nine cases: in three because improvement was maintained

TABLE II.—*Cases with Grand Mal and Petit-mal*

without it; in two because the effect on petit mal was transient or negligible; in three because grand mal was increased; and in one because of marked irritability and conduct disorder.

Of the three cases of grand mal only, one, a post-traumatic epilepsy from closed head injury, was completely free from fits for a period of over a year. She had been given tridione as both hydantoins and phenobarbitone had failed to reduce the number of her attacks. The other two had been wrongly diagnosed as akinetic attacks before the account of a trained observer made it clear that they were in fact mild grand mal. In neither case was the frequency of the fits affected. The patient with tremor-rigidity syndrome was given tridione for its supposed antispastic effect, but no objective change in his condition was noted after three months' treatment.

In general the results of this regime were shown within a week or ten days of its start. Often within 48 hours a reduction of attacks was remarked on. After three weeks' treatment with an effective dose, further changes in the petit-mal epilepsy were not usually seen, though an increase in grand mal, if it occurred, commonly did so after this time.

If seizures were abolished or much reduced for over three weeks it was usual to start lessening the dose of tridione. In most cases it was possible to do so without any relapse, though occasionally reduction by even one capsule a day caused increase of fits. In three cases the drug was stopped entirely after three to six months of treatment, and all three remained free from attacks for periods of two to four months. On the other hand, in some cases in which the drug was omitted inadvertently attacks recurred or became more frequent within three to four days. Moreover, in two cases omission of the drug because clinical response seemed slight produced an unexpected increase in petit-mal attacks, which were again reduced when it was restarted.

Two cases, one with grand mal only and one with myoclonic jerks and grand mal, showed an interesting

change in their attacks within ten days of starting tridione. Both noted a lengthening of the period of aura, in each case an epigastric one, so that they were able to sit or lie down before their grand-mal attacks developed, whereas previously they had had only the most momentary warning. They appreciated this change considerably, though in neither case was there any reduction in the frequency of attacks.

Illustrative Cases

The regime of treatment and the problems involved are illustrated in the following brief case histories.

Case 16: Petit Mal and Myoclonic Attacks Abolished by Tridione.—A boy aged 13 had had typical petit-mal attacks and occasional myoclonic jerks of the right arm and shoulder since the age of 4½. There was no personal history of grand mal or any family history of epilepsy. Attacks averaged 10 a day, but on bad days he might have 20 or 30. They were unaffected by 4½ gr. (0.29 g.) of phenobarbitone a day, which was making him sleepy. He was given 0.3 g. of tridione t.d.s and 1 gr. (65 mg.) of phenobarbitone b.d. After three days the attacks were much less frequent, and after a week they were abolished. They have been absent now for over a year, except when he omitted the tridione for periods of five and eight days. On each occasion the attacks recurred in 48 hours. He is now stabilized on 0.3 g. of tridione b.d.

Case 5: Petit Mal Controlled by Tridione. Grand Mal Occurred for First Time · Controlled by Hydantoin.—A youth aged 18 had had petit-mal attacks since the age of 7. There was no personal history of grand mal. One sister had petit mal. Attacks averaged one or two a day and were controlled for some years with 1 gr. of phenobarbitone b.d. At the age of 16 attacks recurred, and 1 gr. of phenobarbitone t.d.s. had no effect. He was given 0.3 g. of tridione t.d.s with 1 gr. of phenobarbitone b.d. The attacks ceased after 48 hours. The phenobarbitone was gradually reduced during six weeks. Occasional petit-mal attacks recurred three months later, averaging one in four or five weeks. Five months later he had his first grand-mal attack. He had three further attacks in the next 10 days. Then 1½ gr. (0.1 g.) of hydantoin b.d. was added to his tridione. No further grand-mal attack occurred for the next four months. Two petit-mal attacks occurred during this time. He is now regularly taking 0.3 g. of tridione t.d.s. and 1½ gr. of hydantoin b.d.

Case 14: Petit Mal Unaffected by Tridione; Grand Mal Developed.—A girl aged 12 had had petit-mal attacks since the age of 10. There was no history of grand-mal attacks, and the family history was negative. The frequency of attacks was 12 daily, and they were reduced in number for a few months by 2 gr. (0.13 g.) of phenobarbitone a day. This effect soon wore off. She was given 0.3 g. of tridione t.d.s. together with the phenobarbitone, but this was without effect. In one month dosage was increased to 0.3 g. of tridione five times a day. There was no effect in a further month. At this time the first grand-mal attack was reported, and 0.3 g. of tridione t.d.s. with 1½ gr. of phenytoin sodium ("epanutin") was given for two months. There were no further grand-mal attacks, but the petit mal was unabated. Electroencephalography in this case showed runs of typical wave-and-spike activity.

Electroencephalographic Changes

A detailed description of these will be given elsewhere. Here it is worth noting that clinical improvement did not always go hand in hand with decreased abnormality in E.E.G. records; nor was the occurrence of wave-and-spike or "petit-mal variant" patterns in a record essential for clinical or E.E.G. improvement to occur. Though the majority of those showing good clinical response did in fact show wave-and-spike activity, some cases without this improved markedly, and at least one case with a clear-cut wave and spike showed no clinical response to the drug.

Toxic and Other Incidental Effects

Blood changes are potentially the most dangerous and deserve special consideration. Reports of fatal blood changes have been mentioned above. They appear to be fairly sudden in onset and rapid in progress. In some of them both diagnosis and treatment seemed somewhat delayed. They may occur at any time within a few weeks to ten months of the start of treatment. As with other toxic blood dyscrasias, their earlier manifestations are probably general symptoms of sore throat, malaise, listlessness, etc. Their possible occurrence demands that patients on tridione should be under medical supervision, and unexplained general symptoms require an immediate check on the blood. They are, however, rare, and a more common effect noted by Davis and Lennox was a slow downward drift of the absolute neutrophil count, sometimes with a rise in number of lymphocytes or a transient eosinophilia. The change was reversed by omitting the drug.

In 36 of the cases in this series full blood counts were done at the start of treatment, thereafter fortnightly for the first six weeks, and then at intervals of four to six weeks. In 10 others the counts were done initially and at monthly intervals. In four the counts were more sporadic. In 26 cases treated for six months or more two showed a sudden marked reduction of total granulocytes in their monthly counts. Both returned to normal—one within 14 days and the other within four days of the abnormal count. In the latter case it was considered possible that the apparent reduction was due to a technical error. In six others a slow but irregular reduction of granulocytes was noted, but in none did the absolute neutrophil count fall to the 1,600 considered dangerous by Lennox. In four a moderate leucocytosis occurred, but at periods varying from one to 10 months after the onset of treatment, so that there was probably no causal link. In two an eosinophilia of over 5% was noted. No significant change in haemoglobin or red cells was seen.

The urine was tested, for albumin and sugar only, in 18 cases during the first three months of treatment. Albuminuria was found in one case. This was absent three weeks later, though the treatment had been continued.

Apart from the aggravation of grand-mal attacks considered above, other toxic effects, though annoying to patients, were medically trivial. Seventeen cases suffered from "glare." For this the wearing of sun-glasses during bright weather sufficed to allay any discomfort. Ten had rashes—eight acneiform, one macular, and one urticarial. In the latter two cases the drug was omitted for three weeks, as these rashes may sometimes herald more severe toxic reactions. The acne seemed purely an aesthetic disadvantage, though at times a serious one. In young women especially it proved a handicap to continued treatment, which had sometimes to be omitted temporarily. The rash would then clear, to return, though often less intensely, when the drug was restarted. Four patients had an irritability severe enough to affect their social relations. Three noted drowsiness and slight ataxia, and in one of them this persisted for some months. Three had prolonged bouts of hiccup during the first three months. None complained of indigestion, though two had nausea or vomiting at the onset. None of these complaints required more than a temporary cessation of the drug. It is a distinct advantage that its sudden complete cessation had no tendency to cause status epilepticus in patients with grand mal—a danger which always has to be borne in mind with barbiturates and hydantoins.

The obverse of these minor ill-effects should also be mentioned. In many cases patients or their relatives spontaneously remarked on an increased sense of well-being, an improved performance at school, or improvement in social behaviour in the home. One intelligent patient gave a vivid description of the increase in self-confidence when he no longer had to fear the sudden interruption of what he was saying or doing by an attack.

Discussion and Conclusions

There can be little doubt that tridione is a valuable remedy in the treatment of petit-mal epilepsy. At present it is used mainly in those cases in which phenobarbitone and the other better-established drugs have failed. In the future, it, or one of its less toxic related compounds such as dimethylethyloxazolidine dione, already in use in America, will probably be the drug of first choice. Its possible toxicity, especially to the blood, is a handicap, but as case material accumulates this will be seen to be a slighter risk than it appears at present. For the moment it should be used with circumspection, regular medical supervision and a routine monthly blood count being essential. As its use increases, a more serious disadvantage may be its aggravation or provocation of grand-mal attacks. For this the addition of some effective anticonvulsant will be required. Phenobarbitone may be useful here, but in this series the hydantoinates proved more valuable for combined therapy.

In the ten cases in which tridione seemed to activate grand mal this tendency was controlled in six by the addition of hydantoinates; and with these two drugs together three patients were rendered free from all fits for the first time for some years. Such a combination requires especial care in watching for blood dyscrasias, as both components are known to produce this effect. In practice, 17 of the above patients have been on this regime for periods up to 14 months, and so far no untoward results have been seen.

Short-term assessment of treatment in epilepsy is always apt to be misleading, because the frequency of the seizures tends to vary naturally, often for no apparent reason. Nevertheless, the first results of tridione therapy are striking enough to justify hope for the future.

Perhaps the most interesting question that arises out of this drug's marked selective effect on petit mal is that of its mode of action. Some valuable information on this point is provided by the findings of Grey Walter (1949 —personal communication). In patients who showed myoclonic jerks which could be fired off by photic stimulation, provided the frequency of the light-flash on the retina was exactly right, he found that administering tridione in a given case changed the frequency at which the light-flash would elicit the jerk. At first it appeared as if the light-stimulated response had been abolished; that the drug had "cured" this artificially stimulated epilepsy. But further stimulation with the light-flash at a changed frequency again produced the myoclonus, and it would seem that tridione had only altered the setting of the complex reflex pathway subserving the response.

In certain patients, at present few in number, the occurrence of clinical petit-mal seizures has been reported following intermittent stimulation of the retina by some incidental occurrence during their day's work (Cobb, 1947). In these cases any curative effect of tridione must work in a similar way to that demonstrated by Walter. If we consider that the central mechanism for firing off petit mal can be stimulated by other than photic afferent impulses—from exteroceptive and possible enteroceptive sources—then changing the rate of stimulus necessary to fire the mechanism would still provide a basis for clinical cure. There are many features in the clinical course of petit mal which would lend support to the view that incoming stimuli of various sorts help to precipitate the attacks.

Moreover, Jasper and Droogleever-Fortuyn's (1947) production in animals of generalized wave-and-spike cortical electrical patterns by stimulation of the internal laminar region of the thalamus also suggests the importance of the afferent system. Should these findings be applicable to human petit mal, then we must envisage the electrical changes in the cortex and the changes in consciousness that constitute the seizure as being activated from the thalamus. What causes the thalamus to fire in this way is still a matter for further experiment and speculation. But in interfering with the thalamo-cortical mechanism of the seizure tridione can presumably act at cortical or thalamic level or at both.

The findings from clinical use of the drug would suggest that some action at any rate is at cortical level. The "glare" phenomena support such a site, as does the change produced only in the aura phase of the two cases of grand-mal attacks. Moreover, the effect on seizures occurring in the three patients with known focal cortical lesions point the same way. If this is so, then the continued use of tridione may enliven clinical routine by the incidental light it sheds on cortical function as well as by its therapeutic success.

Summary

A review of 50 cases treated with tridione is given—22 had one of the petit-mal epilepsies only, 24 had mixed grand and petit mal, three had grand mal only, and one had a unilateral tremor-rigidity syndrome.

In 31 cases the petit-mal attacks were abolished or markedly lessened, in 10 they were reduced, and in five unaffected. Grand mal was reduced in five cases, unchanged in 9, and aggravated in 10, in one of which status epilepticus occurred.

Evidence of serious though transient toxic effects on the blood was shown in two cases. Other toxic effects included "glare," rashes, irritability, hiccup, drowsiness, and ataxia. Except for the first two, these were usually slight or transient.

The drug was discontinued in eight cases because it was ineffective or too provocative of grand mal, in three because improvement was maintained without it, and in one because of pronounced irritability.

The combined use of tridione and sodium diphenyl hydantoinate for the mixed epilepsies, and the possible mode of action of the former drug on the genesis of petit-mal seizures, is discussed.

Addendum

Since writing this paper an additional five cases have been treated with tridione for periods of three weeks to three months. In three cases petit mal attacks were reduced to one-quarter or less of their previous frequency: in two there was little or no effect. Of the 37 cases from the original series who were continuing tridione, four have now ceased to take it. Three of these cases have maintained their improvement for one to three months. Blood changes have occurred in a further two cases—in one there was a sudden drop in the absolute neutrophil count, which was reversed within three days by withdrawal of the drug; the other showed a slow reduction of neutrophils to 1,400. In this case the total leucocyte count at first rose, owing to a simultaneous increase in lymphocytes. This emphasizes the importance of a differential count.

My thanks are due to Dr. W. Ritchie Russell for facilities for carrying out these trials. Messrs. British Schering, Ltd., kindly provided samples of trimethyloxazolidine dione at the start of this work.

THE USE OF "TRIDIONE" IN PETIT MAL

BY

F. C. HAWARD, M.R.C.S., L.R.C.P.

Medical Officer, Chalfont Colony for Epileptics

"Tridione" was first used at Chalfont Colony for Epileptics in October, 1947. The following is a summary of the cases treated with this drug in the following year, with our conclusions.

As we knew little of the possible toxic effects of tridione the trial was limited to 50 cases, but we feel that these were sufficient to assess the efficacy of the drug. The patients were chosen at random; some suffered from petit mal alone and some from petit mal with grand mal. All cases of petit mal were diagnosed solely on clinical grounds. As tridione is effective only when petit-mal attacks are associated with a cortical dysrythmia of the wave-and-spike type, it is probable that some of the failures were due to the fact that the patients had a dysrhythmia of a different type. (Electroencephalographs were not available.) The ages of the patients ranged from 10 to 68, and they were mostly females.

Dosage

Each patient began treatment with one capsule (0.03 g.) thrice daily; the dose was to be increased to six capsules daily if no benefit was produced. In only three cases was it necessary to administer the maximum amount. Initially, tridione was given to all cases, whether they suffered from petit mal alone or in combination with grand mal, but it was soon realized that tridione does not control grand mal. Moreover, certain cases who had previously only suffered from petit mal began severe grand-mal attacks when given tridione alone. Two cases went into status epilepticus (with subsequent recovery). We agree with Lennox (1947) when he states that he does not regard the term "anti-convulsant" as correct when applied to tridione in its use in epilepsy. An anti-convulsant such as phenobarbitone and/or epanutin is now given in conjunction with tridione to all cases.

Duration of Treatment

Anxiety about the possible toxic effects of tridione led to withdrawal of the drug too soon in some of the early cases. The continued administration of tridione with an anti-convulsant might have led to improvement in these cases, and we are at present treating some of them in this way. We have so far completely withdrawn the drug in only one patient (quoted below), who has reacted successfully. Lennox states that after the withdrawal of tridione there may be no attacks for 18 months. We gradually reduced the dosage when the fits ceased or became much less frequent. A number of patients whose attacks were considerably reduced with tridione showed an increase in attacks when the drug was discontinued owing to some contraindication.

Immediate Effects

Tridione is beneficial in cases of petit mal, a condition which had previously appeared not to react to any form of treatment. The results with some patients, particularly children, were dramatic. Within a short time of the drug being administered there was complete relief in patients previously having frequent attacks. One typical case illustrates this:

T. F., aged 14 years 10 months. Admitted to Chalfont on April 29, 1943. He had suffered from 10 to 21 minor attacks per month for five and a half years. On Oct. 18, 1947, he was given tridione, one capsule t.d.s. Since that date he had one major attack, in November, 1947, and no epileptic attack of any type since. Prior to having tridione he was described as a "dopy" type of child; at present he is a bright and reliable boy and joins in all games with obvious enjoyment.

Apart from cessation or reduction of frequency of attacks, there has been improvement in behaviour defects and mental capacity in several cases, and the patients have expressed a feeling of general betterment. We have not been able to record improvement by the electroencephalograph, as the apparatus is not available. Lennox utilizes electroencephalography as an indication for reducing the dose of tridione. If his cases have had no petit-mal attacks for three months and the encephalograph is free of wave-and-spike formations, he reduces the dosage by one capsule every two months until none is taken, if the attacks do not return. When reduction or cessation of attacks is not accompanied by an improvement in the patient's mental state, this may be due to insufficient time having elapsed for the mental capacity to be judged. An improved mental state may follow, particularly in children and in cases with a short history.

In our experience the best results have been produced in children. Whether this is due to the age of the patient or the shorter duration of the malady we do not feel in a position to say, though Lennox states that the age is presumably the important factor. Age would appear to be no contraindication to the use of tridione. Our oldest case is a woman of 68, whose history is appended:

K. A., admitted to Chalfont on Nov. 12, 1931, with 27 years' history of epilepsy—all minor attacks. Her annual number of attacks was from 150 to 250. She was first given tridione on Nov. 21, 1947, since when she has had six to seven attacks per month.

In addition to the petit-mal attacks recorded by the attendants, presumably there are a large number which must escape observation.

One other factor in assessing the value of original treatment, particularly in adults, is the patient's suspicion of a new drug; in some cases this resulted in a lack of co-operation and hysterical manifestations.

Toxic Effects

Visual.—There were no serious toxic effects in our cases. Photophobia, or the "glare" phenomenon, particularly when the patient was out-of-doors, has been the most common manifestation, although this has occurred only in adults. There was no evidence of intrinsic eye changes. In no case was it necessary to discontinue treatment on this account, and the condition appeared to occur irrespective of dosage.

Blood.—White cell counts and haemoglobin estimations were done at monthly intervals. We had decided that if the count fell below a total of 4,000 white cells we would stop the drug. This occurred in one case, and the count improved considerably after the tridione had been discontinued. Lennox lays down that a white count of below 4,000, with polymorphonuclears less than 40% or numbering less than 1,600, are indications for at least temporary discontinuance of medication. The haemoglobin remained normal except in one case with a reduction to 60% ; there was no evidence that the diminution was due to the tridione.

Skin.—Two children developed a morbilliform eruption, one having in addition a severe stomatitis, presumably due to the drug ; the blood picture was normal. The condition cleared up shortly after tridione was discontinued.

Gums.—There was no effect on the gums, such as the hyperplasia that follows epanutin administration.

Ataxia.—There was no case in which tridione could be incriminated.

Indications for Stopping Treatment

These are: (1) an increase in the number of attacks, (2) failure to control petit mal, and (3) manifestation of toxic symptoms. The dose of tridione was increased to six capsules per day, when necessary, before we considered it had failed to control the petit mal. One important factor in the use of tridione is that, unlike the anti-convulsant drugs, it can be withdrawn abruptly without ill effects.

Summary of Cases

Children.—Fourteen cases.

Boys.—Ten cases, aged between 10 years and 14 years 11 months. Attacks have entirely ceased in four cases. In case 1 they ceased in seven months, in case 2 in six weeks, in case 3 in four weeks, and in case 4 in four months. Case 1 was having 100 attacks a month ; case 2, 65 attacks a month ; case 3, 10 to 20 attacks a month ; and case 4, 35 attacks a month. The remaining 10 cases showed from 10% to 90% reduction in the number of attacks.

Girls.—Four cases, aged between 11 years 11 months and 13 years 11 months. Case 1 was exhibiting the akinetic type of attack. She has ceased to fall in the attacks, and they were reduced by about 15%. In cases 2 and 3 the attacks were reduced by 50%. Case 4 had shown a marked reduction in her attacks, but after four months' treatment tridione was withheld when the total white cell count fell to 4,000 per c.mm.

Adults.—Thirty-six cases.

Females.—Twenty-six cases, aged between 16 years 10 months and 68 years. Attacks ceased in six months in one case that was having 120 to 300 attacks a year. Thirteen cases showed a diminution in the number of attacks. Seven cases showed little or no improvement. Three of these cases were among the earliest treated with tridione, and began severe attacks of grand mal as soon as therapy was started. Two of these cases are now receiving tridione again, and doing well. Two cases were apparently worse with tridione.

Males.—Ten cases. Of these, eight cases showed improvement and two no improvement.

From the foregoing it will be seen that in boys 28.5% showed cessation of attacks, and in girls 75% showed improvement. In female adults 3.7% showed cessation, 50% improved, and 7.7% became worse. In male adults 80% showed improvement, and 20% showed no improvement.

We are now giving tridione to more patients. The drug appears to be of use in all cases of petit mal, although it is of little or no value in the treatment of grand mal.

Summary

Conclusions are given of the treatment of 50 cases of petit mal with tridione over one year. Tridione is of value only in the treatment of petit mal. Dosage and toxic effects are discussed.

An analysis is given of the effects of treatment upon adults and children. The best results were with children.

My thanks are due to the committee of the National Society for Epileptics for their permission to publish these results, and to the matron and nursing staff for their co-operation.

CASE OF SALMONELLA ENTERITIDIS SEPTICAEMIA WITH LUNG ABSCESS

BY

I. McLEAN BAIRD, M.B., Ch.B.

AND

L. CAPPER, M.B., B.S.

(From the London Chest Hospital and the Seamen's Hospital)

Although *Salmonella enteritidis* (Gaertner's bacillus) infection is usually characterized by an acute gastro-intestinal illness with a pyrexia, many authors report a positive blood culture. Huang (1937) reviewed 50 cases of Salmonella septicaemia, most of which also had a coincidental debilitating disease—e.g., relapsing fever. There is a striking similarity between the features of *Salm. enteritidis* septicaemia and typhoid fever.

The usual onset of *Salm. enteritidis* septicaemia is sudden, with fever and generalized aches. A continuous fever with a relative bradycardia often occurs in the second week. A moderate anaemia with a leucopenia is frequently present. An enlarged spleen is almost constant. Rose spots about 3 mm. in diameter, not fading on pressure, are a feature at this stage. The blood cultures are positive in the first two weeks, and the organisms can be recovered from the stools and the urine later. Serum agglutinins are not usually detected until the fourth week.

Occasional variants from this clinical picture have been recorded—e.g., hepatic enlargement. Necropsy findings include hyperplasia of Peyer's patches, haemorrhages in the gastro-intestinal mucosa, and inflammatory lesions of the brain, gall-bladder, bile ducts, and lungs.

Predisposing Factors and Prognosis.—Most authorities stress the importance of malnutrition and debilitating disease, which is emphasized in the case report below. The mortality is high, and due to the frequent occurrence of complications.

Complications

The complications recorded include meningitis, pyelitis, osteomyelitis, cholecystitis, cholangitis, and pulmonary

involvement. Two cases of fatal purulent meningitis are recorded by Huang. Stevenson and Wills (1933) have reported a "primary" *Salm. enteritidis* meningitis in a child of 9 weeks. Pyelitis and pyelonephritis are common in the recorded cases. Harvey (1937) and Guerra have reported the occurrence of *Salm. enteritidis* osteomyelitis. Barwell (personal communication, 1947) describes a case of amoebic liver abscess in which *Salm. enteritidis* (Chaco variety) was found in the pus from the abscess.

Pulmonary Involvement.—The recovery of *Salm. enteritidis* from the sputum has often been reported, but only two cases of pulmonary involvement could be found. McNee (1921) describes a case of "influenza bronchopneumonia" in which necropsy findings were haemorrhagic peribronchial areas with pus in the bronchi, from which *Salm. enteritidis* was cultured. Smith and Scott (1930) report a case of *Salm. enteritidis* septicaemia in which consolidation of the right upper lobe developed. The rarity of the pulmonary involvement is contrasted strikingly with the comparative frequency in typhoid and paratyphoid fevers and in infection by *Salm. cholerae-suis.*

Case Report

A merchant seaman aged 48, a native of Barbados, was admitted to the Seamen's Hospital on Feb. 6, 1946. He complained of several weeks' headache and sweating. He also had some shortness of breath and had recently developed anorexia with occasional vomiting. He had a history of malaria and had been treated for nutritional oedema in 1945 at Durban.

On admission his temperature was 101.4° F. (38.55° C.), but there were no abnormal physical signs except a furred tongue and a dermatitis on his back and arms. The initial white-cell count was 12,900 (82% polymorphs) and the blood urea 49 mg. per 100 ml. The urine contained albumin, pus, and a few red cells. The chest showed no radiological abnormality at this stage.

Pyrexia continued, with peaks of 104 to 105° F. (40 to 40.6° C.), and six days after admission a course of quinine and mepacrine was tried empirically. The pyrexia did not respond to this therapy. Twelve days after admission he developed a coliform cystitis which responded to potassium citrate, and he became afebrile for a week, with much clinical improvement.

On the 24th day after admission he again became febrile and developed a cough with "rusty" sputum. Examination revealed fine crepitations over the right upper lobe and signs of a small effusion at the left base. A skiagram now showed the presence of a thick-walled abscess cavity in the right upper lobe and a small left basal pleural effusion. Further radiological examinations during three days showed an increase in size of the abscess, which lay in the axillary-pectoral segment of the right upper lobe. A second smaller cavity developed in the left upper lobe, but this diminished in size subsequently.

The patient's condition slowly deteriorated, and he was soon producing 4–6 oz. (110–170 ml.) of foul sputum daily. There was no response to penicillin or sulphonamide therapy, and on March 22 he was transferred to the London Chest Hospital for surgical drainage. At this stage his main complaint was a sharp pain in the right side of the chest, and his temperature was continually about 101.6° F. (38.7° C.). Clubbing of the fingers had not developed, but the dullness at the right upper lobe and showers of fine crepitations were still present. His white cells numbered 34,000 (polymorphs 70%), and his haemoglobin was 66%.

A course of penicillin (500,000 units daily) was again started, and on March 24 the abscess was drained through the axilla. Specimens of pus from the abscess, the sputum, and the blood all produced *Salm. enteritidis* on culture. However, the patient became stuporous two days after the drainage and developed marked meningism. The cerebrospinal fluid was sterile on culture, and there were no abnormalities in pressure or cell count. The patient's condition gradually deteriorated, and generalized oedema developed. He died on April 4, eight weeks after his original admission.

Necropsy revealed a marked increase in intracranial tension, with numerous abscesses and septic infarcts but no meningitis. The whole of the right upper lobe of the lung consisted of a sloughing pneumonitis with central cavitation, and there was a thin-walled abscess in the left upper lobe. Ulceration of the ascending and lower descending colon was present, non-specific in character. The liver and spleen were normal.

The bacteriological investigation (Dr. Joan Taylor, Salmonella Reference Laboratory) showed that this particular organism was the Chaco variety of *Salm. enteritidis*, which had been isolated in India and South America but not previously in this country.

We are indebted to Dr. E. H. Hudson, Dr. Keith Simpson, Dr. C. E. Sundell, and Mr. Vernon Thomson for permission to publish this case and for their helpful criticism.

Medical Memoranda

Direct Inspection of Coarctation of Aorta with a Thoracoscope

A study of the literature reveals that a coarctation of the aorta has never been reported as having been seen through a thoracoscope, nor has the use of this instrument as a means of identifying abnormalities of the great vessels been described, though Fatti (1949—personal communication) used the procedure before performing Blalock's operation.

In the case here described there was a chance combination of two diseases—coarctation of the aorta and pulmonary tuberculosis. A therapeutic pneumothorax was induced and the presence of adhesions indicated thoracoscopy. An opportunity for direct inspection of the coarctation was thus presented. We were able to confirm the presumptive diagnosis and to determine the exact position and extent of the lesion and its relation to the subclavian artery.

Case Report

The patient, a woman aged 22, had a haemoptysis in July, 1948. She was *x*-rayed, and pulmonary tuberculosis was diagnosed.

On admission to the tuberculosis unit of St. Stephen's Hospital she felt well, had only a slight cough and a trace of sputum, had not lost weight, but had had some headaches which were not severe. The feet were always cold, even though she used a hot-water bottle to try to keep them warm.

Her general condition was good: she was afebrile and her weight was 7 st. 12 lb. (49.89 kg.). There were no physical signs of pulmonary disease. Examination of the cardiovascular system revealed a normal-sized heart with a blowing systolic murmur heard all over the praecordium, and equally well heard in the interscapular region, especially on the left side. The blood pressure was 200/95 in the right arm, 210/90 in the left arm, 190/100 in the right leg, and 190/100 in the left leg. There was visible and increased carotid pulsation, but no evidence of abnormal collateral circulation over the chest wall. The femoral pulses, though present, were difficult to feel, and were later than the radial pulses.

A radiograph of the chest showed diffuse miliary-type infiltration throughout the left lung. The right side was normal, as was the heart size; the aortic knob was small, and the pulmonary conus was not enlarged. There was no rib-notching. The electrocardiogram was normal. Sputum once showed scanty tubercle bacilli.

A diagnosis of pulmonary tuberculosis complicated by a mild degree of coarctation of the aorta was made. Dr. Paul Wood, who saw her in consultation, thought that the diagnosis of coarctation of the adult type was likely.

After a period of bed-rest and para-aminosalicylic acid the patient's condition was even better than on admission; her erythrocyte sedimentation rate had fallen from 30 to 7 mm. Westergren. The radiograph was unchanged. Tomography showed a cavity in the left infraclavicular region. A left artificial pneumothorax was induced on Feb. 16, 1949, without incident. Adhesions were present. In the absence of evidence of gross chest-wall anastomoses thoracoscopy was considered to be a justifiable procedure.

The operation was performed by one of us (J. R. B.) on March 4. The few apical adhesions which were present were divided without haemorrhage from the cut ends. After this the aorta was examined both above the upper lobe and through the fissure, and the whole length from arch to coarctation was seen. The notch was easily visible at the posterior end of the fissure, and was rather deeper than had been anticipated from the clinical picture. It was a short constriction and well below the origin of the left subclavian artery—the second type described by Salén and Wiklund (1948). Convalescence from thoracoscopy was not complicated by intrapleural haemorrhage.

COMMENT

Since Gross (1949) reported a case in which a graft had been successfully implanted in a boy in whom a long segment of aorta had to be removed in order to excise the stenosed segment completely, an accurate pre-operative diagnosis of the anatomy of the coarctation has become more important.

The method of angiocardiography using a systemic vein as the site of injection does not give very satisfactory results owing to excessive dilution of the medium. As an alternative, dye may be injected by introducing a catheter through the brachial artery, as has recently been done in Scandinavia.

It is suggested that there may be a place for thoracoscopy, as a view of the actual lesion must be far more informative than any radiological technique. The risk entailed must necessarily be haemorrhage from the anastomotic vessel on the chest wall, and, although this problem was not encountered in our case, it was not one in which complete obstruction was present. To avoid this risk it may be wise to introduce the thoracoscope high up, possibly in the second space anteriorly. Rib-notching is seldom seen in the upper two or three ribs, which may indicate that the collateral circulation is not extensive at this level, although J. Chesterman (1949—personal communication) states that the vessels are greatly dilated in all the intercostal spaces in specimens he has had the opportunity of investigating by injection at necropsy.

We would like to thank Mr. T. H. Holmes Sellors and Dr. Alec Wingfield for their encouragement.

Artificial Pneumoperitoneum Associated with Strangulated Hernia and Scrotal Pneumocele

It has not been possible to find an account of strangulated hernia complicating artificial pneumoperitoneum treatment. The following case is therefore recorded.

CASE REPORT

A man aged 22 was referred to the Bedford Chest Clinic in October, 1946, because of persistent tachycardia. An x-ray film on Oct. 22, 1946, showed shadowing in the left upper zone, suggesting tuberculous infiltration. The right lung was clear. An artificial pneumoperitoneum was induced on Jan. 19, 1947. A left phrenic crush was done on Feb. 15. A rise in position of the left diaphragm of approximately 3 in. (7.5 cm.) was obtained by these means. The patient has done no heavy work since his lesion was diagnosed. His refills have been given at approximately ten-day intervals, 1,000 c.cm. in amount. His final pressure has averaged +4 to +6, and the highest ever recorded was +9 on two occasions in November, 1947.

His left phrenic nerve was recrushed on Feb. 14, 1948. He was last refilled on Oct. 1, 1948. Final pressure +3 to +6.

About October, 1947, he had noticed a small painless "lump" below the right inguinal canal. On Oct. 5, 1948, he noticed a sudden increase in the size of the swelling. Severe pain developed accompanied by vomiting. Six hours later a tender tense swelling was present in the right inguinal region, extending into the scrotum and reaching the upper pole of the right testicle. The swelling was irreducible, size about 3½ in. (8.75 cm.) long by 1 in. (2.5 cm.) wide. After administering morphine and atropine the hernia was reduced by taxis with some difficulty. Immediately following this procedure the right side of the scrotum became distended to about the size of a grapefruit. The testicle was covered but could be felt below the swelling, which was not tender. This swelling could be easily reduced, but it rapidly re-formed. It was undoubtedly caused by air. A pressure pad placed over the external ring retained the swelling without difficulty.

An operation for right inguinal hernia was performed. An air-distended processus vaginalis was demonstrated, dissected down, and found to include the testis.

COMMENT

The interest in this case lies in the fact that no reference has been found in the literature to the occurrence of strangulated (incarcerated) hernia accompanied by a scrotal pneumocele complicating pneumoperitoneum treatment. Meltzer (1948) describes a case of scrotal pneumocele, and quotes four others as the only cases that he has found in the literature. Nagley (1948), however, quotes a case of inguinal hernia, and also adds three cases of scrotal pneumocele. Bennett (1938), in a review of 200 cases of pulmonary tuberculosis treated by pneumoperitoneum, had three cases of hernia develop, none strangulated, but treatment was discontinued. Rilance and Warring (1944) report a case of a patient who had a small inguinal hernia sac which was filled with fluid from the peritoneal cavity by coughing. This could not be reduced until 25 ml. of fluid was aspirated. Daniels and Eisele (1938) describe two cases of inguinal hernia in which increase in the size of the scrotum occurred during pneumoperitoneum treatment. This they ascribed to air. Banyai (1946) also quotes two cases of inguinal hernia, not started by pneumoperitoneum treatment, but made worse by it. Crow and Whelchel (1945) report an emphysematous type of inguinal swelling occurring in something under 2% of 546 patients. They treated this by reduction of the swelling and the fitting of a truss.

Refills were then continued without further trouble. A number of other authors have quoted similar experiences.

It is obvious that hernia complicating artificial pneumoperitoneum treatment is common. It is clear that it can be well controlled by a truss, that this should be done, and that the pneumoperitoneum need not be discontinued. Scrotal pneumocele, until lately looked upon as a rarity, is probably more common than hitherto thought.

N. WYNN-WILLIAMS, M.B., M.R.C.S.,
Physician in Charge of Bedford Chest Clinic.

Haematemesis Following Intraduodenal Rupture of Aneurysm

The frequency of occurrence of aneurysms of the abdominal aorta and its branches is now well recognized. Bryant (1903), examining necropsy records at Guy's Hospital, found, over a period of 46 years, 325 cases of aneurysm of the aorta, 54 of which were abdominal. Of Lucke and Rea's (1921) series of 321 aortic aneurysms 40 were abdominal, as were 6 of 94 aortic aneurysms recorded by Levitt and Levy (1940). Kampmeier (1936) found 386 cases reported in the literature, which was reviewed by Jennings (1941), who added four further cases and stressed how varied and dramatic may be the presenting clinical picture.

American authors seem to regard syphilis as the major aetiological factor in the development of these aneurysms, whereas in this country the combination of atherosclerosis and continued heavy manual work is generally held to be responsible, a view that is supported by the predominance of males among reported cases. In untreated cases the expectation of life from the time of diagnosis appears to be little more than a year, death being due to rupture of the aneurysm and haemorrhage.

In the majority of cases rupture is either retroperitoneal or intraperitoneal. Bockus (1943), in discussing the causes of haematemesis, refers to the possibility of aneurysmal rupture into the stomach but does not quote any recorded instances. Perry and Shaw (1893) reported a case of a man aged 37 in which at necropsy "at the lower end of the duodenum" there was a small orifice opening into the sac of an aneurysm "which sprang from the centre of the abdominal aorta." The stomach, duodenum, and parts of the small intestine were full of blood clot, but death was sudden and the occurrence of haematemesis was not described. Scott (1944) refers to a patient whose death was due to massive gastro-intestinal haemorrhage following rupture into the duodenum, but no clinical history is given. No other reports of rupture into the duodenum have been found in the more readily available literature.

The following case seems to be of particular interest, the patient being a female and death being preceded by haematemeses recurring over a period of nearly 24 hours.

CASE RECORD

A widow aged 58 was admitted to Edgware General Hospital at 11.30 p.m. with a history of having vomited approximately 10 oz. (280 g.) of blood-stained gastric contents 12 hours and six hours previously. For the preceding five months she had felt generally unwell, with poor appetite, distaste for food, and occasional upper abdominal discomfort which bore no definite relation to the taking of food. There had been no earlier history of dyspepsia and no loss of weight. Bowel action had been normal and there had been no observed abnormality of the stools.

The patient was a well-preserved co-operative individual; her general condition was good and not indicative of any great blood loss. Haemoglobin was 70% (Haldane). The abdomen was soft, and in the region of the umbilicus was a tumour, about 7 cm. in diameter, showing the characteristic sign of expansile pulsation. Pulsation of the tumour was visible through the anterior abdominal wall, but there was no palpable thrill and no bruit was audible on auscultation over the tumour. There were signs of moderate cardiac enlargement, considerable sclerosis of peripheral arteries was present, and the blood pressure was 140/85. A barbiturate hypnotic was prescribed and the patient spent a comfortable night, but at 8.30 a.m. the next day there was a further haematemesis leading to collapse and death.

Glass rod passed through connecting stoma.

A post-mortem examination was made by Dr. H. C. Moore. A large saccular aneurysm was present, arising from the main trunk of the abdominal aorta, which showed severe atheroma though no adventitial thickening. The aneurysm extended anteriorly and was filled with blood clot, removal of which revealed a stoma opening into the third part of the duodenum. The stomach and intestines were filled with blood. Sections of the aortic wall were reported as showing marked atheroma of the intima and, in the media, diminution of elastic and muscle tissue with collagenous replacement; in one place the media was absent. Mild lymphocytic infiltration of the media was present, and in the adventitia there was also some perivascular lymphocytic infiltration; no plasma cells were seen. There was no evidence of medionecrosis.

My thanks are due to Dr. H. C. Moore for assistance with the pathological examination, to Miss M. Shaw for the clinical photograph, and to Dr. L. I. M. Castleden for permission to publish this report.

According to the third annual report of the Institute of Child Health in the University of London, the Institute has been considering the possibility of obtaining its own premises. The new Board of Governors of the Hospital for Sick Children, Great Ormond Street, was consulted, with the object of seeking agreement on a joint policy of building and development. This policy has now been decided upon, and plans being considered include the completion of the hospital's buildings. The Institute has been stimulated in this course by a gift of £105,888 received last year from the people of Durban and the Province of Natal. The close association between the University and the Institute has been continued, and lecture-demonstrations have been given for D.P.H. students and for students of the London School of Economics. An account of progress in research supported by the Institute and the Hospital for Sick Children is appended to the report.

Reviews

RECTAL SURGERY

The Principles and Practice of Rectal Surgery. By William B. Gabriel, M.S., F.R.C.S. Fourth edition. (Pp. 508; 11 coloured plates and 278 illustrations. £2 5s.) London: H. K. Lewis and Co. 1948.

Sixteen years have elapsed since Mr. Gabriel published this excellent book, which is one of the standard works on the subject and is studied by all who undertake the treatment of lesions of the ano-rectal region. During this period, when so many matters have been in a state of flux, surgery has progressed along many lines, knowledge has increased, operative technique has advanced, and new operations have been perfected. In this surge forward rectal surgery is in a place of prominence and has become a specialty resting upon the safe foundation of anatomy, physiology, and pathology, with a sound superstructure of symptomatology, diagnosis, and treatment. Proctology in this country is practised by surgeons trained in general surgery who continue their work in the latter subject.

The appearance of the beautifully illustrated fourth edition is appreciated, since the subject matter has been revised carefully to incorporate the latest developments. In addition, a new chapter on anal incontinence is presented. The sad plight of patients with this condition is obvious and their gratitude for relief without the institution of a colostomy is unbounded. The author discusses all the varieties of anal incontinence and warns against unskilled and injudicious deep division of the external sphincter and ano-rectal ring for the cure of fistula, which is especially liable to happen with high-level fistulae anterior to the transverse anal line, particularly in women. Anal incontinence may, of course, follow several other operations on this region, and the chapter should be studied by younger surgeons who contemplate carrying out these procedures. The correction of the condition by various operations is described in detail and illustrated by helpful diagrams. I am glad to note the author advocates the use of unabsorbable sutures with an aseptic technique, pointing out that the use of an absorbable suture may account for the comparatively poor end-results in the past.

The part of the book concerning malignant disease is important, and reflects the mature wisdom of a surgeon who has studied the subject in detail from every viewpoint, often in collaboration with Cuthbert Dukes. As the result of his experience he prefers the one-stage perineo-abdominal excision, which has given him a 75% five-year survival rate in group A patients. Other operations, including anterior resection and proctosigmoidectomy, which are being studied earnestly at the present time, are discussed in a most helpful manner. The author incorporates the warning that we should adopt a cautious attitude until comparable statistics are available, "and the death of W. Ernest Miles in September, 1947, is also a sad reminder of the fact that his abdomino-perineal excision has now been the standard procedure for forty years, and it is not lightly to be discarded." Consideration is given to the so-called "inoperable" carcinoma. I feel the time has come to delete this term, for at best it is only relative and its attachment to a patient means the abandonment of hope. The author rightly demands, "When is any particular growth to be considered inoperable?" and he supplies the answer by stating it can be given only in most of the advanced and borderline cases when laparotomy is undertaken by a surgeon with special knowledge of this branch of surgery.

It is hoped that in a future edition more details will be given concerning the subject of sacro-coccygeal tumours, including teratoma and chordoma. Doubtless a section will be added on carcinoid tumours, which are being discovered in increasing numbers.

I express my indebtedness to the author for all the contributions he has made to rectal surgery, praise his book, and commend it to surgeons who seek to relieve the intense suffering occasioned by ano-rectal disease.

RONALD W. RAVEN.

ESSAYS ON SURGERY

Surgery Orthodox and Heterodox. By Sir William Heneage Ogilvie, K.B.E., D.M., M.Ch., F.R.C.S., Hon. F.A.C.S., Hon. F.R.C.S.Canada, Hon. F.R.A.C.S. (Pp. 241. 12s. 6d.) Oxford: Blackwell Scientific Publications.

The author has collected in this volume reprints of articles he has published at various times during the last few years. They range from addresses to students and professional societies to papers on highly technical aspects of surgery. Throughout they give evidence of the wide interests of the author, of his great surgical experience, and of his clear insight into the many problems which have confronted him. The descriptions of his own cases are the most attractive feature of the volume, and they are certainly examples, which any student should study, of how cases should be described. Indeed, there are few surgeons, however great their own experience, who will not learn something from their perusal. Even those articles outside the field of technical surgery have a wide interest, and should appeal to many readers whose interests are not restricted to the world of medicine.

H. S. SOUTTAR.

TABULATED THERAPEUTICS

A Course in Practical Therapeutics. By M. E. Rehfuss, M.D., F.A.C.P., F. Kenneth Albrecht, M.D., and Alison Howe Price, A.B., M.D. (Pp. 824; 70 plates. £4 2s. 6d.) London: Baillière, Tindall and Cox. 1948.

This great book, which in appearance is not unlike a family bible (it is beautifully printed and illustrated), has evolved from the method of undergraduate instruction in Jefferson Medical College, Philadelphia. For some years each student was assigned to review a particular therapeutic subject in internal medicine. Their contributions were then considered by the members of the department best fitted to do so, revised, edited, mimeographed, and given out to the class. In this way a huge quantity of material gradually accumulated and has been incorporated in the present volume. One feels the result is indeed the product of some great organization rather than of a few individual writers. As the pages are scanned one can almost hear the whirring of holleriths, the clicking of massed typewriters, and the hurrying feet of bands of busy amanuenses. And yet the result is co-ordinated, wonderfully well balanced, and lacking in contradictions. Somewhere in the background there has been a meticulously efficient secretary to the organization (probably a woman) and a remarkably well informed editorial board.

The book is planned in four sections. The first and shortest is an introduction to the principles of treatment by the senior editor. It is the only section to be written in a consecutive prose style, the other three being set out in tabular notational form. The second section is devoted to a discussion of symptomatology and its management. The third is concerned with the therapeutics of definite diseases, some consideration being given to aetiology and diagnosis, since it is realized that the successful description of treatment demands some preliminary classification and definition of the disease to be treated. The fourth section is on special forms of therapy.

In a rapid survey of the book I have been unable to find a single important drug or method of treatment which does not receive mention. In spite of the fact that such a large volume must have taken a considerable time to pass through the press, it is nevertheless remarkably up to date, even in respect of the most modern forms of antibiotic treatment. The main criticism of the work, and it is a serious one, is that too many methods of treatment are described without adequate critical assessment of their relative values. The reader is dumbfounded by the number of things he can do for a patient, but is left in some doubt about which is most important and when to do it. Embarrassed by his riches, he may feel like the celebrated ass which starved between two bundles of hay because it could not make up its mind which to turn to first.

This is manifestly not a book to read through, but one to use as a work of reference. A lecturer anxious to deal with any aspect of the therapeutics of internal medicine will here

find his notes beautifully prepared for him; and should anyone in this country think of editing a booklet on medical treatment he will find it easy, with the help of this volume, to ascertain how far the information given by his contributors is accurate, up to date, and comprehensive.

D. M. DUNLOP.

NOMENCLATURE OF DISEASE

The Nomenclature of Disease. Drawn up by a joint committee appointed by the Royal College of Physicians of London. Seventh edition. (Pp. 385. 8s. 6d.) London: H.M. Stationery Office. 1948.

The appearance of the seventh edition of this work coincides with the publication of the *International Statistical Classification of Diseases, Injuries, and Causes of Death* (*British Medical Journal*, April 30, p. 771). The purpose of the nomenclature is to lay down an approved terminology and to list the separate disease entities and parasites which in the light of current knowledge are believed to exist, giving in most instances only the recommended name for each. A statistical classification, on the other hand, has to group together into numbered categories, in a manner thought to be most useful for statistical presentation and research, all descriptive terms likely to be found on medical records. For each of these systems some form of combined aetiological and anatomical framework has to be used, and to some it may seem unfortunate that the system newly adopted for this edition follows the plan of the American standard nomenclature of disease rather than the simpler one which has stood the test of time in the international list. However, there are advantages as well as disadvantages in having a diversity of system between the nomenclature and the statistical classification.

The distribution of diseases according to aetiology within each anatomical section was entrusted to one, two, or three experts in diseases of that part of the body, and this has resulted in a certain lack of consistency between the sections and loss of balance in the amount of detail devoted to them in the index. What is more important, there are differences in aetiological assignment of some diseases between the nomenclature and the international classification. Hodgkin's disease, for example, placed among the neoplasms by overwhelming opinion from many countries in the course of constructing the international classification, finds an uneasy place under several headings in the nomenclature, only the bone deposits being grouped as neoplasmic. Some diseases, such as haemorrhagic disease of the newborn, appear in two different sections.

The list of eponyms and the list of plant and animal parasites (which occupies 59 pages) will possibly prove to be the most useful parts of the volume. The index contains more than 15,000 items, including references to the parasite section. In course of its preparation the book was placed at the disposal of those responsible for preparing the index to the international classification, which will contain many more terms, not all to be recommended, however.

PERCY STOCKS.

ARTERIAL DISEASES

Vascular Diseases in Clinical Practice. By Irving Sherwood Wright, M.D. (Pp. 514; 104 figures. £2 1s.) Chicago: Year Book Publishers Inc. London: H. K. Lewis.

Arterial disease is man's greatest natural enemy after middle life. His chance of dying from such disease or from its effects on the heart and kidneys is then probably five times as great as his risk of death from any other single cause.

Dr. Irving Wright's book considers all the well-known and lesser-known diseases of the arteries and veins, but not the resultant morbid changes in the heart, brain, kidney, and other viscera. An account of the methods of examination includes not only detailed descriptions of clinical methods, such as Allen's test for patency of the ulnar artery, but also such practical points as the great variation in the position of the dorsalis pedis artery and the fact that some individuals have such a distinct pulse in their own finger-tips they cannot use them reliably for palpation. Although oscillometry, angiography, and other instrumental methods receive attention, emphasis is placed throughout upon clinical procedures.

In connexion with the aetiology of arteriosclerosis, the author has little to add to the well-known factors such as heredity and an excess of cholesterol, lipoids, and fatty acids in the blood. Conversely, he sees only one important agent in the causation of thrombo-angiitis obliterans, namely, tobacco. He insists that every patient with this disease must give up smoking altogether and for good, and he states that every one of his 300 or more patients who have required major amputation has continued to smoke, often surreptitiously. Moreover, he predicts that sympathectomy operations will fail in their main purpose if smoking has not been abandoned. Most physicians will agree that tobacco is also disadvantageous in the degenerative types of peripheral vascular disease; this being so, it is remarkable that abstinence from tobacco so rarely alleviates the symptoms of myocardial ischaemia.

This work deals with many other interesting problems, among them the role of the cervical rib and the scalenus anticus in the production of vascular and neurological symptoms in the arm, as well as the disputed costo-clavicular syndrome and the effects of hyperabduction. The book is enlivened throughout with graphic clinical examples illustrating the points under discussion. In short, it is a first-class guide by which the clinician may orientate his own experience, and a stimulating exposition of a rapidly growing subject.

K. SHIRLEY SMITH.

THE SCHOOL CHILD

Everyday Problems of the School Child. By Agatha H. Bowley, Ph.D. (Pp. 142; 11 photos. 7s. 6d.) Edinburgh: E. and S. Livingstone. 1948.

A new book by Dr. Agatha Bowley is always welcome, because she writes clearly, interestingly, and sensibly. This volume is primarily intended for teachers, and gives advice on the handling of the child throughout his school life. Dr. Bowley founds her advice on psycho-analytic principles, but never becomes technical, obscure, or extreme. In fact, the whole story reads extremely like practical common sense, which is a tribute both to the author's presentation and the fundamental soundness of modern psychology when shorn of the excrescences which are often derived from a lack of practical understanding of human nature.

Two chapters discuss the relationship of teachers to child and parent, the rest being devoted to a consideration of the problems met at each stage of the child's career from nursery to secondary school. It may be asked what such a book has of interest to the medical reader, but neither the paediatrician nor the child psychiatrist, and still less the family doctor, can afford to lack a full understanding of the child at school. If the doctor is to keep the child healthy and treat him when he becomes ill in mind or body, he must realize what the child is experiencing intellectually, emotionally, and spiritually during the school life which takes up so much of his waking time. If the practitioner wishes to obtain at least a general understanding of this subject without having recourse to the more erudite textbooks of child psychiatry or education, he cannot do better than spend a wet Sunday afternoon reading Dr. Bowley's admirable little book.

R. G. GORDON.

CHILD GUIDANCE

Handbook of Child Guidance Edited by Ernest Harms. (Pp. 751. No price.) New York City: Child Care Publications.

Dr. Ernest Harms has gathered together many workers in child guidance; each has written on some aspect of theory or practice; and the result is a book of 751 pages of beautiful paper.

Every feature is covered: one wonders whether any more need ever be written on the subject. It may be that from now on the matter of child guidance must be considered closed. Every library should have this volume on its shelves, and there

are probably people who, unlike this reviewer, love to read books of 751 pages which cover everything.

I have looked through the pages for annoying features and obvious errors, and I cannot find any. The English is clear and good. There is even an attempt to present Freud's and Jung's theories which must be described as serious. Francis G. Wickes's chapter on Jung's theories is one of the best. Beside this there are references to Anna Freud's work, and there are attempts to state or evaluate a few of Melanie Klein's concepts.

I have also looked for an original idea, and the fact that I have not found one must not be taken as meaning anything. Such volumes can easily be burial grounds for new ideas. In any case the book remains a monument to the personal drive of Dr. Harms.

D. W. WINNICOTT.

BESNIER'S PRURIGO

Clinical Studies of Besnier's Prurigo. By P. H. Nexmand. (Pp. 236; illustrated. No price.) Copenhagen: Rosenkilde and Bagger. 1948.

This is a factual survey of a series of one hundred cases of Besnier's prurigo, observed over an average period of six months. The syndrome is regarded as something apart from eczema, which to the author is a vague and uncertain group of itching affections of unknown aetiology. Nevertheless, infantile eczema commonly precedes Besnier's prurigo and is often localized to the flexures of elbows and knees at this early age.

Little credence is given to the significance of the psychological basis of Besnier's prurigo, attention being directed almost entirely to the allergic aspect. Elaborate investigations by patch, scratch, electrophoretic, and intradermal methods revealed no very certain relationship to foods or inhalants, including pollens, moulds, house dust, and animal or human dander. Treatment by desensitization and by ultra-violet light is described, but better results were obtained in a shorter time and at less expense by local therapy. Antihistaminic drugs, employed over short periods in eight cases, did not appear to be of much value.

The author draws attention to the occurrence of perlèche in a number of his patients. Ichthyosis was present in only six cases and cataract in one case. He has observed a significant increase in the incidence of the disease during the past ten years.

J. T. INGRAM.

While the standard limb-lead electrocardiogram remains sufficient for the examination of arrhythmias, it is now widely recognized as inadequate for the study of myocardial disease. This fact has been taken into account by Burstein and Bloom in the third edition of their *Illustrative Electrocardiography* (pp. 309; illustrated; $6.00. New York and London: D. Appleton-Century Company, 1948). They have discussed in the first two-thirds of their work the well-understood principles of electrocardiography and the arrhythmias, describing the conventional leads and sometimes an additional lead, IV R or IV F. The chapter on the electrocardiogram in myocardial infarction would be quite inadequate without the supplementary section (later in the book) on "the fourth and other precordial leads"; no doubt in future editions these passages will be integrated and the obsolete designation "fourth lead" dropped. The authors have given a useful survey of the development of unipolar limb leads. They emphasize the manner in which curves from these leads relate to the posture of the heart and demonstrate that apparently abnormal Q or S waves in limb leads may prove to be positional when unipolar leads are used. With so much that is new in electrocardiography it is surprising that the authors have seen fit to include sections on phonocardiography and the radiology of the heart. Moreover, neither of these subjects is properly included under the title "electrocardiography." The former is a cognate subject but deals largely with the elucidation of valvular lesions by the registration of sound; the second is a totally different topic, as worthy as electrocardiography of a book to itself. It is certainly inappropriate to sandwich 35 pages of radiology into *Illustrative Electrocardiography*. Nevertheless, all of these subjects are clearly and briefly described, and any student or practitioner who seeks an introduction to some of the instrumental methods employed in cardiology will find much of what he needs in this book.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Aviation Medicine, Its Theory and Application. By K. G. Bergin, M.A., M.D., D.P.H., A.F.R.Ae.S. (Pp. 447. 35s.) Bristol: John Wright. 1949.

Sex in Social Life. Edited by S. Neville-Rolfe, O.B.E. (Pp. 506. 21s.) London: George Allen and Unwin. 1949.

The Epidemiology of Hemolytic Streptococcus. By A. F. Coburn, M.D., and D. C. Young, M.D. (Pp 229. 22s.) London: Baillière, Tindall and Cox. 1949.

The Rhesus Factor. By G. F. Roberts, M.A., M.B.Cantab. 2nd ed. (Pp. 64. 3s. 6d.) London: William Heinemann. 1949.

The Clinical Application of Psychological Tests. By R. Schafer, M.A. (Pp. 346. 30s.) London: George Allen and Unwin. 1949.

Textbook of Histology. By J. F. Nonidez, D.Sc., and W. F. Windle, Ph.D., Sc.D. (Pp. 456. 40s. 6d.) London: McGraw-Hill Book Co. 1949.

The Fundamentals of Pulmonary Tuberculosis and its Complications. Edited by E. W. Hayes, M.D. (Pp. 480. 50s.) Oxford: Blackwell Scientific Publications. 1949.

POLIOMYELITIS PRECAUTIONS

We do not know if there will be a major epidemic of poliomyelitis this autumn, but the warning signs are sufficiently grave; and local authorities, hospital management committees, and individual practitioners would be well advised to consider how best to handle the situations which may arise. Attempts to control the spread of poliomyelitis have in the past been singularly disappointing. The apparent ineffectiveness of public health measures must be due at least partly to there being perhaps several hundred cases of abortive infection for every one diagnosed as poliomyelitis. Food in this country is handled so carelessly that the avoidance of infection seems impossible. However, the amount of infection may make a difference, and sensible precautions should be taken without carrying these to tiresome extremes. Parents should realize that they themselves may be carriers of the virus and may infect their own children either by droplets from the mouth or by handling food with contaminated hands. The virus is also found on flies during an epidemic. Clearly the threat of poliomyelitis is an indication for special attention to personal hygiene, and children who are in any way unwell should be put to bed and isolated from others. A patient suspected to have an abortive infection should be kept in bed for one week.[1]

Since little can be done to avoid the virus, the question arises whether any steps can be taken to reduce the risk of the infection, when it occurs, developing into the paralytic form of the disease. In the first place there seems to be little chance of keeping the virus outside the central nervous system, for it is found in the brain experimentally even in abortive cases. Further, though the virus has for long been thought to travel by the nerve axon, Brierley and Field[2] have recently demonstrated a very easy pathway from peripheral nerve to spinal cord by the inter-fibre spaces. This means that some long-established theories will have to be reconsidered.

After a minor and non-specific catarrhal illness, which may be the first indication of infection, the virus seems to lurk in the brain and spinal cord for many days, apparently awaiting an opportunity to attack the nerve cells and cause paralysis. Study of the physiology of the neurone in relation to its vulnerability to virus infection is therefore well worth while: it is a difficult task, but at the present time provides perhaps the most hopeful line of defence. In poliomyelitis the motor cells in the spinal cord are the most vulnerable; and there is good evidence to indicate that motor cells supplying fatigued muscles are, as a result of this fatigue, rendered more vulnerable to the virus. This effect of fatigue may perhaps operate in converting an otherwise abortive case into a paralytic case, but fatigue is probably most dangerous after the pre-paralytic phase, with its meningeal symptoms, has developed.[3] Physical fatigue during this meningeal stage is often disastrous, while even the continuance of normal activity is highly dangerous.

Over-careful advice to make all children rest during an epidemic seems undesirable, but the thoughtful parent can do much to avoid that state of over-fatigue which occurs often during the holiday season, especially when the weather is good. Further, there are theoretical reasons for increasing precautions against fatigue for several days after injury, minor illnesses, sunburn, and surgical operations. Dietary indiscretions, such as eating excessive quantities of fruit, or unnecessary purging may also be harmful. In addition, however, to these mild and easily planned restrictions there should be an absolute rule that children who develop minor illness must go to bed at once, and unnecessary contact with healthy persons should be avoided, particularly when the symptoms are in any way suggestive of those which may occur in the pre-paralytic phase: these include fever, nausea, vertigo, unsteady eyes, retention of urine, pains in the head, neck, back, limbs, chest, or trunk, with perhaps some stiffness of the neck or spine. Ritchie Russell[3] has recently described in this *Journal* some of the many ways in which paralytic poliomyelitis may present.

The doctor seeing a patient who he suspects may be developing the pre-paralytic stage of the disease must often be uncertain about the indications for transfer to hospital. In making his decision he should bear in mind that at this stage the sick child should be kept very quiet, both physically and mentally, with adequate sedation to prevent restlessness and to ensure at least some sleep. In such a case a tiring journey to hospital, followed perhaps by the child crying for its mother, may be harmful, while if isolation precautions are taken in the home and the case is notified a few days' delay is unlikely to cause any otherwise preventable spread of infection. On the other hand, the development of bulbar or respiratory paralysis outside hospital means that the practitioner has a very difficult situation to handle successfully. The need for very early diagnosis by lumbar puncture is not usually a vital matter, but if the differential diagnosis includes the possibility of bacterial meningitis then early lumbar puncture is urgently called for, since specific treatment may be required. It is unnecessary for the doctor to exhaust his patient by testing all muscle groups

[1] *British Medical Journal*, 1947, 2, 141.
[2] *J. Neurol. Neurosurg. Psychiat.*, 1949, 12, 86.
[3] *British Medical Journal*, 1949, 1, 465.

in the acute stage. A few simple tests for each limb and trunk are sufficient to judge whether paralysis is spreading.

Patients with developing poliomyelitis are clearly better cared for in hospital, if it is satisfactorily staffed, but in some cases the doctor and parents may be justified in deciding that the child should remain at home provided precautions are taken to secure isolation and arrangements can be made for transfer to hospital at short notice. If the ability to cough becomes very weak, or swallowing difficult, hospital care is urgently necessary. Bulbar palsy is treated by postural drainage (raising the foot of the bed to make an angle of 30 or more degrees); the use of the respirator must be avoided in these cases if the muscles of respiration are active, since it is liable to suck pharyngeal secretions into the lungs. When respiratory muscles begin to fail there should be a respirator at hand to give the weak muscles a rest and, if necessary, to maintain respiration. If a respirator is not available some other form of artificial respiration must be used temporarily, and of these a resuscitator or lung inflator is the best: the Oxford inflator is excellent for this purpose. The services of an anaesthetist will be found very helpful in such an emergency. Finally it would be wise to overhaul respirators now and to ensure that someone is ready without delay to direct operations when they are required. The National Foundation, 120, Broadway, New York, 5, N.Y., will send to any physician or hospital an excellent booklet on the nursing of patients in respirators.

THE ELDERLY SICK

The fact that the problems of ageing and chronic sickness should have been chosen by Professor A. P. Thomson as the subject for the Lumleian Lectures—published in this and last week's *Journal*—is an indication of their great practical importance at the present time. The Report of the Royal Commission on Population[1] shows that the steady increase in the numbers of the old, both absolute and relative to the rest of the population, has already brought us to the point where there is approximately one person over 65 to six persons of working age, and that in another 25 years the proportion may well be one to four or even less. Clearly such a state of affairs will present society with a difficulty that is potentially disastrous, and it is only sensible to use the present time to determine the best methods of securing for the elderly conditions in which they will be able to live independent and useful lives.

Hitherto medical investigation has been mainly concerned with two aspects of the problem—the rehabilitation of the chronic sick and the physiological processes of ageing. The complete indifference to the state of the aged and chronic sick in the wards of long-stay hospitals has been replaced by a welcome growth of interest in their special needs, and by a realization not only that much can be done to ameliorate their physical distress but also that some of the physical and mental states found in long-stay patients may actually derive from their removal from home to the atmosphere of a chronic ward. Professor Thomson's plea that such individuals should be brought out of their segregation into the common stream of medicine deserves the fullest support. Many of the elderly sick present clinical problems of great interest, and behind these there lies the riddle of the intrinsic nature of the ageing process, which, in spite of some famous assaults in which the intestinal flora and the sex glands were concerned, is still an enigma to the investigator. In addition to the common disabilities of old age there is the sad group of "iatrogenic" disorders resulting from prolonged confinement to bed. It will indeed be some time before the law of diminishing returns begins to apply to the results of skilled clinical research in this field.

It should never be forgotten that the problems of old age are fundamentally domestic, and there is no prospect of their ever being anything else. As recently as 1946 only 1.16% of the population of pensionable age were housed in public assistance institutions. If the great future burden of old age is still to be borne within the family, a better understanding of the sense of family responsibility towards the aged and of the external factors which may facilitate or hinder its operation will be essential. Professor Thomson refers to the prevailing opinion that in general the sense of family unity is weakening, and he suggests that this may be related, at any rate in part, to the fact that there is less reluctance than formerly to call in "public assistance" to solve the problems of family life. This process has probably been hastened by the largely successful attempts of both central and local government departments to banish the stigma of the old Poor Law. Public assistance authorities, for instance, are now "welfare" or "social welfare" authorities—a great improvement in terminology. No doubt the increased numbers of old people in the population will eventually make it necessary to provide some form of assistance to those younger relatives who carry a disproportionate share of the domestic burden of old age, but fortunately both Professor Thomson's findings and the results of Dr. J. H. Sheldon's survey[2] in Wolverhampton show that family loyalty is still a common virtue.

Though the problems of old age are mainly domestic, the number of beds available in hospitals for the treatment of the aged sick is relatively small, and it is of great importance that full use should be made of them. Standards for admission and rate of turnover require careful examination, and Professor Thomson's findings on the social aspects of hospital stay are particularly interesting. No less than one-third of the patients were

[1] Report of the Royal Commission on Population, 1949. London: H.M.S.O. See leading article in the *British Medical Journal*, 1949, 1, 1127.
[2] *The Social Medicine of Old Age*, 1948, London. See leading article in the *British Medical Journal*, 1948, 1, 1142.

admitted to a large infirmary in Birmingham because of some domestic catastrophe, such as the death of a spouse, while the rate of turnover was in part determined by the condition of the home to which the old person would return on discharge. This, again, was affected by the length of the patient's stay in hospital—during the first three months after their admission 71% of the males and 51% of the females have a home to return to, whereas after a stay of four years only 24% of the males and 13% of the females are in this fortunate position. Clearly the mere fact of admission to hospital has undesirable consequences in some cases, and Professor Thomson's findings support the results of the experiment carried out by Brooke at St. Helier's Hospital, Carshalton, to which old people are admitted only if they come within a few sharply limited categories. By the provision of suitable transport and other means every effort is made to provide out-patient treatment for the elderly sick.

Elsewhere in this issue Dr. John Pemberton and Miss Joan Smith report the results of a study of elderly male patients discharged from hospital. They discuss the type of social service which elderly men who are partially disabled by chronic illness require. The most important reason why patients admitted to medical wards did not return to work was because the illnesses from which they suffered were chronic or progressive, and their course could not in most cases be reversed or arrested by admission to hospital. At a recent conference (reported on page 330) on the community care of old people Dr. C. A. Boucher emphasized the necessity for co-operation between the general practitioner, the hospital specialist, and the medical officer of health. It is certain that in the future a medical service for the aged will require to break down the rigid distinctions between hospital and home treatment and between medical and social care.

TREATMENT OF PETIT MAL

Petit mal is difficult to treat: little success has been obtained with the hydantoinates, phenobarbitone only occasionally reduces the number of attacks, while the older remedies—the bromides, belladonna, and borax—are of value in very few cases. A minority of patients are helped by amphetamine, caffeine, or a ketogenic diet, but until recently no form of therapy has been consistently effective. In 1945 Lennox[1] introduced a synthetic product—3,5,5-trimethyloxazolidine-2,4-dione—usually known as "tridione," which has a specific effect in reducing the frequency of petit mal, and in 1947 he reported on its use in 166 patients.[2] He found that 83% of them had improved, and attacks had stopped completely in 31%. Others have since confirmed its value, and in this number of the *Journal* Dr. C. W. M. Whitty and Dr. F. C. Haward report small series of patients with petit mal in whom the drug has been of value. In the former's 46 patients the attacks ceased or there was great improvement in 31 and some improvement in 10 others.

The best results with tridione have been obtained in patients with typical wave-and-spike complexes in their electroencephalographic records, but in some of Whitty's successful cases this E.E.G. abnormality was not present. Lennox divided petit mal into three varieties: true petit mal, in which there is a lapse of consciousness for 5–30 seconds, the patient usually remaining immobile but occasionally having rhythmic jerking or twitching movements of the eyelids, head, and arms; myoclonic attacks, in which single contractions of flexor muscles of the arms occur without impairment of consciousness; and akinetic attacks, in which there is sudden loss of postural control with nodding of the head and, at times, falling and loss of consciousness. It is in these three varieties of attack, especially when the E.E.G. shows characteristic changes, that the best results are obtained with tridione. The drug has no effect in reducing the frequency of major epileptic attacks, and some patients even have an increased number of major attacks when tridione is being administered. When major attacks and petit mal are occurring in the same patient phenobarbitone or hydantoinate has to be given in addition. An unusual feature of treatment with tridione is that in many cases administration can be stopped suddenly without causing an increase in the number of attacks. This does not happen invariably, however, and Whitty found that in two of his patients the attacks increased in frequency when tridione was stopped, and decreased again when they were put back on the drug.

Unfortunately tridione has disadvantages: the commonest toxic symptom is an unusual type of photophobia in which objects appear to shimmer and which is usually called the "glare phenomenon." This appears to be related to the dose employed and can often be stopped by reducing the dose. Lennox noted this side effect in 31% of his patients. Skin rashes may also occur: acne-like papules, the most usual form of rash, are unbecoming rather than dangerous, but at times a rash similar to that of measles may develop, and Lennox advises stopping the drug if this occurs. One fatal case of exfoliative dermatitis apparently due to tridione has been reported.[3] The most serious toxic effect is on the blood-forming organs. This appears to be due to individual susceptibility, as is the case with other drugs, such as amidopyrine or thiouracil, and not to be related directly to the dosage employed. Lennox reported one

fatal case of aplastic anaemia and stated that he had heard of three other fatal cases in the United States. There are published records of two deaths from agranulocytosis[4,5] and two from aplastic anaemia.[6,7] Finally a nephrotic syndrome has been observed during administration of tridione and attributed to the drug.[8,9]

Because of these rare toxic effects tridione should not be used indiscriminately, but should be reserved for cases of petit mal; if possible an E.E.G. record should be made before it is prescribed. It is preferable to find out first whether the petit mal can be controlled by the safer but less commonly effective remedies. If these fail and if the attacks are frequent, then treatment with tridione should be begun. The patient must be kept under regular medical observation while he is taking the drug. A white-cell count and differential count should be performed at monthly intervals, and if the granular cells fall below 1,600 per c.mm. tridione administration should be stopped. Complete reliance cannot be placed on regular cell counts to give warning of agranulocytosis, for it may develop suddenly, and careful watch must be kept for symptoms such as sudden lassitude, pyrexia, sore throat, or stomatitis; if these appear the drug must be stopped and a white-cell and differential count done immediately. As Lennox[10] puts it, "Like any potent weapon of offence, tridione can cause grave harm if not handled with respect and conscientious care, but this would be a poor reason for not using it."

A DISPUTE ENDED

The local authority associations have at last agreed to meet representatives of the medical profession to negotiate new scales of remuneration and conditions of service for public health medical officers.[1] The B.M.A.'s proposals for the new terms were submitted to the Ministry of Health in July, 1948, but in spite of repeated requests the local authorities would not consent to open negotiations on them. In January of this year, therefore, the Council decided that if negotiations through approved Whitley machinery were not begun by the end of February advertisements from local authorities would not be accepted by the *British Medical Journal* unless the salaries offered conformed with those in the Association's proposed scales. The local authorities continued to refuse negotiation, and for the last five months advertisements have not been accepted by this or by other medical journals unless they fulfilled those conditions.

The local authorities' delay has caused inconvenience and hardship to men and women in the Public Health Service; with very few exceptions they have followed the B.M.A.'s advice in refusing to accept appointments which were the subject of an "Important Notice." They are to be congratulated on the fortitude with which they have stood loyally by their colleagues. Only one advertisement in conformity with the Association's proposals has been published in the *Journal* during this period—from Merthyr Tydfil.

[1] See *Supplement*, p. 73.

The last obstacle to the formation of a medical functional council in the Whitley machinery has now been removed. It was not possible to set one up until the local authorities agreed to co-operate, since they must be represented on the management side as employers of practitioners in the Public Health Service. It was also questionable at one time whether the Whitley machinery would be of much value to the profession if it was not backed by the right to go to arbitration. Though the absolute right has not been granted, the consultants obtained satisfactory assurances from the Ministry that, "save in exceptional circumstances, and after the conciliation machinery of Whitley has been exhausted, issues on remuneration remaining in dispute will go either to arbitration or for inquiry and report by a committee." Because of this promise and other assurances the Joint Committee and the Central Consultants and Specialists Committee advised hospital staffs to sign permanent contracts. On July 28 the General Medical Services Committee met and decided that these assurances appeared to safeguard the rights of general practitioners in the Service, and the chairman of the committee has written to Sir Lionel Whitby thanking him "for the magnificent work which you have put in not only for consultants but for general practitioners as well."

Though the Minister has not conceded all that the profession wished in order to ensure that disputes go to arbitration if they cannot be resolved through Whitley machinery, he has gone a good way to meet our requirements and allayed much anxiety. The outcome of these disputes reveals plainly what has so often been said—that when the profession stands together in a just cause it obtains satisfaction. It only remains now to set up the Functional Medical Council and to bring before it, as occasion demands, outstanding points of difference between the medical profession, or any part of it, and the employers' side.

ANATOMY OF THE BRONCHIAL TREE

The anatomy of the bronchial tree used to be a neglected subject, but the last ten years have seen this deficiency corrected and a number of good descriptions have appeared. Recognition of the importance of the broncho-pulmonary segment as a unit has led to advances in knowledge of the natural history, pathology, diagnosis, and treatment of many lung diseases. Drs. J. Hardie-Neil and W. Gilmour, of Auckland, have carried out long and painstaking work on this subject, and an authoritative article by them appeared in this *Journal* in 1939.[1] In a more recent paper[2] they present in greater detail the results of their study of a subject which is of much importance and about which other authors have written little—the comparative anatomy of the bronchial tree and the application of the knowledge acquired to the investigation of the human bronchial tree. In this issue of the *Journal* we publish a summary of the research work undertaken by these authors. The clear exposition of the otherwise confusing arrangement of the subapical bronchi of the lower lobes can be cited as a practical result of their comprehensive anatomical studies,

[1] Hardie-Neil, J., Gilmour, W., and Gwynne, F. J., *British Medical Journal*, 1939, 1, 495.
[2] —— ——, *N. Z. med. J.*, 1946, 45, 20.

which have been carried out on eleven different mammalian species.

Hardie-Neil and Gilmour's nomenclature has also been followed by other authors and has served as a basis for modified nomenclatures. The term "apical segment of the lower lobe" is, for instance, more satisfactory than the term "dorsal lobe." Subapical follows quite naturally from this, in contrast to the ill-begotten and quite unacceptable term "subdorsal," which they criticize strongly. On the other hand, their adherence to a classification which includes four divisions to the right upper-lobe bronchus will not have much support; it is now generally agreed that this lobe contains only three chief broncho-pulmonary segments. The specimens and diagrams they use or borrow from other authors to sustain their claim cannot be interpreted convincingly in the way they suggest. Moreover, in their earlier paper they quote Brock[3] incorrectly when they state that he describes the lateral division of the pectoral or anterior bronchus as the most common site for lung abscess in the upper lobe. According to Brock the most common site is the subapical or postero-lateral segment, and either its lateral or posterior division may be affected, or both together.

These differences of description serve to emphasize that the time is fully ripe for the adoption of a nomenclature that would be, ideally, accepted internationally. A committee in France[4] has recently agreed on a nomenclature, but this certainly is one that would not be accepted in most other countries. It is to be hoped that an attempt will be made to obtain international agreement on a working nomenclature for the anatomy of the bronchial tree.

TUBERCULOSIS IN SCOTLAND

During the present century there has been a great reduction in the tuberculosis mortality rate, and at the same time living conditions generally have improved. The relationship between cause and effect is generally accepted. Disturbances in the life of the people may alter the trend of death rates, and in both of the world wars an increase in tuberculosis mortality occurred. In England and Wales the crude death rate per million from respiratory tuberculosis rose from 989 in 1913 to 1,323 in 1918. In the last war the change was not so great, and the rate rose from 516 in 1938 to 602 in 1941 and then commenced to fall. After the 1914–18 war the fall in tuberculosis mortality was retarded in several areas, but the figures available made a direct explanation of this phenomenon impossible. This slowing down was most pronounced in those towns and areas where social and economic conditions were least satisfactory.

The trend of the death rate in Scotland and in England and Wales has differed during the past few years. In England and Wales the death rate from respiratory tuberculosis has fallen steadily from 557 per million in 1943 to 473 in 1947, while in Scotland the rate fell from 647 in 1941 to 627 in 1945 and then rose in 1946 to 658 and remained practically constant at this level for the next two years. As Mr. Walter Elliot points out in a paper appearing in the opening pages of this issue, a convincing explanation for this rise cannot be found. Paradoxically the economic social factor does not appear to be the important one. The nutritional state of the community, which is probably the most important single factor in determining tuberculosis morbidity and mortality, does not differ between the two countries in these days of food rationing. Housing, another important influence on the prevalence of the disease, has deteriorated more in England, because of the greater damage done by bombing. McKinlay[1] has shown that overcrowding does not explain the different trend of pulmonary tuberculosis in Scotland, and economic factors can hardly be held responsible, since the rise in mortality has occurred during a period of full employment.

The increase in mortality in Scotland has been greater among females than among males. The percentage ratio of the actual deaths in 1946–7 to the expected deaths, calculated from the 1937–9 figures, was 119 for men and 132 for women. All age groups shared in the rise in mortality, though it is among the younger people, particularly those aged 15–25 and, to a lesser extent, school-children, that the adverse change has been greatest. Over Scotland as a whole the mortality follows the usual pattern, rising in the more industrialized areas. Glasgow, with a very high rate and about one-fifth of the total population, takes a large share in the responsibility for the unfavourable trend of the Scottish figures.

The rise in mortality may be due to several causes, and from the figures available for analysis it does not seem likely that these can be positively identified. Mr. Elliot's suggestion that Polish migration in the early days of the war may have introduced a more active strain of infection is interesting but difficult to prove. On a similar line of reasoning the high rate for Glasgow might be explained by the fact that many of the population of the city are of Irish extraction. Susceptibility to tuberculosis is high in Ireland: in 1947 the death rate was 124 in Eire and 79 in Scotland. Some have attempted to explain the proportionate increase in tuberculosis among the younger people by finding fault with their way of living—too many late nights spent dancing or in cinemas, careless eating habits, and a neglect of a proper balance between exercise and rest.

Tuberculosis notifications have risen steadily in Scotland, and in 1948 they were twice the pre-war figure. Comparisons of notifications are not very satisfactory, owing to changes that have been introduced in recent years. By mass radiography minimal lesions are discovered that would have gone completely undetected a few years earlier. Notifications are merely the cases which are discovered, and the number may be only loosely related to the true incidence—the relationship in any area depending upon the carefulness of the local practitioners. Thus the notifications of tuberculosis in England and Wales dropped by 2,000 in 1939 due to the effect of war on medical and administrative procedure.

THE M.R.C.P.

The Comitia of the Royal College of Physicians last week received a report of a committee which had been set up "to consider whether the examination for the M.R.C.P. as regulated and conducted in the past can meet the needs of the future, and to make recommendations." The recommendations were accepted by the Comitia and therefore now become the official policy of the College for the

next two years, when the M.R.C.P. examination will once more be reviewed. The outstanding conclusion of the committee is that "membership of the College should signify a knowledge of general medicine that justifies further training as a consultant, and the examination should therefore be a test in general medicine, on a level higher than that required for qualification." From this follows the conclusion that the examination "should be taken early in training, normally about two years after qualification." The College report recognizes that the M.R.C.P. is widely regarded as the hallmark of the specialist, but also notes that the teaching hospitals more and more demand the M.R.C.P. as the qualification for the post of registrar or chief assistant. It considers that no examination can satisfy both these criteria and that a choice must be made between them.

The choice is admittedly difficult, but the decision of the College is one the consequences of which it does not seem to have thought out to the end. Until now the M.R.C.P. has been looked upon as a qualification conferring specialist status. Obviously the man who has passed the M.R.C.P. has regarded this as the first and important step to establishing his career of a specialist or consultant. It is the beginning and not the end of experience in this field of medicine. When the College states that membership "should signify a knowledge of general medicine that justifies further training as a consultant" the question must be asked, What further training is to be considered necessary, and who is to decide at the end of such training that the possessor of the M.R.C.P. is or is not "a failed specialist"? The answer may be that so far as the College of Physicians is concerned this will be recognized by election to the Fellowship; but many men have practised and are practising as specialists and consultants who have not had this distinction conferred upon them. By its decision the College has altered the status of the M.R.C.P., and this alteration may well be resented by those who have passed the examination on the widely held assumption that its possession was a recognized entry into the ranks of consultants and specialists. Not only does the College decision appear to lower the status of the M.R.C.P., but it may well have the unfortunate effect of lowering the standard of the examination. In fact the two would seem to be inseparable.

The committee considered whether the M.R.C.P. should not be preceded by a primary examination in anatomy and physiology, or any other subjects. It did not, apparently, consider the possibility of holding a primary examination which would qualify successful candidates to enter a final examination the passing of which would clearly define the status of the candidate as a consultant or specialist. The method adopted by the Royal College of Surgeons appears to be more rational and fair, and it may be hoped that when the M.R.C.P. is reviewed in two years' time the College will consider the possibility of holding, instead of the M.R.C.P., a primary examination, possibly in conjunction with the Royal College of Surgeons, as a preliminary to a final examination for the F.R.C.P., say four or five years after qualification. Its present decision is simply a recognition of the fact that very large numbers of young men and women are exhausting themselves and their examiners to obtain a diploma which will enable them to avoid going into general practice. It is no solution to the problem of how a man should be trained and recognized as a consultant or specialist in medicine.

DOMICILIARY MIDWIFERY

The Ministry of Health has issued a statement on the Domiciliary Midwifery Service which, it is advised by the Central Health Services Council, should be given the widest possible publicity. The statement is printed in this week's *Supplement*. The Ministry considers that in England and Wales there is misunderstanding about the nature of the medical services available for the mother who is confined in her own home. The misunderstanding, apparently, is the belief among general practitioners and the public that the doctor accepts full responsibility for antenatal care, labour, and the lying-in period. "This was certainly not the intention; it was not intended in any way to diminish the importance of either the antenatal clinics or the midwives by the introduction of the Maternity Medical Services." The statement points out that the general practitioner, the midwife, the antenatal clinic, the pathologist, and the hospital and specialist services all have a part to play as members of a team. The Ministry appears to go out of its way to stress the value of the service of the midwife and the antenatal clinic. It observes, it is true, that the general practitioner may assume full responsibility for the conduct of the case, but adds that "it is the hope of the Minister that in domiciliary midwifery the midwife will continue to be regarded as a normal attendant, supported by the antenatal clinic during the pregnancy and working in co-operation with the general practitioner. . . ."

In its comment on the report of the Working Party on Midwives the B.M.A. Council[1] criticized it as speaking of the midwife as a practitioner of *normal* midwifery. It criticized also the feeling of competition which was tending to grow up between general practitioners and midwives. The present statement by the Ministry would seem to have the same undesirable effect, even though this may not have been intended. It is obvious that the general practitioner who practises obstetrics must have a large experience of the normal if he is to be able to deal satisfactorily with the abnormal. In its proposals for a General Medical Service for the Nation, published in 1938, the B.M.A. stressed the need in a maternity service for continuous medical supervision by a general practitioner. It considered that an efficient maternity service should include among other things: "(1) antenatal care by, or under the responsibility of, a medical practitioner chosen by the patient throughout pregnancy in every case; (2) attendance in every case by a certified midwife during the antenatal period, labour, and the puerperal period; (3) attendance by the practitioner chosen by the patient during pregnancy, labour, and the puerperal period, when as a result of antenatal examination the practitioner has declared his personal attendance to be necessary, or when his attendance is requested by the midwife." These recommendations are as sound to-day as they were eleven years ago, and it is hoped that in the National Health Service a real effort will be made to see that they are carried out. The present statement of the Ministry of Health is not encouraging.

HEALTH REGULATIONS FOR AIR TRAVEL (III)

BY

R. H. BARRETT, M.R.C.S., D.P.H., D.T.M.&H.

Medical Officer, Ministry of Health

The attention of the travelling public and of practitioners has often been drawn to the number of inoculations and vaccinations that are obligatory on the intending traveller, particularly if he intends proceeding abroad by air. During the period since 1946 the position described in the first article in this series (*British Medical Journal*, 1947, 2, 741) has become more stable, as was indicated by Kyle in the table appended to the second article (*British Medical Journal*, 1948, 2, 1115). This increase in stability has occurred despite the setback caused by the cholera epidemic in Egypt in 1947, an event which precipitated certain health authorities into adopting quarantine measures that had not been invoked since the Middle Ages. The closing of frontiers and the threat of the use of firearms to prevent the unauthorized entry of persons from an infected or supposedly infected area were examples of a fashion in quarantine which might properly have been left in the textbooks of medical history. Nevertheless, the international outlook as regards quarantine has steadily improved, with a corresponding reduction in the delays and frustrations.

It may therefore be of interest to practitioners and others to know that this particular aspect of international co-operation is being actively pursued by the World Health Organization, which has recently taken over the duties previously carried out in this field by the Office International d'Hygiène Publique in Paris. In October, 1948, an Expert Committee on International Epidemiology and Quarantine met in Geneva and considered amongst other matters a revision of the International Maritime and Aerial Sanitary Conventions, which are to be replaced in the future by WHO Sanitary Regulations. It was very encouraging to note the more liberal attitude adopted by the committee towards quarantine restrictions in the light of the advances made by modern methods in disease control.

In the proposed "principles" on which the WHO Regulations for air travel will be based the following recommendations were made; they are of particular interest:

1. *Plague and Typhus Inoculations.*—These inoculations will not be required of travellers by the new regulations. It was considered by the committee that the use of new insecticides and rodenticides now available should be the most effective method of dealing with outbreaks of these diseases.

2. *Cholera Inoculation.*—This inoculation will not ordinarily be required of travellers; but it will be permissible for individual Governments to require it of passengers coming from local areas infected with cholera.

3. *Transit Passengers.*—Air passengers in transit through foreign airports will not be subjected to any sanitary measures in force for that locality—e.g., compulsory inoculations or vaccinations—provided that they are not suffering from an infectious disease and that they do not leave the precincts of the airport. A passenger will not be considered to have left the airport if he is conveyed to another airport in the same vicinity under the supervision of the health authority.

4. *Immunization of Travellers.*—The committee's views on the subject of immunization of travellers as a quarantine measure are worth quoting at length:

> "The committee noted that there had developed since the last war a widespread tendency on the part of health administrations to require from travellers certificates of immunization, irrespective of the value of such immunizations for the protection of the countries reached by the travellers or for that of the travellers themselves.
>
> "The committee was aware of the many disadvantages inherent in the compulsory production of immunization certificates, and considered that the serious obstruction to free and rapid travel caused by such requirement was out of all proportion to the protection likely to be afforded to the country of arrival."

5. *The Personal Declaration of Health.*—This document was compulsory for air travellers in the 1944 Sanitary Convention for Aerial Navigation, but its use under the WHO Regulations will be optional at the discretion of individual Governments.

Summary

In the future, therefore, it seems that the statutory immunizations likely to be required of travellers, apart from those required for personal protection—e.g., T.A.B.—will be confined to vaccination against smallpox and inoculation against yellow fever, with anti-cholera inoculation as an occasional measure. Practitioners with practical experience of these diseases in epidemic form will probably not quarrel with this decision. But the traveller will no doubt impatiently await the day when world epidemiological conditions will render even these measures unnecessary.

The Expert Committee reflected this feeling in the first of the "principles" upon which the new regulations will be based when it was agreed that "WHO Regulations would be needed until the true object of international epidemic control—the eradication of the pestilential diseases—had been achieved."

INTERNATIONAL CONGRESS OF OTOLARYNGOLOGY

EDINBURGH VISIT

A discussion on "Otogenous Thrombophlebitis and its Complications" was held in conjunction with the Scottish Otological and Laryngological Society in the Department of Surgery, University of Edinburgh, on Monday, July 25. Dr. G. Ewart Martin, president of the Scottish society, was in the chair.

In the absence through illness of Professor Norman M. Dott (Edinburgh), who was to have led the discussion, the opening paper was delivered by Dr. BERGER THOMAS (Edinburgh). Dr. Thomas dealt with the complications of thrombophlebitis which might be met in cases exhibiting a resistant strain of organism. He first described aseptic thrombosis of the lateral sinus, which may produce a subacute external hydrocephalus (the post-otitic hydrocephalus of Symonds). This could be demonstrated by ventriculograms. Treatment consisted in the intravenous administration of hypertonic saline solution and the control of cerebrospinal fluid pressure by a lumbar puncture. Where no improvement occurred a subtemporal decompression, with a simple stellate opening in the dura, was advocated.

Aseptic thrombosis of the cerebral branches of the lateral sinus was often silent in onset, the patient first complaining of loss of vision or seizures due to cerebral damage following thrombosis of the veins. Ventriculograms showed localized cerebral involvement with ventricular shift and displacement of the third ventricle. In these cases antibiotics were given, and the cerebrospinal pressure controlled as already described. A bone-flap decompression might be required.

In connexion with the septic complications of thrombophlebitis of the lateral sinus, Dr. Thomas referred to Gradenigo's syndrome, which he thought was seen less commonly since the introduction of antibiotics, and which he regarded not as an apical petrositis from direct spread of the infection but as a thrombophlebitis of the petrosal sinus. Subdural empyema, on the other hand, was more commonly encountered now, particularly after frontal sinusitis. Cerebral and cerebellar abscesses were now considered to be due to a thrombophlebitic process rather than a direct spread of infection. Dr. Thomas showed that tension within the abscess interfered with the penetration of penicillin. When the abscess was drained surgically, penicillin could then be recovered from the pus.

Dr. A. BROWNLIE SMITH (Edinburgh) contrasted his experiences of lateral sinus thrombosis before and after the introduction of antibiotics. Although diagnosis was often easy before the advent of penicillin, many cases presented extreme difficulty, and complications were frequent. Since penicillin became available the difficulty of diagnosis had increased but the serious consequences of thrombosis had diminished. Of the 29 cases of lateral sinus thrombophlebitis in his series, 22 occurred before antibiotics were introduced, and of these 14 were complications of acute otitis media. There were seven deaths (32%) in this series. One was due to the anaesthetic, and six occurred from undue delay in operating, either because the case was referred too late or because the condition was not

suspected until the patient had been some days in hospital. Of the seven remaining cases, all were associated with chronic otitis media and five were in children under the age of 11 years. No deaths occurred in this series, and in no patient receiving penicillin was the jugular vein ligated. It would appear that lateral sinus thrombosis as a complication of acute otitis media was disappearing, or if it occurred the condition responded to antibiotic treatment and remained undiagnosed. The cardinal features—rigors, positive blood culture, raised cerebrospinal fluid pressure, and a positive Queckenstedt test—were not now seen, and the temperature chart was the only certain guide to the possibility of thrombophlebitis. An unexplained temperature in the face of penicillin treatment for acute otitis media was, in Dr. Smith's opinion, an indication for urgent operation.

OLD PEOPLE AND THE COMMUNITY

A two-day conference was held recently at the Royal College of Nursing on the community care of old people. Those who took part included representatives of the nursing service of the L.C.C., the Women's Voluntary Services, the Civilian Welfare Department of the British Red Cross Society, the Public Health section of the Royal College of Nursing, and the National Council of Social Service.

Mr. ARTHUR BLENKINSOP, M.P., Parliamentary Secretary to the Ministry of Health, said that most local authorities were now providing accommodation for old people on their new housing estates of a much more attractive kind than had hitherto been available. He hoped it would be possible to provide a certain number of hostels also where services could be rendered to the occupants. Old people often became permanent bed cases in hospital when, for their own benefit and that of others, they ought to be taking their place again in the community.

Dr. KENNETH COWAN, county medical officer of health for Essex, spoke on the care of the chronic sick in hospitals in relation to shortage of beds and lack of nursing staff. Where treatment by rehabilitation and physiotherapy had been given there had been a remarkable increase in the bed turnover. He instanced the position in Cornwall where, by the use of adequate rehabilitation and medical treatment for the chronic sick in the institutions of the county, the available bed accommodation had been increased by 50%. Part-time nursing staff had been used to good purpose in some areas, particularly in Gloucestershire. He pleaded for suitable holiday homes and hostels in the country where aged people who were living with their relatives could be taken for short periods, so relieving the strain at home and perhaps enabling the old people to continue their home life for a much longer time. For organized voluntary endeavour in the care of the aged he suggested a national organization which would institute measures for the care of old people in their homes and formulate a policy which could be carried out locally.

Dr. C. A. BOUCHER, medical officer of the Ministry of Health, said that the problem of the aged was really a problem of social medicine—that is to say, of medical science applied to groups of people. He begged that these people should not be isolated as a race apart. Their relatives, friends, and neighbours would then be relieved from all responsibility, which would be unfortunate. In spite of the brilliant work of experienced specialists and enthusiastic doctors in geriatric units, much more could be achieved if there was adequate help at an earlier stage before chronicity developed. The geriatrician had already shown what could be done; he must now show how much more could be prevented. The present overloading of hospital beds was a confession of failure of preventive measures. The fantastic position had been reached whereby an old person who required skilled hospital treatment had to wait a long while for it. The result was that his illness became well advanced, it required a much longer period for treatment and rehabilitation, and in the end the patient had often to be retained in the institution because his family circumstances had altered and there was no home to which to send him. Four thousand old people were killed every year in accidents in their homes. If they were made aware of these dangers and how preventable they were, this heavy fatality list would be lightened and hospital beds would not be filled with fractured femurs and the like. He praised St. Helier Hospital, Carshalton, where they had a geriatric liaison committee with representatives of Surrey County Council, the Hospital Management Committee, the Local Executive Council, and the National Assistance Board. Another notable effort was the Bermondsey Mission, which was run by three general practitioners. The mission had a ward of 25 beds for old people, and a geriatric specialist from a near-by hospital visited once a week and was available on call. There was need, said Dr. Boucher, for a "triangular" system. At the apex was the family doctor, who knew the old person and his background. At one of the bases was the hospital specialist, the geriatrician, and at the other the medical officer of health, through whom the local authority and voluntary association services should be made available. These services included home helps.

No resolutions were formulated, but it was stated that the ideas put forward at the conference would serve as a guide for local action in the months ahead.

COLONIAL MEDICAL RESEARCH

TRIAL OF NEW DRUGS IN THE TROPICS

The Colonial Research Council is responsible for research schemes in many fields—agriculture, forestry, demography, social science, engineering, and a dozen others. Research in medicine, undertaken by the Medical Research Committee, of which Sir Edward Mellanby is chairman, is one of the most important of its interests; of the last annual grants, amounting to £1,652,169, medical research schemes took more than 10%. Many of the other investigations have medical aspects, such as the work on insecticides and the search for plants of possible medicinal value.

The annual report of the Council[1] contains a list of about 150 new or supplementary projects which have been approved for grants during the year under review. They range from an investigation into the technique of parboiled rice to a study of the properties of antisera for identification of blood found in mosquitoes and other insects; from the bionomics and distribution of ornithodorus ticks in relation to relapsing fever to the establishment of the East African Bureau of Medicine; from psychological research in Northern Rhodesia to an investigation into the suitability of the roller mill for milling millets and sorghum, this latter as part of nutrition research in West Africa; from the setting up of a medical research library in Fiji to the study of hot-climate physiology in Nigeria; from an investigation of salt-water mosquitoes to studies in African witchcraft.

The Medical Research Committee had some eight projects in hand last year in Africa and Malaya, and during the year started two new ones. The first was an investigation on Bancroftian filariasis and onchocerciasis in East Africa, and the other was a study of loasis (infestation of *Loa-loa*, a genus of filarial roundworm) in the Cameroons. The whole subject of filariasis is being extensively investigated in East Africa, and Mwanga, in Uganda, has been selected as the headquarters of the Colonial Office team for this work. Research on schistosomiasis is already being undertaken independently in Egypt and in Southern Rhodesia, and it is not considered necessary to begin work on this subject in the colonial territories at present. From Egypt it is reported that marked clinical improvement has been obtained by the use of "miracil D," but complete sterilization does not appear to have been obtained as a rule in the Egyptian patients. Moreover, the drug has been found irritating to the gastro-intestinal mucosa, which contraindicates its general use in Egypt. In Southern Rhodesia the drug works more favourably—for some reason the dweller by the Zambesi withstands its irritant action better than the dweller by the Nile.

Prophylactic Value of Proguanil

Work on malaria has been continued in Malaya, East Africa, and North Borneo. In Malaya extensive trials have been made

[1] *Colonial Research 1948-49*. Cmd. 7739. London: H.M. Stationery Office. 2s. 6d. net.

to establish the prophylactic value of proguanil and mepacrine. Among the labour forces on the plantations in an endemic area the high suppressive value of proguanil in *falciparum* and *vivax* malaria has been confirmed. The disappearance of parasitaemia when proguanil was given was found to be more rapid than with mepacrine in cases of *falciparum* malaria, though the duration of the fever was somewhat longer. The exact comparative value of these two drugs seems as yet undetermined. The most suitable methods of using proguanil, with its effective gametocidal action, have been worked out for both prophylaxis and treatment. The prophylactic value of the drug is said to be high, but the clinical response to treatment slow. It has been found that the duration of the fever is shortened and relapse prevented when the ten-day course of proguanil is supplemented, on the first day of treatment only, by mepacrine or quinine, and the trial of this reinforced method is recommended. Chloroquine has also been tried out with a view to its probable practical value in rural areas.

Work on nutrition has been continued in the Gambia and elsewhere, chiefly on the prevalent types of anaemia and the extent to which these conditions are dependent on malnutrition and on zymotic disease. A study of the digestive function in conditions of malnutrition is being undertaken in Uganda by the Medical Research Council. Protein deficiency is shown to be common in the Gambia. Other investigations include research in tick-borne relapsing fever in Kenya. The Virus Institutes in Nigeria and Uganda have been primarily concerned with a study of the epidemiology of yellow fever, and the work in Uganda has shown that there exists in Africa an epidemiological type of yellow fever which is analogous to the jungle yellow fever of South America. It is now thought that the permanent reservoir of virus which exists in the animals and mosquitoes of the forest is the ultimate source of the yellow fever of urban communities.

Chloramphenicol in Scrub Typhus

A section of the medical report concerns the work of a research unit in Malaya which is making a long-term study of the natural history of scrub typhus, a condition which took a heavy toll of the Allied forces during the Japanese war. An investigation has been made by an American unit on the value of the new antibiotic, chloramphenicol, in this condition and in typhoid fever. An explosive outbreak of scrub typhus occurred on an estate near Kuala Lumpur soon after the investigation began, and during the next 10 weeks 40 proved cases were treated with the drug without failure. Some of them were treated as late as the eighth or ninth day of the disease, although in untreated cases death may occur from the twelfth day onwards. Up to now about 90 cases have been treated successfully. A small amount of the drug prepared by chemical synthesis became available to the workers at Kuala Lumpur and was used in treating two Gurkha soldiers infected during jungle warfare against bandits. They were given the synthetic drug on the fifth and sixth days of fever, and in both cases the temperature reached normal within 48 hours. The toxicity disappeared and convalescence was uneventful. In typhoid fever the improvement of the general condition and the diminution in toxicity usually began within 24 hours. One curious circumstance is that chloramphenicol has been found effective against gonorrhoeal urethritis, and a recent preliminary communication records the successful treatment of 32 cases. The importance of this finding, which is thought by venereologists to open up a fruitful field of investigation, lies in the fact that the drug is given orally. The successful large-scale synthesis of an effective non-toxic antibiotic has obviously wide implications. It is hoped that the number of diseases affected by this class of drug will be increased, and that reduced costs, approximating perhaps to those of the sulphonamides, will gradually free chloramphenicol and other antibiotics from the restrictions imposed by expensive fermentation methods of preparation.

The question of undertaking trials in Africa with B.C.G. vaccine has been considered further. In French and Belgian African territories this vaccine is already being tried out. The Medical Research Committee considers that trials should be undertaken in a selected area with a stable population and a known incidence of tuberculosis, and the committee is making suitable arrangements. Climate physiology is another long-continuing study. One experiment mentioned is that small doses of pituitrin have been given to a group of eight African students, and those who had high sweat-rates were found to have them lowered after injection, while those with low sweat-rates had the opposite experience. In other words, without pituitrin there was a great difference between the sweat-rates of the two sub-groups, but after pituitrin there was no difference.

The tsetse fly has been a major preoccupation of a number of colonial investigators this year. The important reports on trypanosomiasis in Eastern and Western Africa and on the Anchau rural development scheme have been the subject of notice in these columns. They were followed by the introduction of "antrycide" for the treatment of trypanosomiasis in cattle, about which the Colonial Office report expresses the hope that the experiments now in progress will establish the prophylactic value of this drug and extend its practical application. A sum of £15,800 has been allocated for a three-year research on the effects of antrycide injections on cattle in East Africa. An account is given of the trials in Uganda with D.D.T. and B.H.C. smokes. It has been confirmed that these substances are lethal to tsetse flies, but the application apparently still presents difficulties. The malaria eradication experiments in Mauritius and Cyprus are described, as well as the control measures in Uganda, Swaziland, and Malaya.

It is stated that the shortages of scientific personnel, labour, building materials, and equipment are being slowly overcome, and proposals are to be submitted to Parliament for the amendment of the Acts under which colonial development and welfare research is administered, to enable the yearly disbursement to be increased.

SCIENTIFIC FILM ASSOCIATION

MEDICAL FILMS

A meeting called by the Medical Committee of the Scientific Film Association was held recently at the Royal College of Obstetricians and Gynaecologists.

Mr. MALCOLM DONALDSON in his introductory remarks said that the object of the meeting was to discuss the best way to encourage the use of films and film strips in teaching. At present there was no central medical film library for teaching purposes. There were very few medical films and more would have to be made. This could perhaps best be done by the senior teachers of any particular subject forming a committee and, after deciding exactly what points it was necessary to illustrate, writing a script for a film to be produced by a professional film artist. Although everyone had his own methods of teaching, it was uneconomical for each man to make his own film. The fundamental points which an undergraduate had to learn were common to all teaching schools. It was after qualification that points of difference in technique should be taught.

Sir KENNETH GOADBY, the chairman of the Medical Committee, said that the Scientific Film Association had been in existence for five or six years. The association had as its aim the general diffusion of knowledge concerning the making, use, and advantages of scientific films in all branches of education. The Medical Committee was handicapped by want of funds. It had published, in conjunction with the Royal Society of Medicine, a catalogue of medical films, and had corresponded with the deans of medical schools in the hope of stimulating interest in the use of films as an aid to teaching. The real value of the medical film was in presenting the salient points which could not adequately be demonstrated by lantern slides or by word of mouth.

Films were then shown illustrating normal labour, the use of Kielland's forceps, and breech delivery. *Girl Grows Up* was a film intended to explain menstruation to girls aged 12 to 14, and a film on the care of premature infants came from the Rotunda Hospital. In the discussion after each film, among many who took part were Sir WILLIAM GILLIATT, Dame LOUISE MCILROY, and Mr. LESLIE WILLIAMS. The production of these films was of a high standard, but there was outspoken criticism of the obstetrical technique illustrated in some of them.

INTERNATIONAL CONFERENCE ON AUDIOLOGY

The second International Conference on Audiology was held in London on July 15 and 16, at the Royal Society of Medicine, under the presidency of Professor Gunnar Holmgren (Sweden). The Conference was attended by otologists, physicists, and others interested in the various aspects of audiology. Fifteen countries were represented.

The delegates were welcomed on behalf of the Royal Society of Medicine by Mr. Scott Stevenson, president of the Section of Otology. On the first day a review was given by the secretary, Professor Eelco Huizinga (Holland) of work already done. Papers were read by Professor Maurice Sourdille (France), Dr. E. P. Fowler, jun. (U.S.A.), Professor E. Luscher (Switzerland), and Dr. Harvey Fletcher (U.S.A.). The second day was occupied by a discussion on the work in audiology carried out in England by the Ministry of Health, the Medical Research Council, and others. An introductory address was given by Sir Wilson Jameson, Chief Medical Officer of the Ministry of Health, and other speakers included Dr. C. S. Hallpike, Medical Research Council; Dr. W. G. Radley, G.P.O. Research Station; Mr. R. S. Dadson, National Physical Laboratory; Dr. T. S. Littler, Department of Education of the Deaf, Manchester University; Mr. Michael Reed, Ministry of Health; Dr. E. A. Underwood, Ministry of Education; Miss Edith Whetnall, Royal National Throat, Nose, and Ear Hospital; Mr. R. Scott Stevenson, Metropolitan Ear, Nose, and Throat Hospital; Professor Sir Henry Cohen, Medical Research Council; Mr. Leslie Wilkins, the Social Survey; and Mr. Terence Cawthorne, Medical Research Council. At the end of the meeting it was announced that the present secretary was retiring and that his place would be taken by Mr. Terence Cawthorne (England).

Reports of Societies

HAEMODYNAMICS OF PREGNANCY

At a meeting of the Edinburgh Obstetrical Society on May 11, with the president, Dr. E. C. FAHMY, in the chair, Professor R. J. KELLAR presented a symposium on the "Haemodynamics of Pregnancy." His critical review of the subject was supplemented by four short papers.

Dr. HILARY HAMILTON gave a brief description of previous experimental work and then analysed the changes in cardiac output during normal pregnancy in 68 women. Output was determined by the Cournand technique of right heart catheterization. Experimental work now in progress at the Simpson Memorial Maternity Pavilion was concerned with the cardiac output in cases of toxaemia all showing some degree of hypertension. Preliminary results in 44 cases showed that they fell into fairly distinct groups. Pregnant patients with "fixed" essential hypertension (10 cases) showed no alteration in cardiac output from the curve found in normal pregnancy. In 6 cases of "fixed" essential hypertension with superimposed pre-eclampsia a rise in cardiac output was noted. There was also an increase in cardiac output in 11 cases of "labile" hypertension.

Varying results were observed in 17 cases of pre-eclampsia; 13 had a mild or marked increase in output, and this usually exceeded the increase seen in the two hypertensive groups; in 4 cases the cardiac output was within the normal limits for the duration of pregnancy. The changes in cardiac output in the cases of pre-eclampsia did not appear to bear any clear-cut relationship to the clinical severity of the toxaemia. No explanation of these results could be put forward at the present time, but it was hoped that future work would help to clarify the situation.

Blood Volume and Blood Flow

Dr. RACHEL WHITE contributed two short papers, one on blood volume in pregnancy and the other on limb volumes in pregnancy. In the first paper she outlined the method used and the results obtained in the investigation of 10 normal non-pregnant women, 56 women at various stages of normal pregnancy, and 10 women in the first week of the puerperium. She showed that the increase in blood volume during pregnancy was approximately 23%—a result comparable with those of previous investigators. This increase occurred mainly during the second half of pregnancy and was maintained for the first seven days of the puerperium. She also gave a preliminary survey of the results of investigations now being carried out during pregnancies complicated by hypertension and pre-eclampsia. From these results it appeared that the blood volume in cases of hypertension ("labile" and "fixed") was comparable with that in normal pregnancy, while in cases of pre-eclampsia it was lower than normal.

The second paper was concerned with a study of the limb volumes of 15 patients during the second half of pregnancy. She described the method, which was based on the principle of water displacement, and said that records were kept at 2–4-weekly intervals during the pregnancy and at seven days and six weeks after delivery. Of the 15 cases, four had a normal pregnancy with a variation of 0.5 to 3.8% in limb volumes; 7 cases developed a mild to moderate degree of toxaemia with an increase of at least 6% in all their limb volumes, a 6 to 7% increase appearing to coincide with the presence of "pitting" oedema. The remaining 4 cases showed an increase of up to 9% in at least one limb volume with no other manifestation of toxaemia. She also showed that the increase in volume during pregnancy appeared to be more marked in the hand used less frequently—i.e., the left hand in right-handed patients.

Dr. CATHERINE BURT presented a preliminary report on blood flow and finger temperatures in 20 pregnant patients (8 normal, 7 pre-eclamptic, and 5 hypertensive) compared with those in a group of non-pregnant controls. Records of resting forearm blood flow made in the later weeks of pregnancy showed an increased flow in normal pregnant patients in comparison with non-pregnant women. A greater increase was found in pregnant patients with pre-eclamptic toxaemia or hypertension; in these cases the average resting forearm blood flow was twice that of the control group. In all the pregnant patients a fall in the average forearm blood flow occurred following delivery, but the figure remained above that of the non-pregnant group for the first few weeks of the puerperium. During reflex vasodilatation tests forearm blood flow was more variable and showed a greater average rise in pregnant than in non-pregnant patients, this increase being most evident in patients with pre-eclamptic toxaemia.

At an environmental temperature of 17° C. non-pregnant women and women in the first trimester of pregnancy showed peripheral vasoconstriction as evidenced by a low resting blood flow in the hand; as pregnancy advanced the hand blood flow showed a gradual rise up to the time of delivery. A state of cutaneous vasodilatation, as shown by a resting finger temperature of over 30° C., was found in 19 out of 20 cases in the later weeks of pregnancy and in all 17 tested in the first eight weeks of the puerperium. In non-pregnant volunteers exposed to the same environmental temperature (15.25° C.–22.5° C.) the average finger temperature was 24.7° C. This preliminary work indicated a tendency to muscular and cutaneous vasodilatation in the upper limbs during the later months of pregnancy.

On June 17 and 18 the Fever Group of the Society of Medical Officers of Health held a meeting at Seacroft Hospital, Leeds, by invitation of the president of the Group, Dr. E. C. Benn. On June 17 Dr. D. C. Liddle read a paper on the Steven-Johnson syndrome, and Dr. H. J. Parish, Dr. K. J. Randall, and Miss M. Barr contributed a symposium on "Immunity in Early Life." In the afternoon Dr. Leese, Professor J. W. McLeod, and Dr. P. T. Boyle gave a clinical, bacteriological, and pathological review of a series of patients with tuberculous meningitis treated with streptomycin. On June 18 Dr. Hugh Parry read a paper on "The Fate of Infants with Gastro-Enteritis Receiving Intravenous Plasma," and Dr. C. W. Dixon gave an account of an outbreak of meningococcal meningitis in New Zealand.

Correspondence

Ankylosing Spondylitis

SIR,—I have been very interested to read the letters of Drs. F. Dudley Hart and H. F. West (April 9, p. 633) in reply to Dr. C. B. Heald's communication (March 26, p. 546). Dr. West rather takes Dr. Heald to task for being over-enthusiastic about ankylosing spondylitis. We in New Zealand recently had the pleasure of hearing Dr. Heald when he was asked to lecture on rheumatism by the New Zealand Government. In connexion with ankylosing spondylitis one would agree that he showed enthusiasm, but is it not better to show enthusiasm than adopt an attitude of *laisser-faire* in such an important and, in many cases, such a crippling disease? Dr. H. F. West has looked up a great many references which are not available in this country, and rather tends to belittle the crippling effect of ankylosing spondylitis and also the benefits of *x*-ray therapy. Two cases I have seen recently illustrate that the disease can be crippling and does respond to *x*-ray therapy.

The first was a woman aged 33 who complained in the first place of pain in the neck and back and a little later stiffness in the left shoulder. A course of gold injections had been advised and given without any relief, and her condition was becoming worse. Her right arm could not be raised above the level of the shoulder and the pain and stiffness in the back had spread to the lumbar region. A diagnosis of ankylosing spondylitis was made from radiographs. An interesting point in this case was that while waiting for *x*-ray therapy an injection of 1 ml. "prostigmin" was given. The patient almost immediately felt ill, became collapsed, and vomiting set in. The antidote to this, 1/100 gr. (0.65 mg.) of atropine, was given, and the reaction gradually subsided. Within 24 hours there was marked improvement in the movement of the right arm, which could be raised above the head. In spite of the reaction, the patient begged for a second injection. This time atropine was given prior to ½ ml. of prostigmin—even so the patient had a milder reaction. Any further requests for injection were refused. Three courses of deep *x*-ray therapy to the dorsal and lumbar spine and sacro-iliac joints were given. In addition, after consulting with Dr. John Mennell, manipulation was given to the cervical dorsal and lumbar vertebrae and the costo-vertebral articulations from time to time. This has produced freedom of movement in these areas. In addition breathing, which was becoming increasingly difficult, has been very much relieved. This patient now has no pain, is bright and happy, and can manage her own housework and cooking. There is permanent loss of rotation in the dorsal vertebrae and limited lateral movement in the lumbar region. In spite of this she is very grateful for the marked improvement in her movements, general health, and her freedom from pain. Before I saw her she was spending most of her time in bed, and the future outlook was not at all good.

The second case, a young man of 20, had been suffering from "rheumatism" for four years, with pain in the back and limbs. General wasting of muscles was present, the joints of both limbs were swollen and painful, and he was in continual pain. For the last 14 months he had been confined to bed almost continuously. Gold injections, penicillin, physiotherapy, and polyvalent streptococcal vaccine had all been tried without effect. Dr. C. B. Heald was called in consultation and diagnosed the case as one of ankylosing spondylitis. Radiographs showed quite definitely involvement of the sacro-iliac joints. *X*-ray therapy was ordered with very satisfactory results. Two years later this patient reported that he had had several courses of *x*-ray therapy—not only to the spine, but also to the joints of the upper and lower limbs. Apart from the fact that there is a rather general stiffness of joints, he can go about his teaching duties at a preparatory school, and, most important of all, he is free from pain.

In both the preceding cases it can be stated quite definitely that ankylosing spondylitis was having a crippling effect, and following *x*-ray treatment there has been a very marked improvement in their condition and they have again become useful citizens.—I am, etc.,

Christchurch, New Zealand. W. GORDON RICH.

Treatment of Angina with Thiouracil

SIR,—All those who have tried to investigate the value of thiouracil in the treatment of angina pectoris will agree with your annotation (June 4, p. 997) that "it is time a large series of cases was treated under scientifically controlled conditions." But it seems unlikely that both these requirements can be satisfied. Evans and Hoyle[1] have drawn attention to the main difficulty, which is the inherent variability of angina. They conclude that in addition to adequate scientific control the type of case selected for study must be clearly defined if the results are to be reliable.

The investigation described below, though not significant on its own, may contribute a little to the subject when read in conjunction with other reports. An attempt was made to select for study only those cases which were as nearly "stable" as possible. The criteria were as follows:

1. All had unequivocal angina of effort, with pain as their worst symptom. Its site, type, relation to exertion, and quick relief by rest or glyceryl trinitrate were definite. If a neurosis became obvious and predominant during the investigation the patient was excluded from the series.
2. No patient had dyspnoea as a prominent factor limiting exertion.
3. No patient had any other physical disability limiting exertion or lowering pain threshold.
4. No patient had a haemoglobin below 90%.
5. No patient had evidence of myocardial infarction in the six months immediately preceding the start of the investigation.
6. No patient had hypertension above 170/110 mm. Hg or evidence of valvular disease, paroxysmal disturbances of cardiac rhythm, or cardiac failure.
7. No patient had clinical or serological evidence of syphilis, or clinical evidence of thyrotoxicosis, diabetes, or adrenal disturbance.
8. All were under the age of 65 years.
9. All were at least of average intelligence.

Out of over 80 patients attending the hospital with angina only 19 fulfilled the above criteria, but during subsequent weeks 11 of these had to be excluded from the series for the following reasons: dyspnoea found to be prominent factor limiting exertion, 3; neurosis became overt, 3; failed to attend, 2, no attacks during the summer, 1; developed pernicious anaemia, 1; developed status anginosus, 1. This last patient had thiouracil for one week only. It was stopped because his attacks became more frequent. A week later he developed status anginosus. The eight patients who remained were all men between the ages of 49 and 64 years. Three had had previous myocardial infarctions.

The initial examination of the patients included a detailed history, full clinical examination, fluoroscopy, and limb and unipolar chest lead electrocardiograms. During the first two weeks the variability of the angina was observed, and base-line white-cell counts and blood-cholesterol determinations were made. Four patients were then given 0.2 g. of thiouracil three times a day (Group A), and the remaining four one lactose tablet three times a day (Group B). No patient knew what tablets he was having. Each patient was urged to continue his normal routine of life.

Observations were made on the pulse rate, blood pressure, weight, glyceryl trinitrate requirements, walking distance on level ground, and blood-cholesterol levels for periods ranging from 19 to 36 weeks. Thiouracil was stopped when there was evidence of myxoedema. In two patients (Cases 1 and 2) who had shown only a slight response to the initial dose the dose was increased to 1.0 g. daily after 17 and 19 weeks respectively. Progress was assessed by comparison of the glyceryl trinitrate requirements and a detailed history of the pain at the beginning and at the end of the investigation. The table shows the progress of each patient.

It will be seen that three out of four patients in the treated group were improved, whereas only one patient in the control group was slightly improved. In those who were benefited improvement occurred gradually during the third and fourth months of treatment, and it is interesting that the improvement was more marked in the substernal than in the peripheral component of the pain. The patient in Group A who did not improve was the one who had had a previous myocardial infarction. Serial blood-cholesterol levels were found not to

correspond to thiouracil dosage or to the clinical response to treatment. There were wide variations in level in both groups of patients. One patient (Case 3) developed florid myxoedema, with a cholesterol level lower than at the start of the

Patient	Age	Previous Infarction	Weeks of Observation	Result	Weekly Glyceryl Trinitrate Requirements		Maximum Weight Change in Kg.	Remarks
					Before	During		
				Group A				
1	50	No	34	Improved	Nil	Nil	−4	Individual attacks less severe. Substernal pain almost completely disappeared. Pain in left wrist no longer distressing. Distance increased from two miles on level ground to five miles including hills
2	63	No	33	Improved	20–30	12	−20	Substernal pain disappeared; only pain in throat remained. Cold weather no longer a precipitating factor. Able to manage stairs, previously impossible. Myxoedema after 29 weeks. B.M.R. −15%
3	63	2 yrs. before	32	No change	25–30	28	+35	Myxoedema after 19 weeks. B.M.R. −20%
4	56	No	22	Improved	10–20	Nil	Nil	Chest pain disappeared; only left shoulder and elbow pain remained. Meals, emotion, and cold weather no longer precipitating factors. Able to run 100 yards for bus without pain, whereas previously any hurrying brought on pain
				Group B				
5	64	5 yrs. before	36	No change	30–35	Same	+20	No change
6	63	No	19	No change	10–20	Same	−4	No change
7	59	1 yr. before	36	Slightly improved	90–100	Same	+7	Very doubtful improvement judged by detailed history of pain
8	49	No	22	No change	20	Same	+29	No change

investigation. It is hoped that these results once again confirm the difficulty of assessing the results of any form of treatment in angina pectoris.

Dr. Evan Jones, Dr. F. T. G. Prunty, and Dr. Raymond Daley have kindly agreed to the publication of this letter. I am very grateful to them for the special investigations and for their interest, advice, and criticism.

—I am, etc.,

Uffculme, Devon. D. W. R. LYLE.

Tuberculosis in Industry

SIR,—Drs. Alice Stewart and J. P. W. Hughes and their colleagues (May 28, p. 926) showed that a tenfold increase in the size of boot and shoe factories was associated with a twofold increase in the number of persons "infected with tuberculosis." Their paper appears to have caused some surprise and criticism (Dr. Stephen Hall, June 11, p. 1049). It is, of course, true that it is only by the routine use of the tuberculin test that recently infected persons can be detected: it is, however, of interest that statistics collected by Bang as long ago as 1896 showed that a tenfold increase in the size of herds of cattle was associated with an approximate doubling of the incidence of tuberculosis as judged by the tuberculin test.[1] This is true even when small herds in which there were no tuberculous cattle were excluded. Almost the same trend is obtained by classifying results of tuberculin tests on 364,286 cattle in Great Britain according to the size of the herd.[1]

Dr. Hall has suggested that infection is inevitable, and the important thing is to study why only some people develop clinical tuberculosis. It appears to the present writer that no attitude could more stultify the main effort which should be made to control tuberculosis. It is true that every effort should be made to increase resistance (including the use of B.C.G.), but it was pointed out at the recent Commonwealth and Empire Health and Tuberculosis Conference that tuberculosis is still a serious problem in New Zealand, where the standard of nutrition is excellent. All the work on the control of tuberculosis in cattle indicates that it is the degree of exposure to infection which is important and that effective control of the disease is achieved only when every effort is made to prevent the spread of infection. As pointed out by Dr. S. Roodhouse Gloyne (July 2, p. 31), the work of Drs. Stewart and Hughes does indicate that in man the degree of exposure to infection has an important effect on the number of "recently infected" individuals.

The question of whether one should concentrate on breeding and feeding cattle with "sound bodies and perfect mucous membranes" in order to eliminate tuberculosis was being discussed in 1901 when McFadyean[2] wrote: "The man whose sense of proportion is not hopelessly defective will attach only minor importance to such considerations, and will concentrate his efforts against the one great cause of the disease—the operation of contagion. When that has been successfully grappled with predisposition becomes of no account. . . ." Subsequent events have proved him to be correct.

It is, of course, true that it is much more difficult to control tuberculosis in man than cattle, but Myers[3] and his colleagues have created areas in which no child of primary-school age reacts to tuberculin, and on the island of Bornholm Olsen[4] has reported that communities have been made free from infection with tubercle bacilli. Both these workers have consistently emphasized the importance of treating tuberculosis as an infectious disease and concentrating special efforts on the prevention of spread.—I am, etc.,

Fibrocystic Disease of the Pancreas

SIR,—After reading Dr. W. J. Matheson's interesting article (July 23, p. 206) I am prompted to give a short account of a case of fibrocystic disease of the pancreas in an infant which I was fortunate enough to diagnose during life.

The patient, a female infant 8 weeks of age, was a first-born child; delivery was normal but the birth was said to be 5 weeks premature. Her birth weight was 5 lb. 8 oz. (2.5 kg.). Since birth she had failed to gain weight and was stated to have had continuous diarrhoea and occasional vomiting. She had been given several different proprietary foods, none of which had been continued for very long. On examination she was a marasmic infant weighing 5 lb. 2 oz. (2.3 kg.). She had signs of bronchitis; her stools were yellow, loose, copious, and both offensive and frequent. She vomited occasionally, but apart from this took her feeds well and appeared always hungry. In spite of correction of her feeds she did not gain weight and remained marasmic. The Wassermann reaction was negative, and bacteriological examination of stools, and chest radiographs, etc., did not reveal any abnormality. Blood count showed definite anaemia: haemoglobin 67%, R.B.C.s 3,250,000.

AN ADVANCE IN PENICILLIN THERAPY

'AVLOPROCIL'

PROCAINE PENICILLIN 'G' OILY INJECTION

(with 2% Aluminium Stearate)

'Avloprocil' contains the procaine salt of Crystalline Penicillin in oily suspension and offers important advantages to both doctor and patient:—

Therapeutic blood levels of penicillin maintained for 36-48 hours or longer

Effective penicillin therapy achieved with a single daily injection

Administration comparatively free from irritation and pain

10 c.c. *vials* (300,000 *units of penicillin per c.c.*) *Singly and in boxes of* 5

foundation of trouble-free weaning

The popularity of Farex is based on sound results . . . practical success as an infant weaning food over many years. Here is a food that provides a sensible balance of protein, fat and carbohydrate; a sufficiency of mineral salts; and adequate vitamin nutrition —all factors of first importance in the infant diet. *Three* cereals are blended in Farex with extra iron, calcium and vitamin D, forming a bland smooth food ideally suited to the young digestion. Indeed, Farex mixed with milk and sugar can be given to babies just as soon as they turn the scales at 15 lbs., even if this happens as early as the fourth month. Farex is ready cooked and is therefore very quickly prepared. It is unflavoured, too, which means that it can be mixed with strained vegetables, bone broth, fruit juices and so on. And, incidentally, Farex is very economical.*

VARICOSE VEINS and ULCERS

Elastocrepe is Elastoplast cloth without the adhesive spread. It, therefore, has the unique properties of *stretch* and *regain* which are associated with Elastoplast.

Elastocrepe provides comfortable and adequate support and compression for its particular purpose, and is superior in every way to the ordinary crepe bandage. When soiled it may be washed—washing *renews* its elasticity.

Elastocrepe TRADE MARK

SMOOTH SURFACE CREPE BANDAGE

Made in England by T. J. SMITH & NEPHEW LTD., HULL

In view of these negative findings—accompanied by the following four facts: (1) continued failure to gain weight in spite of an adequate calorie intake; (2) persistent, loose, bulky, offensive, and frequent motions; (3) feeds eagerly taken by the infant; (4) severe bronchitis not responding to chemotherapy—a tentative diagnosis of fibrocystic disease of the pancreas was made. However, before further investigations could be carried out the child developed bronchopneumonia and died. Necropsy revealed a well-marked bilateral bronchopneumonia and some fatty degeneration of the liver. Histological examination of the pancreas showed typical fibrocystic disease.

I agree with Dr. Matheson that this condition is probably more common than one would be led to believe by published reports, and I feel with him that this diagnosis should be considered when infants presenting the above four criteria are encountered.—I am, etc.,

Stoke-on-Trent. JAMES HINGSTON.

Essential Hypertension in Pregnancy

SIR,—The report (July 16, p. 148) of my statement at a discussion on this subject at the twelfth British Congress of Obstetrics and Gynaecology is so brief that I should be grateful if you would kindly allow me to amplify it. My main thesis was that functional vascular spasm due to sympathetic overactivity was the primary factor in the early stages of hypertension, that it resulted locally in renal cortical ischaemia, and that a humoral substance or substances produced within the kidney in consequence of the anoxia or hypoxia passed into the general circulation to produce effects throughout the body as a whole.

My belief in the occurrence of such nervously intermediated functional vascular spasm within the kidney is strengthened by the evidence provided by Solymoss (*Lancet*, 1949, 1, 957) and also by the results obtained by Dr. Robert A. Hingson, of Johns Hopkins Hospital, in his treatment of eclamptic patients by means of controlled spinal analgesia. Dr. Hingson has recently lectured in Oxford and London on his technique and the effects of its application in such cases, and the gist of his findings is that the interruption of reflex nervous pathways at the renal spinal level can in a vast majority of cases produce rapid relief from the gross symptoms and signs (including oliguria and anuria) of eclampsia.—I am, etc.,

London, W.1. JOHN SOPHIAN.

Reactions to Intravenous Sclerotics

SIR,—In the last quarter of 1948 you published a short series of letters under the above heading. I should like to report a further case of acute allergic reaction following the use of "ethamolin," and to pose one or two queries therefrom.

The patient, a woman of 58, with bilateral gross varices, was subjected to juxtafemoral ligation and resection of the left internal saphenous vein, together with retrograde injection of 10 ml. P2G (2% phenol in glycerin), in January of this year. Following this she attended on ten occasions, at weekly intervals, for injections of ethamolin, receiving a total of 37 ml. (averaging 4 ml. per visit). On the first occasion she received the customary 0.5-ml. test dose, to which she showed no reaction. The visits were uneventful, except that at the fifth she fainted, but recovered immediately.

In April a similar operative procedure was performed on the right leg, and following this she attended on three occasions for injection of ethamolin into the remaining varices, receiving a total of 8.5 ml. At the fourth visit she received 4 ml. (three injections of 1.5, 1.5, and 1 ml. respectively) and left for home shortly afterwards. About ten minutes later, while approaching her house, the skin of her back and shoulders began to itch, and her breathing, she noticed, was becoming "wheezy." She returned to the clinic, where I saw her twenty minutes after the injection.

On examination, she was faintly cyanosed and was clearly suffering from a mild attack of asthma. There were patches of urticarial erythema and weals all over her body, being most marked over the left upper arm. There was no reaction at the site of the recent injections. A total of 10 minims (0.6 ml.) of 1:1,000 adrenaline was administered. The itching ceased within five minutes, and the skin reaction had disappeared within half an hour. On questioning, she stated that she usually suffered from asthma in the winter months, but not in the summer unless she had a cold. She added that a cold had been "coming on" for the past two days. She had never experienced a similar skin reaction before. She returned home and continued her normal work. When seen one week later she stated that she had remained well, with no recurrence of her skin reaction. She was still a little wheezy, however.

Perhaps the most important lesson to be learnt is that even ethamolin can seemingly give rise to a generalized systemic allergic reaction. Patients should wait a little while before returning home, and adrenaline should always be to hand. The obvious conclusion to be drawn is that the patient has been slowly sensitized to ethamolin during the past six months, but I must confess to being not entirely convinced by this thesis. While it would be an extremely bold man who would administer a further dose of ethamolin to this patient (a man, I hasten to add, far bolder than I), could it not be that the patient was in a "trigger" state, and that an injection of saline at that particular time might have produced a similar allergic reaction? How are we going to explain the case reported by Dr. C. E. Taylor (Sept. 18, 1948, p. 573) in which, following an allergic reaction to sodium morrhuate, the substitution of sodium salicylate produced an exactly similar result? What reason can be advanced for the fact that allergic reactions are occasionally reported following a test dose of 0.5 ml. of a sclerotic never before administered to the patient?

It would help if we could learn of any case where a sclerotic which had previously given rise to a reaction had inadvertently been administered on a further occasion, and with what result. Perhaps your correspondence columns, Sir, may help to provide the answer.—I am, etc.,

London, E.8. S. M. RIVLIN.

Sir William Osler Centenary

SIR,—The memory of "the greatest physician of all time" was fittingly honoured by the Osler Club celebrations at the Royal College of Surgeons on July 12, followed by the pilgrimage to Oxford on July 16 (concluding with the visit to the famous almshouse and church at Ewelme). It is, perhaps, not generally known that the Osler exhibition at the Radcliffe Camera in Oxford will be open to the public for some months. One wishes that it could be visited by every doctor (including those overseas) who is on the *Medical Register*. A trip to that beautiful "city of dreaming spires" is always a delight, and, to a medical man, the added inspiration from visiting the Osler exhibition will be more than worth the expenditure of time and effort.

How many doctors realize that Osler's world-famous textbook, *The Principles and Practice of Medicine*, has appeared in a Chinese edition? Or that during his lifetime Osler had the following qualifications and distinctions conferred upon him: LL.D. (Aberdeen, Edinburgh, Liverpool, Leeds, Yale, Harvard, McGill, Toronto, Johns Hopkins); F.R.C.P.London, 1883; M. 1878; L. 1873; M.D.McGill, 1872; M.D.Oxon., 1905; M.D.(Hon.) Oslo; Sc.D.(Cantab.); D.Sc.(Hon.) (McGill, London, Leeds, Berlin, Vienna, Trinity College, Dublin); D.C.L.(Durham); F.R.S., etc.? In addition to which he was, among other things, president of the Bibliographical Society and, later, president of the Classical Association. His publications numbered over 1,500. Certainly an astonishing record.

Recently the French have made a film of Laennec, the originator of the stethoscope. Is it too much to hope that the English-speaking world will make a film of the life of "The Great Physician"?—I am, etc.,

London, W.5. L. CARLYLE LYON.

Histamine Headache

SIR,—The report on the treatment of histamine headache by Dr. M. Eszenyi-Halasy (June 25, p. 1121) was both instructive and timely. Should it arouse the profession from a somewhat lethargic attitude towards such ailments it will certainly have served a useful purpose.

For some reason both general practitioners and specialists seem to fight shy of making a serious attempt to treat sufferers from "migrainous" headaches, be these associated with menstruation or allergy, or inducible by histamine. To tell a patient to "go to bed with an aspirin" is as much a confession of failure on the part of the physician as it is useless to the

patient, who may be incapacitated for as long as three days every two or three weeks. Ergotamine tartrate, though useful in some cases, requires to be injected at the very start of the headache, a procedure often quite impossible.

Dr. Eszenyi-Halasy has shown that histamine headaches can be cured in a significant percentage of cases by giving increasing doses of histamine by injection, thus producing a tissue tolerance. I have had comparably good results in cases which give a positive intradermal histamine reaction by the oral administration of gradually increasing doses of "prostigmin" bromide as advocated by Pelner and Aibel.[1] This is a simple procedure and has the added advantage of not inducing headache or requiring injection.

So far as true migraine is concerned, it seems a pity that, as one person in five hundred is a sufferer, greater use is not made of the anterior-pituitary-like hormone[2,3] or even, in obstinate cases, urea.[4] I have personally treated over 150 cases in the past six years, and relief from this crippling complaint has been achieved in over 50% of patients.

Surely it is time more consideration was given by the profession to therapies which can alleviate one of the commoner, even though not lethal, complaints suffered by mankind.—I am, etc.,

London, W.1. NEVIL LEYTON.

Treatment of Rheumatism with Cortisone

SIR,—The paper by Hench and his colleagues[1] on the beneficial therapeutic effect of 17-hydroxy-11-dehydrocorticosterone (Kendall's compound E) and of adrenocorticotropin (ACTH) in rheumatoid arthritis was undoubtedly of remarkable significance. In a recent paper cases of rheumatic fever are also presented.[2] The practical significance of the advantages mentioned in this second report—the rapid improvement in the anaemia, the atrioventricular interval, and the sedimentation rate—seems to be not of the highest importance. The cardiac involvement was unaltered in all cases. There is no definite practical advantage over bed-rest with salicylate therapy.

Before these compounds come into wide use it is as well to note communications of Ingle[3] and Conn and his colleagues.[4] According to them, both of the compounds are capable of producing at least a diabetes-like picture in animals and in human beings. In Hench's cases the doses were large, and the duration of the treatment is long; this merits some attention.—*I am, etc.*,

POINTS FROM LETTERS

Length of Gestation Period

Dr. DORA J. ADAMS CLARK (Spennymoor, Co. Durham) writes: In connexion with the case reported under the heading "A Still Longer Gestation Period" (July 16, p. 181), I have seen to-day a woman in late pregnancy whose last period finished on August 2, 1948. Thus she might be 351 days pregnant.

Sunburn Treated by Antihistamine Drug

Dr. DONNELL DEENY (Lurgan, Co. Armagh) writes: On a recent holiday in the South of France my wife and I suffered a mild attack of sunstroke, with headache, elevation of temperature, reddening of the skin, and great discomfort. Since the liberation in the tissues of histamine causes vascular dilatation and oedema, it seemed reasonable to give an antihistaminic drug ("antistine"), 30 mg. four times daily. We found considerable relief from local irritation. The skin lesions did not proceed to oedema and desquamation so fast or so severely as in other members of our party who did not take the tablets, although the period of exposure to the sun was the same. The sedative effect of the drug was also of help in this painful condition.

Obituary

LAWRENCE JONES, M.S., F.R.C.S.

Mr. Lawrence Jones died on July 11 at the age of 71. He received his medical education at St. George's Hospital and qualified with the Conjoint Diploma in 1900. He took the London degree of M.B. in 1901 and the B.S. with first-class honours, as well as the F.R.C.S., the following year. While serving as surgical registrar at St. George's he took the M.S. in 1904.

His seniors formed a high opinion of his capabilities; he was soon appointed assistant surgeon to the hospital, and lecturer in operative surgery both at the medical school and at the London School of Clinical Medicine. His ability, allied to a singular modesty and charm of manner, had marked him out for success as a consulting surgeon in London, when he was attacked by a very serious illness which necessitated major surgical treatment. He made a satisfactory recovery, but was advised that the strain of consultant practice in London entailed a risk which he ought not to run. He therefore gave up his hospital post and accepted an appointment as chief examining surgeon to the Great Central Railway Company. Here he was able to use his talents to the great advantage of the company's employees for many years until his final retirement a few years ago. He was unmarried.

Dr. Frank Coleman writes: As a colleague and friend of NORMAN GRELLIER, I should like to express my appreciation of his sterling qualities and integrity of character. I knew the Grelliers—Norman and Bernard—whilst they served on the staff of the Royal Dental Hospital for four or five years after the first world war. Apart from Norman Grellier's many interests and distinctions recorded in the obituary notice (June 18, p. 1099), the twin brothers had much in common both in work and play. Flying was one of their mutual accomplishments. Norman and Bernard joined the Cinque Ports Flying Club at Lympne in October, 1933, and early in the following year both took their "A" licences. Norman and his brother had a theoretical and practical knowledge of mechanics which no doubt contributed to their rapid progress and efficiency in aeronautics. From then onwards they joined several flying-clubs in Kent and Sussex and regarded flying as their week-end pastime, although this included aerobatics and other forms of stunt flying. After the last war they became active members of a gliding-club. It was on the evening of Sunday, April 19, 1936, that these brothers had their only accident. Norman was piloting a Gipsy Moth and Bernard was a passenger, when the aircraft stalled at a height of 100 feet and crashed in a field at the top of Hythe Hill, just off the roadway. Both were seriously injured, but on recovery they were back at Lympne and resumed their flying. Incidentally, this accident enabled many of us to distinguish the brothers, as one had been trephined for a fractured skull and the scar of the operation showed. Norman was medical officer to a Grenadier Guards battalion from 1915 until the end of the war, and remained with them for a time at Cologne after the armistice. His brother Bernard served for a similar period as medical officer to a battalion of the Royal Welch Fusiliers. Both were awarded the Military Cross, Norman at Passchendaele and Bernard in the Ypres Sector. The ashes of Norman, carried in a casket, were scattered over the South Downs in a plane piloted by his brother.

Dr. GUY THORNTON BIRKS died at his home in Bedford on June 25 at the age of 71. He was educated at Harrow and King's College, Cambridge, where he took honours in the Natural Science Tripos, and later the degree of M.B., B.Ch., receiving his clinical education at St. Thomas's Hospital. After

holding house appointments there Dr. Birks went to practise in Bedford in 1906, joining the late Mr. W. Gifford Nash. For 30 years he was on the staff of the Bedford County Hospital as honorary physician, and was an energetic and popular honorary secretary to the local Bedford Medical Society for 15 years. He served in the R.A.M.C. in Palestine during the war of 1914–18. To the regret of his colleagues and patients ill-health enforced a too early retirement a few years before his death. Dr. Birks was a good diagnostician and clinician, a wise and kindly adviser, and a loyal colleague, well liked in both lay and professional circles. He was a fine example of the type of medical adviser now unfortunately fast disappearing.—H. D. P.

Dr. A. FLETCHER-JONES died suddenly on July 11 at Chester, while on holiday from his home in Alderney, at the age of 75. He qualified with the L.R.C.P.&S. at Edinburgh in 1897, and shortly afterwards took up an appointment in North China as a medical missionary. *His life in China* was full of adventure. Soon after his marriage he and his wife were driven from their home by the Boxer rebels, and this fate befell them again during the 1911 revolution. For his work in connexion with a plague epidemic the Chinese Government conferred upon him the Order of the Excellent Crop. In 1921 he retired from his missionary work and settled in practice in Alderney, where he held many public appointments. When Alderney was evacuated during the war he took up an appointment as resident medical officer at the Southampton Isolation Hospital and Sanatorium. While Southampton was being subjected to heavy bombing he never considered his own personal safety, and tended the sick and wounded with that care and friendliness which endeared him to patients and staff alike. On the liberation of Alderney he returned and re-established his practice, overcoming great difficulties. He leaves a widow, a married daughter, and four sons, one of whom is a member of the medical profession.

Medico-Legal

PREGNANCY OF 360 DAYS

The Court of Appeal gave judgment on July 22 on the case of a baby stated to have been born after a pregnancy of 360 days. By a majority, Lord Justice Denning dissenting, the Court directed a new trial, and gave leave to both sides to appeal to the House of Lords.[1] The husband's evidence was that he had been serving in Germany, had had home leave from Aug. 7 to 17, 1945, and had been demobilized on Feb. 9, 1946.[2] He had had no access to his wife between those dates, but on Aug. 13, 1946, she had borne a child which weighed 8¼ lb. and was apparently normal in every way.

Lord Justice Bucknill, with Lord Justice Asquith concurring, said that the question was whether it was contrary to the laws of nature that the child, if conceived not later than August, 1945, could be born a normal healthy child 360 days later without any forcing or prolonged labour. The husband had applied for leave to call further evidence. It was proper that he should have an opportunity of calling it.

Lord Justice Denning, dissenting, said that a Judge did not require evidence to prove that in the ordinary course nine months elapsed between the conception and birth of a child. He might take judicial notice of the fact that there might be a margin of a week or two on either side without noticeable effect on the child, but that if the margin became a couple of months either way the result would be apparent on the body of the child. He said that he would have been for allowing the appeal and granting a decree *nisi*.

Under an order made by the Treasury, scientific instrument cases have been exempted from purchase tax.

Medical Notes in Parliament

NURSES (SCOTLAND) BILL

On July 20 the House of Lords went into Committee on the Nurses (Scotland) Bill. Clauses 1 to 6 were agreed to. On Clause 7 (the Mental Nurses Committee) Lord MORRISON moved amendments which he explained were drafting ones. He further explained that the great bulk of the amendments to be moved were drafting or consequential or dealt with minor points on which there was no difference of opinion. The amendments were accepted and Clause 7 as amended was passed. Amendments were also made in Clause 8 (Registration of Nurses Trained Abroad), and the amended Clause was accepted. On Clause 9 (Closing of Part of the *Register*) Lord Morrison moved an amendment which debarred the General Nursing Council from asking for the closure of the principal supplementary parts of the *Register* unless it was satisfied that other means existed enabling the public to identify nurses with special training. He said that what would happen in practice was that when the *Supplementary Registers* were closed the Council would attach an appropriate distinguishing mark in the main *Register* to the names of nurses who had undergone particular forms of training. The amendment corresponded to one made in the English Bill, and it was desirable to have similar provisions because of the statutory reciprocity between the Scottish and English *Registers*.

Lord CLYDESMUIR said the amendment was desirable, and the slight difference in drafting from the English version had been made because in Scotland nurses for mental defectives were entered in a separate supplementary part of the *Register*.

The House agreed to the amendment and Clause 9 as amended was carried. Small amendments were made in Clause 10 (Provisions Relating to the Approval of Training Institutions). Clause 10 was then agreed to as amended and Clauses 11 to 14 were approved. A drafting amendment was made in Clause 15 and this Clause, with Clauses 16 to 18, was agreed. On Clause 19 (Interpretation) Lord MORRISON moved an amendment making clear that references in the Bill to supplementary parts of the *Register* included references to parts which had been set up by rules made in pursuance of the Act of 1919. He said the only statutory supplementary parts were the parts for male nurses, for mental nurses, and for sick children nurses. The parts for nurses for mental defectives and for fever nurses had been set up by rules. The House accepted the amendment and agreed to Clause 19 as amended. Clause 20 was approved. On the first schedule Lord CLYDESMUIR moved to leave out paragraph 3 and to insert:

3. The members of the Council appointed by the Secretary of State shall include—

(*a*) two registered nurses employed in services provided under Part III of the National Health Service (Scotland) Act, 1947, appointed by him after consultation with such persons and bodies as he thinks fit, being persons and bodies having special knowledge and experience of the work of nurses so employed;

(*b*) registered medical practitioners, appointed by him after consultation with such organizations representative of the medical profession as he thinks fit;

(*c*) persons with experience in hospital management, appointed by him after consultation with such persons and bodies having experience in hospital management as he thinks fit; and

(*d*) persons with experience in local government, appointed by him after consultation with such local health authorities, or such organizations representative of local health authorities, as he thinks fit.

He said the amendment was the result of an agreement with the Government. It was to give more precise direction about the type of person to be appointed by the Secretary of State to the General Nursing Council. It would secure that nurses employed by voluntary bodies under contract with local authorities would not be debarred from appointment. It also directed that medical practitioners should be included in the composition of the Council, and it named persons with experience of hospital management and also persons with experience in local government. This would meet the

representations of bodies which had proposals for improving the Bill in this respect.

Lord MORRISON accepted the amendment and the House agreed to it. A further amendment was made and the first schedule as amended was approved. On the second schedule (Regional Nurses Training Committee) drafting amendments were made on the motion of Lord Morrison. An amendment moved by Lord POLWARTH dealing with the qualifications of auditors was withdrawn. The schedule as amended was agreed to. The third schedule (the Mental Nurses Committee) was amended to make it clear that persons appointed to fill casual vacancies must have the qualifications which would have been required had they been elected or appointed in the ordinary way. This schedule and the third schedule were then approved and the Bill was read a third time.

Distribution of Doctors

On July 21 Mr. PLATTS-MILLS reported that in the Borough of Finsbury there was only one doctor to every 3,678 of the population, compared with one for each 2,935 in Islington, and 2,429 in Holborn.

Mr. BEVAN said redistribution of the available supply of doctors in accordance with the best interests of the public must be done gradually. The method of remuneration under the National Health Service, coupled with the powers of the Medical Practices Committee to close over-doctored areas to new entrants, should be sufficient to bring about the desired result.

Hospital Administration

Mr. DONNER on July 21 asked Mr. Bevan if he knew that the Basingstoke hospital service was now responsible to the Winchester Group, which was responsible to the Region, which in turn was responsible to the South-Western Board; that expenses of operation had been increased by this system as well as by the appointment of officials, and that delays due to this centralized control marred the efficiency of the service; and whether he would simplify control.

Mr. BEVAN said if Mr. Donner sent evidence of delays and increased expense he would investigate it, but he was not prepared to consider unsubstantiated statements.

Mr. DONNER said the chairman of the hospital committee had resigned.

Mr. BEVAN said there were 10,000 to 11,000 voluntary workers in the hospital system, but this was the first resignation which the Ministry had received. Mr. Bevan added that the regional hospital board was considering the provision of a new hospital in Basingstoke, but progress must depend on its urgency compared with other calls on the available money and building resources. A new x-ray set would be delivered to Basingstoke hospital shortly.

Attendance at Maternity Clinics

On July 21 Mr. LANGFORD-HOLT inquired to what extent regulations made under the National Health Service Act made it compulsory for expectant mothers to go to a maternity clinic.

Mr. BEVAN replied that he had made no regulations which made it compulsory for expectant mothers to attend clinics. He hoped, however, that they would realize that it was much in their interest to do so.

Televised Operations

Mr. JANNER asked Mr. Bevan whether he was aware that for the first time in medical history delegates to the International Gynaecological Congress saw televised operations; and what precautions were taken to ensure that the patients or their relatives gave their full consent.

Mr. BEVAN replied on July 21 that an operation was televised by land line to a lecture theatre in the medical school to which delegates from the Congress were invited. It was therefore a purely private occasion, and the operation was not "broadcast." This method avoided all the difficulties and possible dangers to the patient of the alternative normally used—i.e., to have groups of spectators in the operating theatre itself.

Typhoid in Kenya

Mr. LONGDEN asked on July 19 for information on the typhoid epidemic in the British Army camp at McKinnon Road, Mombasa, Kenya.

Mr. SHINWELL said he had received a full report on this unfortunate outbreak. A total of 88 cases of typhoid and enteric group fevers had been reported up to July 8, of which 34 were British and 54 African. In addition to the deaths of two British soldiers four African soldiers had died. The outbreak originated among the African troops, but the source of infection could not be definitely stated. The water supply had been thoroughly investigated, and it seemed most unlikely that it was the cause. Everything possible had been done to ensure that the hygiene of the area was fully up to standard and to ensure that all troops and civilian employees were protected by inoculation. A good number of civilians in the area had also been inoculated. The outbreak was now under control, although the possibility of further cases occurring could not be ruled out.

Tuberculosis in the Colonies

When the Colonial Estimates were debated on July 20 Mr. ANTHONY GREENWOOD complained that the Colonial Office Report on Development and Welfare made only four references to tuberculosis in the Colonies. There was little doubt about the high incidence of tuberculosis and the high death rate from it. In Lagos the mortality rate was 128 per 100,000. The Director of Medical Services for Kenya reported that the position in respect of tuberculosis gave rise to anxiety, and that there appeared to be no doubt of its increasing spread. In Tanganyika the tuberculosis mortality rate had doubled in six years. Small dispensaries, mobile units, and trained staffs were most needed.

Dr. HADEN GUEST said visits to West Africa by consultants in obstetrics, tuberculosis, and social and preventive medicine had been of great value, but up to the present sufficient doctors had not been obtained for the Colonies. Doctors did not to-day exist in the required numbers. There was a shortage of general practitioners alike in the United Kingdom and in the Colonies. The medical schools set up in East Africa, West Africa, the West Indies, Singapore, and Hong Kong would not supply any large number of medical officers for eight to ten years. If the Colonies competed in this country for specialists and general duty doctors it would be an error. It would be better to treat the Colonial Medical Service as a branch of the National Health Service in this country. Doctors could be sent to the Colonies for six months or a year. When they returned, other doctors from the National Health Service in this country would take their places. That might also be required in other spheres outside the United Kingdom where doctors were difficult to get. There would not be in the next 50 years the proportion of doctors to population which there was in this country. Dr. Guest thought the system would have to be adopted of employing medical auxiliaries who could carry out medical preventive work under medical direction without themselves being qualified.

Mr. CREECH JONES in his opening remarks had said that the Colonial Service had vacancies for 163 doctors, but Mr. REES WILLIAMS in replying to the debate did not touch on medical questions.

Grading of Venereologists

Sir ERNEST GRAHAM-LITTLE asked Mr. Bevan whether, as by reason of the down-grading of venereologists, the total of accredited specialists would be reduced to a number wholly insufficient to deal with the increasingly anxious problem of venereal disease, he would review the position.

Mr. BEVAN replied on July 22 that boards were reviewing their medical establishments in the light of the needs of the service. He added that it would not be proper for the grading of existing individuals to be influenced by considerations of staffing requirements. He was making inquiries about dissatisfaction among whole-time venereologists in the Liverpool area who found themselves relegated to the category of senior hospital medical officers.

Kenny Treatment

Mr. VIANT asked Mr. Bevan, "in view of the failure of medical science to discover a cure for poliomyelitis," to give an assurance that steps had been taken to provide the Kenny treatment to sufferers from this disease.

Mr. BEVAN replied on July 22 that this method of treatment was well known to specialists in the disease in this and other countries. The use of it in individual cases was a matter of medical discretion. It had not been shown that it would be justifiable to adopt it to the exclusion of other methods used in current medical practice which were no less valuable.

Infectious-disease Certificates

On July 25 Sir ERNEST GRAHAM-LITTLE drew attention to the fact that persons certified by a general practitioner as being unfit for work as a result of being carriers or contacts with one of the more serious infectious diseases were refused sickness benefit, as only a certificate issued by a medical officer of health was accepted. He said this was much resented by general practitioners.

Mr. STEELE replied that this provision had been introduced into the National Insurance (Unemployment and Sickness Benefit) Regulations to give effect to a specific recommendation by the National Insurance Advisory Committee. He had no reason to think it was not working satisfactorily.

Prescribing by Service M.O.s

Mr. NIALL MACPHERSON asked on July 27 why Service doctors at stations in Great Britain and Northern Ireland were not allowed to prescribe for wives and families of Service personnel registered with them on National Health Service forms, so that their patients could obtain necessary medicines from local chemists free of charge instead of having to buy them when they were not available at the station dispensary. Mr. Macpherson suggested that Service doctors at stations in Great Britain and Northern Ireland should be registered as medical practitioners with the appropriate executive council in respect of such patients.

Mr. A. V. ALEXANDER replied that participation of Service medical officers in the National Health Service would not be feasible, since the resulting division of responsibility would be bound to give rise both to administrative and disciplinary difficulties. They could not, therefore, issue prescriptions on National Health Service forms. There was, however, no reason why dependants of Servicemen should have to pay for medicines prescribed by Service doctors, since the Service Departments themselves met the cost if such medicines could not be supplied by a Service dispensary.

X-ray Films.—Mr. BEVAN states that there is a general shortage of x-ray films. He has had to ask hospitals to economize in their use.

Contraceptives.—Mr. CHUTER EDE can hold out no prospect of legislation to prevent the sale of contraceptives from slot machines.

Hospital Transfer.—Mr. BEVAN has informed the Boards concerned that he is unable to agree to the proposed transfer of the South-Western Hospital, Landor Road, S.W.9, to St. Thomas's Hospital.

Closed Areas.—In general Mr. BEVAN will not give permission to exceed the normal maximum in any area where the Medical Practices Committee considers that the number of doctors is adequate. Where a doctor has an assistant he is able to have a larger list.

Confinement in Hospital.—Mr. BEVAN said on July 14 that hospitals and local authorities were being encouraged to give priority for hospital confinement to those who needed it for *medical reasons* or because home circumstances are unsatisfactory.

Spectacles.—Mr. BEVAN said on July 14 that the total demand for spectacles in the United Kingdom in the first six months of 1949 was estimated at 5,000,000 pairs. Production during the same period had been about 3,700,000 pairs and continued to expand rapidly.

Children Electrocuted.—Twenty-three children have been electrocuted in 1948 on live rails, other than those belonging to the London Transport Executive, 11 being killed and 12 injured.

Medical Films.—Mr. BEVAN has arranged for the acquisition of suitable films as they become available, with the object of building up a special medical and nursing section of the Central Film Library.

Duck-egg Poisoning.—Asked about recent incidents of food-poisoning which had been traced to consumption of duck eggs, Mr. BEVAN said it was safest to bake or fry these eggs, or to boil them for at least ten minutes. They should not be preserved in water-glass or eaten uncooked.

Rheumatism Clinics.—In Wales one clinic in charge of a senior hospital medical officer deals exclusively with rheumatism. In addition, treatment is given in the special departments of 23 hospitals and by arrangement at four spas.

Foot-and-mouth Disease.—In co-operation with the French authorities the Ministry of Food has arranged that livestock exported to Britain shall be drawn only from areas which are believed to be free from foot-and-mouth disease and kept segregated from other animals to minimize any risk of importing infected meat

Records of Vaccinations.—There is no statutory requirement for doctors performing vaccinations against smallpox to report them to their local medical officers of health or executive committees, but there are arrangements for doctors taking part in the vaccination service of local health authorities to supply them with records. These authorities make returns accordingly to the Ministry of Health.

Tuberculosis Waiting-list.—About 960 cases are on the waiting-list in South Wales and Monmouthshire of persons suffering from tuberculosis who have been certified as needing institutional treatment. Mr. BLENKINSOP states that the reason for the length of the wait is lack of staff, which Mr. Bevan is doing all he can to remedy.

Universities and Colleges

UNIVERSITY OF EDINBURGH

At a Graduation Ceremonial on July 20 the following medical degrees were *conferred*:

M.D.—E. G. Barnes, [3]A. E Claireaux, J. W. Fraser, [2,4]A. D. Gillanders, D. Gilmour, J. S. Grant, [4]B. Isaacson, [1]Marjory A. Keith, C. K. McDonald, W. A. L. MacFadyen, C. Mackie, [4]A. B. Monro, M. Niazi, A. W. Williams, [2]J. H. Young.

C.M.—[3]A. W. Wilkinson.

Ph.D.—In the Faculty of Medicine: M. M. A. Aal, B.M., B.Ch., Barbara E. Clayton, M.B., Ch.B., Helen N. Duke, M.B., Ch.B., J. A. Loraine, M.B., Ch.B., [4]H. C. W. Stringer, M.B., Ch.B.

M.B., Ch.B.—Mary H. Aitken, J. A. D. Anderson, O Archer, [5]P. G. Aungle, N. E. Awunor-Renner, J. S. Barrett, J. A. Beattie, M. H. Beaubrun, B. Bendkowski, J. S Berkeley, L. H. Berman, W. F. Blair, Dorothy S. Bleakley (née Macdonald), Halina Bobinska, D. H. A. Boyd, J. D. D. Brown, J. H Brown, J B Brown, T. A. Brown, I. A. Cameron, I. H. Cameron, Margaret M. Cameron, J. H. Campbell, M. A. Campbell, A. J. M Carlin, Marion L. Clark (née Robertson), Matilda J. Clerk, W. P. Cockshott, N Conley, J. Cook, [4]W. F. Coulson, Isobel B. Craighead, W A. Cranston, Janet S. Darling, R. D. McC. Davie, A. R. Dawson, K. S Deas, Catriona M. Dempster, Pamela M Dodson, Alice B. Doherty (née Ritchie), Eleanor J. Durrand, Frances M. Falconer, Helen L. A. P. Fermie, Mary C. R. Fisher, H. M. Flett, Mary L. Fraser, J. A. G. Graham, P W. Grant, G. H. Hardie, E. R. Harris, Muriel G. Hartley, Susan E. Herdman, J. A. Hislop, Sheila S Hume, R. S. M. D. Inch, T. T. S Ingram, J. J. Ironside, Ailine M W. James, D. A. Johnson, I. M. Johnstone, L Kaufman, Margaret Kennedy, I. H. Kidd, [4]R. Kilpatrick, J. D E Knox, A Koch, J. A. Krawiecki, K. Krnjevitch, Janet M. Lamont, J. A H. Lee, Anne P. Lerpinière, Isabel J. Lim, J. A. Liver, M D W. Low, Elizabeth Y. McDonald, M. S. Macdonald, Beryl B. MacKenzie (née Grenfell), W. A. N Mackie, Sheila L. McKinlay, I. F. MacLaren, [3]Catherine M. U. Maclean, D. W. MacLean, Edith M McLean, J. D. F. McLean, K. F. M. MacLennan, T. J. McNair, D. M. MacPhee, D. M. McSwan, F. Malcolm, [3]Annie B Mann, Helen F. Martin (née Steele), G. H. Matheson, J. H. M. Miller, J. L. Miller, V. G. Milne, C. J. Morris-Mancor, Winifred A. Morton, Helen M. C. S. Mowat, Catherine R. Munnoch, J. H. Neill, J. E. Newsam, H. M. S. Noble, B Nolan, S. E. N.-A. Otoo, J. A. Owen, Rosemary E. T. Philp, Hilary R. Pullon, Helen M. Roberts (née Rebalska), A. D. Robertson, Elizabeth MacK Ross, Joan M. Russell, Helen H. Scott, H. G. Seed, R. L. Simpson, Krystyna M. Slawinska (née Andrzejowska), Lesley D Smith, J. S Stark, T. Stevens, Sheila M. Stewart, I. B. Sutherland, H B. Torrance, Dorothy I. Troup, Margaret A. Tubbs, G McD. A. Turner, W. B. Vallance, I R. Verner, Pearl A. Walker, Edith J. Warner, Phoebe M. White, J. McA. Williams, C W. M. Wilson, D. I. T. Wilson, Janet W. Worling, Mary E. S. Wylie, G. Young, [3]R. Yule.

B.Sc.—In the Department of Pure Science: [4,6]A. MacFarlane, M.B., Ch.B.

The following diplomas were awarded:

D.P.H.—R. S. F. Adam, E. Akwei, [4]K. H. Black, Jean A. Gemmell, D. W. Horn, [4]J. A. Leitch, J. P. Sexton, L. Sheldon, [4]J. L. Watson.

D.I.H.—W. Bolliger, [4]W. H. Graham, A. K. Niyogi.

D.T.M.&H.—Mary A. Ashton, M. Davey-Hayford, A. H. Dunnett, S. C. Ghosh, P. M. Kirkwood, S. A. Mannan, R. Park, J. M. U. Philip, S.-W. Wang.

DIPLOMA IN MEDICAL RADIODIAGNOSIS.—Agnes M. Macgregor, J. Mackenzie, C. D. Preston, D. F. Ross.

DIPLOMA IN MEDICAL RADIOTHERAPY.—J. D. Crowley, J. Milligan.

The following scholarships, bursaries, prizes, etc., were awarded in the Faculty of Medicine. *Cameron Prize in Practical Therapeutics,* D. Bovet (Rome). *Ettles Scholarship and Leslie Medal,* P. G. Aungle and R. Kilpatrick (equal). *Scottish Association for Medical Education of Women Prize, Buchanan Scholarship in Obstetrics and Gynaecology, Mouat Scholarship in the Practice of Physic, Dorothy Gilfillan Memorial Prize,* Catherine M. U. Maclean. *James Scott Scholarship in Obstetrics and Gynaecology,* Annie B. Mann. *Murchison Memorial Scholarship in Clinical Medicine,* C. W. M. Wilson. *Whaitt Research Scholarship,* W. Tomaszewski. *Gunning Victoria Jubilee Prize in Physiology,* I. F. Sommerville. *Gunning Victoria Jubilee Prize in Pathology,* G. M. Wilson. *Beaney Prize in Anatomy and Surgery,* R. Kilpatrick (*proxime accessit,* Margaret Kennedy). *Keith Memorial Prize in Systematic Surgery and Lawson Gifford Prize in Obstetrics and Gynaecology,* R. Kilpatrick. *Singapore Medal,* A. H. Banton. *Annandale Medal in Clinical Surgery,* Margaret Kennedy. *Murdoch Brown Medal in Clinical Medicine,* G. Young. *Ellis Prize in Physiology,* W. E. Balfour. *Wightman Prize in Clinical Medicine,* C. W. M. Wilson. *Pattison Prize in Clinical Surgery,* J. R. Brown. *Stirton Bursary,* D. N. S. Kerr. *Colonel Thomas Biggam Memorial Medal and Prize in Pathology,* B. C. Paton. *Lewis Cameron Undergraduate Prize in Bacteriology,* D. N. S. Kerr and D. McIntyre (equal). *Maclagan Prize in Forensic Medicine,* M. R. King. *Wellcome Medal and Prize in the History of Medicine,* S. Polsky. *Cunningham Memorial Medal and Prize in Anatomy,* W. D. Smith. *Senior John Aitken Carlyle Bursary in Anatomy and Physiology,* J. H. Tait. *Whiteside Bruce Bursary,* L. Gilbert. *Ian Oswald Prizes in Anatomy,* W. Harrison and J. K. Morrison. *Robert Wilson Memorial Prize in Chemistry and Vans Dunlop Prize in Physics and Chemistry,* P. H. Jaques. *Vans Dunlop Prize in Botany and Zoology,* W. C. Constable. *MacGillivray Prize in Zoology,* W. C. Constable (*proxime accessit,* Margaret C. Holderness).

[1]Awarded medal for thesis. [2]Highly commended for thesis. [3]Commended for thesis. [4]*In absentia.* [5]With honours. [6]With second-class honours in pathology.

UNIVERSITY OF DURHAM

Alfred Alexander Harper, M.D., has been appointed to the Chair of Physiology tenable at King's College, Newcastle-upon-Tyne.

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY.—A. I. Black, J. M. Burbury, D. McC. Gregg, S. J. Hinds, B. M. Jacobson, T. M. Prossor, R. Singh, Z. L. Szur.

M.S.—*Branch I (Surgery):* C. J. Longland, P. P. Rickham. *Branch IV (Otology, Rhinology, and Laryngology):* L. F. W. Salmon.

Claud Foster Barwell, M.B., B.Chir., has been appointed to the University Readership in Bacteriology tenable at the London Hospital Medical College, from October 1.

John Joseph Pritchard, B.M., B.Ch., has been appointed to the University Readership in Anatomy tenable at St. Mary's Hospital Medical School, from October 1.

Harold Charles Stewart, M.D., Ph.D., has been appointed to the University Readership in Pharmacology tenable at St. Mary's Hospital Medical School, from October 1.

UNIVERSITY OF MANCHESTER

Robert Francis Leslie Logan, M.D., M.R.C.P., C.P.H., has been appointed Part-time Lecturer in Occupational Health.

UNIVERSITY OF BIRMINGHAM

In Congregation on July 2 the honorary degree of D.Sc. was conferred on Sir Howard Florey, Ph.D., M.D., F.R.S., Professor of Pathology in the University of Oxford, and on Francis Peyton Rous, M.D., Pathologist, Rockefeller Institute for Medical Research, and a Foreign Corresponding Member of the British Medical Association.

The following medical degrees were conferred in Congregation on July 2:

M.D.—[1]J. J. Elkes, [1][3]Margaret D. Thompson, W. D. Carruthers.

Ch.M. *(ex officio).*—E. B. C. Hughes.

M.B., Ch.B.—[2]F. B. Buckley, [2]Sheila G. S. Burnie, [2]V. W. M. Drury, [2]Margaret T. England, [2]J. A. Ireland, [2]Lillian F. Jones, [2]Ann L. Reynolds, [2]Sylvia M. Saddington, June M. Astill, C. G. Berry, Jean E. Buller, B. W. M. Bushell, R. M. Butler, Winifred N. Chamberlin, E. W. Clarke, J. A. G. Clarke, R. F. Crampton, M. P. Creedy-Smith, J. R. Cross, D. H. Davies, W. R. Davies, R. F. Dingley, Margaret G. Douglas, F. J. Ensell, Thelma P. Higginson, P. D. Hooper, I. Hyde, Marjorie E. Johnston, J. E. Keen, Jean M. Kennedy, N. G. Kirby, Ruth L. Lawson, Bridie O. Lyons, D. F. J. Malins, M. R. Mellor, B. R. Middleton, Jill Prichards, I. Robinson, R. G. Robinson, D. S. Rowe, Brenda W. Stevens, P. J. Stevens, K. Wade, L. E. Wall, D. E. Wallis, I. M. Webster, Jean I. Whittle, V. Zuck, [3]B. B. Jakeman, [3]Elsie M. Wormington.

Dr. A. B. L. Beznak has been appointed Lecturer in Physiology and Dr. C. N. Iland Lecturer in Bacteriology, both from October 1. Dr. J. H. Hirshman resigned his appointment as Research Fellow in Social Medicine on June 30.

[1]With honours. [2]With second-class honours. [3]*In absentia.*

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At an ordinary quarterly comitia of the College held on July 28, with the President, Lord Moran, in the chair, the following Fellows were elected officers for the ensuing year: *Censors,* J. Crighton Bramwell, R. V. Christie, J. F. Smith, A. H. Douthwaite; *Treasurer,* W. G. Barnard; *Registrar,* H. E. A. Boldero; *Assistant Registrar,* W. D. W. Brooks.

Sir Leonard Parsons was appointed Harveian Orator and Dr. E. R. Cullinan Bradshaw Lecturer, both for 1950. The following Lecturers were also appointed: Lumleian (1950), Dr. B. T. Parsons-Smith; Goulstonian (1950), Dr. Howard Nicholson; FitzPatrick (1950), Dr. William Brockbank; Croonian (1951), Dr. T. F. Fox; Oliver-Sharpey (1950), Dr. E. E. Pochin; Lloyd Roberts (1950), Lady Violet Bonham Carter; Humphry Davy Rolleston (1950), Dr. J. H. Dible; Bertram Louis Abrahams (1950), Dr. E. C. Dodds. The Baly Medal was awarded to Sir Edward Mellanby, F.R.S., for his services to physiology and his work on nutrition, with particular reference to the accessory food factors.

Lord Moran was elected the College representative on the General Medical Council and on the Governing Body of the British Postgraduate Medical Federation. The reappointment of Dr. J. A. Nixon as representative on the Court of the University of Bristol was confirmed, as was the appointment of Sir Arthur MacNalty as representative on the Royal Medical Benevolent Fund. Dr. W. W. D. Thomson was appointed representative of the College at the centenary celebrations of the foundation of the University of Belfast, at Queen's College, Belfast.

The following having satisfied the Censors' Board were elected Members of the College: D. E. Aikenhead, M.D., C. D. Alergant, M.D., S. Balasingam, M.D., J. Baragan, M.B., E. M. M. Besterman, M.B., J. E. Blundell, M.B., R. E. Bowers, M.D., J. F. Britto, M.D., D. E. St. J. Burrowes, M.B., L. J. Bussell, D.M., J. A. Chamberlin, M.B., Patricia Chippindale, M.B., E. S. Clarke, M.D., H. R. Colquitt, M.B., Lorna Cooke, M.B., Christine E. Cooper, M.B., J. E. Cotes, B.M., C. J. Don, M.B., A. S. Douglas, M.B., C. E. P. Downes, L.R.C.P., J. R. Edge, M.D., R. H. Ellis, M.B., J. D. Everall, L.R.C.P., P. R Fleming, M.B., R. V. Gibson, M.B., J. E. MacA. Glancy, M.D., J. M. Gooch, M.B., D. A. Gordon, M.B., R. G. Gornall, M.D., R. F. Griffith-Evans, M.B., L. N. Grunbaum, M.B., S. Grzybowski, M.D., R. O. F. Hardwick, M.B., D. S. Harling, M.B., W. C. Harris, M.B., W. Hausmann, M.D., J. C. Hogarth, M.D., M. Horwitz, M.D., Betty E. Howarth, M.B., June L. Howqua, M.D., E. C. Hutchinson, M.B., M. A. Jackson, M.B., J. A. James, M.B., O. Janus, M.B., S. E. M. Jarvis, M.B., A. M. Joekes, B.M., E. R. Jones, M.B., A. J. Karlish, M.D., R. C. King, M.B., A. Knudson, M.B., J. B. Lyon, M.B., R. F. Mahler, M.B., R. H. Meara, M.B., K. B. M. O. Megat, L.M.S., Margaret Middleton, M.B., E. W. Nation, M.B., K. A. Newton, M.B., J. A. Nightingale, M.B., G. O'Gorman, L.R.C.P., C. V. Patel, M.B., H. K. Pawsey, M.B., A. V. Price, M.B., S. G. Rainsford, M.D., Surgeon Captain, R.N., J. T. Rendle-Short, M.B., R. F. Robertson, M.B., K. C. Robinson, M.B., R. Sahu, M.B., F. D. Schofield, M.B., A. B. Sclare, M.B., G. A. Scott, M.D., W. A. McD. Scott, M.B., Major, R.A.M.C., F. W. Smith, M.B., I. O. Stahle, M.D., A. G. Stephenson, M.B., H. C. Stewart, M.D., H. T. Swan, M.B., B. E. R. Symonds, M.B., Cecily M. Tinker, M.B., D. Tomlinson, M.B., D. A. H. Trythall, M.B., A. S. Turner, M.B., D. A. J. Tyrrell, M.B., N. R. Venkatswami, M.B., G. R. Venning, B.M., R. G. Vine, M.D., D. G. Vulliamy, M.B., M. H. West, M.D., D. Whitfield, M.B., D. H. M. Woollam, L.R.C.P., Esme M. Wren, M.B., E. A. Wright, M.B., R. J. Young, M.B., Flight Lieutenant, R.A.F.

Licences to practise were conferred upon 117 candidates (including 28 women) who have passed the final examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the necessary by-laws: C. A. McC. Aitken, G. W. Bainbridge, J. F. R. Ball, Q. A. Bari, Eleanor H. Barrington, A. T. Barwood, L. Bernstein, J. A. Blundell, I. I. Bornstein, Christine A. Bratt, J. E. Breese, Patricia L. Broadhead, D. E. Brown, H. J. Burns, R. A. Chesterfield, R. E. Citrine, E. G. Clarkson, K. R. J. Coates, B. Crawshaw, P. J. Crosland-Taylor, J. R. Cross, Patricia A. Crowther, Thelma W. Dafforn, Brenda L. D'Arcy, D. M. Davies, I. B. Davies, Lorna C. Davies, J. G. Elliott, G. Ellis, Valerie M. Ellis, K. A. Etherington, M. N. Fergusson, Barbara M. Fessey, O. O. F. Ffooks, G. Fleet, E. A. Foreman, W. G. C. Forrester, Yvette A. P. Franklin, R. Gathercole, Patricia M. Gilbert, H. S. Glatt, Helen Gordon, H. Gough-Thomas, S. S. Grové, A. O. Hagger, R. E. Hancock, Josephine Harper, W. H. Harper, P. H. R. Hawkes, K. M. Herd, Patricia Herdman, J. J. B. Hobbs, T. H. Hughes, Sheila M. H. Hugh-Musgrove, Margaret M. Ives, H. Jackson, C. H. James, W. B. Jennett, C. H. Jones, P. Kelly, I. Kent, D. S. Kerr, Ann Kiln, W. B. Knapman, N. B. Kreitman, K. Kuczynski, J. W. Latham, Mary I. Legg, J. C. Linn, H. K. N. Lister, Marcia McArthur, J. Mander, W. K. Marshall, Pamela G. L. W. Mason, S. N. Mathur, D. G. May, J. S. Mehta, Margaret L. Meikle, B. R. Middleton, J. B. Millard, D. D. Miller, K. E. Mortimer, G. M. Muller, Q. F. Neethling, N. H. Newman, R. L. Newman, G. J. Nicholas, D. H. Nixseaman, P. L. Norman, C. P. B. Parry, P. T. Perkins, C. D. Peters, S. T. H. H. Pilbeam, K. N. J. Pocock, C. O. M. Priday, Suzanne L. Quittner, Joselen Ransome, J. A. Rassell, Regina Reif, W. M. Savery, H. Schlossmann, P. B. Schofield, E. M. Sklar, June M. Smith, Susan Simpson, B. Singh, J. G. Sowerbutts, G. D. Stones, Medora Storkey, J. C. Sumption, F. Tavill, J. M. Thomas, P. W. Thompson, W. L. Timmins, I. M. Webster, Jean I. Whittle, W. B. M. Young.

Diplomas in Tropical Medicine and Hygiene, in Public Health, and in Physical Medicine were granted, jointly with the Royal College of Surgeons of England, to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—Y. G. Abdelal, J. P. Satterwhite, A. F. H. Stewart, S. W. W. Terry.

DIPLOMA IN PUBLIC HEALTH.—A. Bashir, B. A. Bhatti, Mary Brooks, T. H. Elias, J. E. Francis, Joan K. Griggs, W. E. Hadden, D. G. Levis, G. K. Lim, J. H. F. Norbury, Alexandrina M. M. Parker.

DIPLOMA IN PHYSICAL MEDICINE.—M. Fletcher.

Diplomas in Anaesthetics and in Medical Radiotherapy were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of June 25 (p. 1145).

Diplomas in Medical Radio-Diagnosis were granted, jointly with the Royal College of Surgeons of England, to D. Chisholm and J. J. Wallis and to the other successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of June 25 (p. 1145).

Diplomas in Laryngology and Otology and in Psychological Medicine were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of July 30 (p. 292).

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a meeting of the College held on July 19, with the President, Dr. W. D. D. Small, in the chair, the following were elected to the Fellowship: D. E. Sands, A. W. S. Thompson, C. F. J. Cropper.

Diplomas of Membership were conferred on the following: R. G. Lendrum, J. I. Lipschitz, R. W. D. Turner, R. M. M. Hunter, A. C. S. Iyer, A. P. Littlewood, W. Gordon, Muriel M. D'Souza, B. E. Cohen, J. H. Taylor, J. O. Craig, J. W. Farquhar, K. Rhaney, G. Mundel, D. Cappon, T. C. Noble, F. W. A. Turnbull, J. S. Calder, R. T. Ritchie, R. S. Walker, A. B. Sclare, J. D. Matthews.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a reception held on July 25 the Honorary Fellowship of the College was conferred on Mr. Victor Ewing Negus, M.S., F.R.C.S., President of the Fourth International Congress of Otolaryngology held in London last month, and, *in absentia*, on Dr. Chevalier Jackson, Professor of Bronchology in Temple University, Philadelphia, U.S.A. The first Honorary Fellowship in Dental Surgery of the College was conferred on Mr. William Guy, LL.D., F.R.C.S.Ed., H.D.D., former Principal of the Edinburgh Dental Hospital and School. Honorary Fellowships in Dental Surgery were also conferred on Professor Kent Thoma, Professor of Aural Surgery in Harvard University, and on Professor Robert Vivian Bradlaw, M.R.C.S., L.R.C.P., F.D.S., Dean of the Faculty of Dental Surgery, Royal College of Surgeons of England.

The Honorary Fellowship in Dental Surgery of the Royal College of Surgeons of England was also conferred on Mr. Guy. Professor Bradlaw, who presented it, said that it was fifty years ago that Mr. Guy had succeeded Bowman McLeod as Dean of the Edinburgh Dental Hospital and School, and to his endeavour might be ascribed the deservedly high reputation of that great school. To his vision they owed the Dentists Act of 1921, the charter of their profession: from his researches came advances in dental anaesthesia; and his skill and wide experience laid the foundations of their modern concept of maxillo-facial surgery. A fine scholar, a skilful surgeon, an outstanding teacher, and an able administrator, he brought distinction to the Roll of Fellows in Dental Surgery of the Royal College of Surgeons of England. If Carlyle was right when he said that statesmanship was to provide for posterity, William Guy was indeed a statesman.

At a meeting of the College held on July 27, with Mr. Frank E. Jardine, President, in the chair, the following candidates, having passed the requisite examinations, were admitted Fellows: C. E. L. Allen, F. Baar, A. J. Biesman-Simons, C. S. Campbell, B. C. Dastur, Patricia R. Davey, K. Drummond, J. M. E. Jewers, D. H. King, G. L. McEwan, I. W. MacPhee, J. J. MacPherson, R. M. Nadkarni, M. A. Radwan, T. K. Raju, T. J. Reid, M. H. Saadi, N. T. Sampanthan, H. Sayeed, R. N. Sinha, G. Smith, H. J. M. Stratton, P. A. Thorpe, H. S. Trafford, H. V. Wingfield.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College held in the College House on July 23, with the President, Sir William Gilliatt, in the chair, Professor Hilda Nora Lloyd was elected President and will assume office in October. Mr. John Eric Stacey and Dr. V. B. Green-Armytage were elected Vice-presidents.

The following officers were re-elected: *Honorary Treasurer*, Mr. Arthur A. Gemmell; *Honorary Secretary*, Mr. Humphrey G. E. Arthure; *Honorary Librarian*, Mr. Frederick W. Roques; *Honorary Curator of the Museum*, Mr. Aleck W. Bourne.

The following candidates were elected to the Membership of the College: A. B. Backus, Jessie E. C. Baird, T. E. C. Barns, A. Bhagat, D. H. Blakey, V. Y. Bockner, S. C. Bose, M. B. Bruce, R. C. Cummin, Mona M. Davin-Power, R. G. Denniss, H. Doberman, T. Dougray, L. W. D. Drabble, C. T. F. Ealand, G. K. Emsley, G. M. Evans, J. J. Foley, P. S. Gardner, G. W. Garland, H. K. B. Geiser, Elizabeth Gilbertson, Marie P. S. Grant, G. T. Hammond, J. C. Harvey, I. Henderson, J. A. Henderson, D. W. Hendry, R. W. Hutchinson, E. W. Ilangantileke, E. P. Jones, F. G. E. King, J. M. King, E. W. Kirk, Joan E. M. Lambert, D. Latto, J. G. Lawson, F. H. Leckie, E. M. Leyland, J. W. F. Lumsden, J. M. McCracken, I. MacGillivray, H. N. Mansfield, W. G. Millar, R. Moolan-Feroze, Ll. O. Morgan, M. R. Neely, F. C. R. Picton, J. G. Reynolds, N. A. Richards, S. Riterband, T. W. Roddie, J. H. Routledge, C. A. Samad, E. M. Sandler, Olive C. Sandys, J. W. F. Scrimgeour, S. Sen, J. C. Shelton, Norah P. Sherlock, A. Sinnatamby, J. A. McC. Smith, Doreen M. J. Stracey, A. B. Swarbreck, J. L. Taylor, S. D. Tewary, J. Watson, G. F. J. Williams.

The Services

Surgeon Rear-Admiral F. G. Hunt, C.B.E., R.N., has been appointed Honorary Physician to the King in succession to Surgeon Rear-Admiral J. A. Maxwell, C.V.O., C.B.E., K.H.S., R.N., who has been placed on the Retired List.

Surgeon Lieutenant-Commander J. A. Shepherd, R.N.V.R., has been awarded the R.N.V.R. Decoration.

Captain (now Major) R. M. Vanreenan, R.A.M.C., has been awarded the Efficiency Medal (Territorial).

The Efficiency Decoration has been conferred upon Majors H. Dickie, C. H. Johnson, and J. L. Warner, R.A.M.C., T.A.

DEATHS IN THE SERVICES

Colonel JOSEPH DALRYMPLE died on July 17 at the age of 80. He qualified at Edinburgh in 1899, having already served with the Bechuanaland Field Force in the Langeberg Rebellion in 1897. In 1900–1 he served in the South African War, gaining the Queen's Medal with five bars, and he served throughout the war of 1914–18, being mentioned three times in dispatches. He received the O.B.E. in 1918, and was made a C.M.G. the following year. He had published work on the restoration of the sick and wounded to the forward areas and on the treatment of malaria-infected troops.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ending July 16. [No. 28

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949 (a)	(b)	(c)	(d)	(e)	1948 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

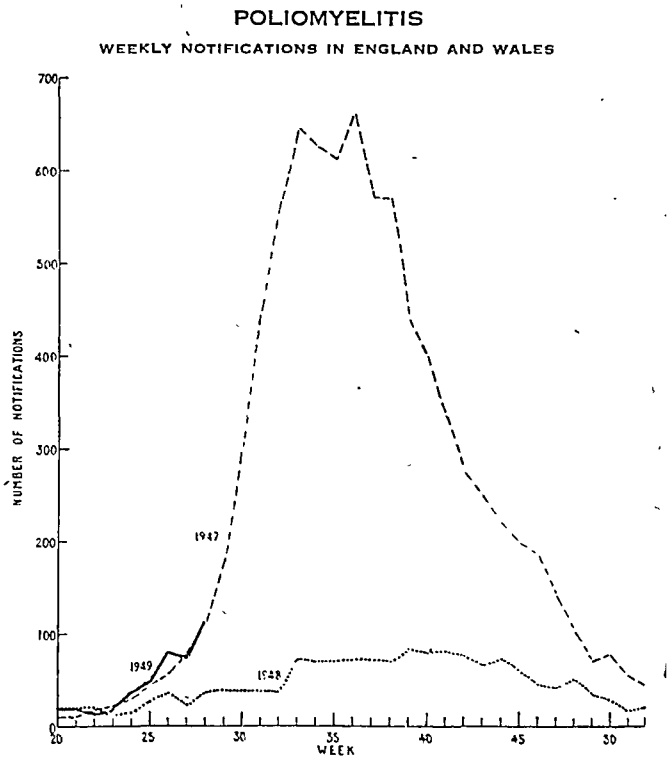
Rate per 1,000 total births (including stillborn)			21					31		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.



§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

The rise in the notifications of poliomyelitis (39) was due to increases in four counties; these counties accounted for 56 of the 112 cases. The largest returns during the week were Yorkshire West Riding 19 (Sheffield C.B. 4, Batley M.B. 4, Wortley R.D. 3); Southampton 14 (New Forest R.D. 12); London 12 (Camberwell 3, Lewisham 3); Middlesex 11 (Finchley M.B. 5, Hornsey M.B. 3); Devonshire 8 (Okehampton R.D. 4); Lancashire 6; Gloucestershire 5 (Bristol C.B. 4).

The number of notifications in the week ended July 23 was poliomyelitis 96 (112), polio-encephalitis 3 (5). (Figures for the previous week are shown in parentheses.) This is the second time since the seasonal rise definitely began in the week ended June 11 that the weekly notifications have been fewer than those of the previous week. In 1947 the rise was remarkably steady once it had set in, and the figure for the week ended July 19, corresponding to the present week, was 193. It is possible that this may portend a flattening of the curve of incidence.

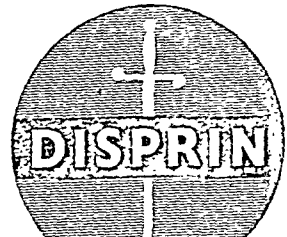
Multiple cases (poliomyelitis and polio-encephalitis together) were reported from the following counties: London 7 (13), Berkshire 3 (2), Cumberland 2 (2), Devon 7 (9), Essex 4 (3), Gloucester 2 (6), Lancashire 8 (7), Leicestershire 6 (2), Middlesex 11 (11), Northumberland 2 (0), Southampton 8 (14), Suffolk East 2 (0), Suffolk West 3 (1), Surrey 3 (4), Sussex East 2 (2), Yorks West Riding 17 (19).

Film for General Public

In addition to the film for doctors, "Polio: Diagnosis and Management," mentioned in this column last week, a short film for the general public entitled "Johnny Green in his Fighting Chance" has been made and will be shown in ordinary cinemas from Aug. 8. Copies will be available in the Central Film Library, Imperial Institute, South Kensington, from about Sept. 1.

Discussion of Table

In *England and Wales* decreases were reported in the number of notifications of measles 195 and cerebrospinal fever 22, while increases were recorded for scarlet fever 97, acute poliomyelitis 39, and paratyphoid fever 18. There were 278 fewer



DISPRIN

Stable tablets which dissolve in water to form a neutral solution of aspirin which is pleasant to take

EVEN IN SMALL DOSES ordinary aspirin, which is acid and almost insoluble, may act as an irritant to the gastric mucosa, producing inflammatory changes visible on gastroscopy. In large or prolonged doses it also tends to deplete the systemic alkali reserve.

Calcium aspirin has advantages over ordinary aspirin in these respects. But its presentation in the form of a tablet which, under ordinary conditions of storage, would remain stable and readily soluble, has hitherto met with difficulties. In Disprin tablets these difficulties have been overcome. Disprin tablets are stable, but they readily dissolve in water to form a substantially neutral, palatable solution.

Clinical trials, conducted in leading hospitals, have shown a remarkable freedom from gastric disturbance when Disprin is used.

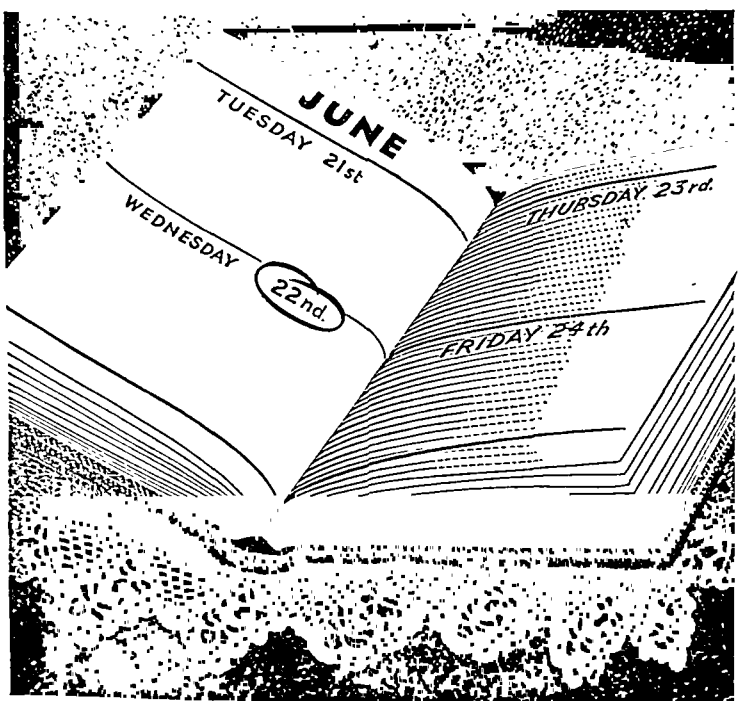
Bottle of 26 tablets, price 2/- including Purchase Tax.
On prescription Disprin is free of Purchase Tax.
Clinical sample and literature supplied on application.

STABLE, PALATABLE, NEUTRAL, SOLUBLE CALCIUM ASPIRIN

RECKITT AND COLMAN LTD., HULL AND LONDON. (PHARMACEUTICAL DEPT., HULL)

BRONCHIAL ASTHMA

NEODRENAL
BRAND
ISOPROPYL ADRENALINE



THE NEW 'ORAL' ADRENALINE

A potent bronchodilator: well tolerated: prompt in action: adrenaline injections unnecessary: superior to ephedrine. Issued in the form of tablets for sublingual use and a spray solution for oral inhalation.

Literature and samples on request

A Product of the "SAVORY & MOORE" *Group*

SAVORY & MOORE LTD.
WELBECK STREET, LONDON W.1
Telephone: WELbeck 5555 *Telegrams:* Instruments, Wesdo, London

Average dosage for dysmenorrhœa:

'Progynon' B Oleosum: Three injections of 10,000 i.b.u. during the first half of the intermenstruum.

'Oraluton' & 'Oraviron' Two to three tablets of 5mg. daily during the week preceding menstruation.

'Veramon': Four or five tablets daily during the painful period.

Full details of treatment will gladly be provided on request.

APPOINTMENT WITH FEAR

The Treatment of Painful Menstruation

PARENTERAL administration of 'Progynon' B Oleosum (œstradiol monobenzoate) probably provides the most effective fundamental method of treatment in the majority of cases of dysmenorrhœa of hormonal origin, the ætiology of which is not apparent. In such cases which, however, do not respond to this therapy, the oral administration of the progestogen 'Oraluton' (ethisterone) or the androgen 'Oraviron' (methyl testosterone) frequently proves effective and is worthy of trial.

Apart from hormonal therapy, immediate symptomatic relief can always be ensured in all types of dysmenorrhœa by the oral administration of tablets of 'Veramon' (barbitone-amidopyrine compound).

BS
BRITISH SCHERING LIMITED

167/169, GREAT PORTLAND STREET, LONDON, W.1.

351/H

notifications of food-poisoning than in the preceding week. A very small rise in the incidence of scarlet fever was recorded in every region of the country, but no change of any size occurred in the local trends. The largest decreases in the notifications of measles were Kent 170, Middlesex 46, Yorkshire West Riding 42, and the largest increases were Lancashire 37, Glamorganshire 31. The only variations of note in the local trends of diphtheria were a decrease of 5 notifications in London and an increase of 6 in Lancashire. The largest fluctuations in the returns of whooping-cough were a decrease of 38 in Essex and an increase of 31 in Lancashire.

The rise in paratyphoid fever occurred in Lancashire, where the chief centres of infection were Liverpool C.B. 29 and Crosby M.B. 6. Dysentery decreased throughout the country except in Warwickshire, where in Warwick R.D. the notifications rose from 2 to 34. The largest outbreaks of food-poisoning notified were the City of London 31 and Essex, Chingford M.B. 30.

In *Scotland* decreases were recorded in the number of notifications of scarlet fever 25, diphtheria 10, and a rise of 27 was reported for measles. The chief centres of dysentery were the cities of Glasgow 15 and Edinburgh 8. The decline in scarlet fever was confined to the western area, and a slight rise occurred in the south-eastern area.

In *Eire* a decrease occurred in the number of notifications of measles 24, while increases were recorded for whooping-cough 27, scarlet fever 21, and diarrhoea and enteritis 16. The experience of Dublin C.B. was mainly responsible for the rise in scarlet fever and diarrhoea and enteritis. The increase in whooping-cough was due to an outbreak at Dublin, Balrothery R.D., involving 30 persons.

In *Northern Ireland* decreases occurred in the number of notifications of measles 15 and whooping-cough 12, due mainly to the experience of Belfast C.B.

Week Ending July 23

The notifications of infectious diseases in England and Wales during the week included : scarlet fever 1,157, whooping-cough 2,004, diphtheria 76, measles 5,052, acute pneumonia 329, cerebrospinal fever 28, acute poliomyelitis 96, dysentery 90, paratyphoid fever 54, typhoid fever 8.

Medical News

Malta University Rector's Visit

Dr. J. A. Manché, Rector of the University of Malta, began a three-weeks visit to Britain under the auspices of the British Council on July 25. He is visiting laboratories, medical schools, and teaching hospitals to see teaching methods. Dr. Manché was appointed senior medical officer in the Malta Medical and Health Department in 1937. While holding this post he was appointed professor of physics in 1943, in which subject he has always been deeply interested. He became Rector of the University last year.

Gift for Nuffield Orthopaedic Centre

Lord Nuffield has given £50,000 to the Nuffield Orthopaedic Centre at Oxford. The centre offers special facilities and training for orthopaedic specialists from all over the world and students from the Commonwealth.

Great Ormond Street War Memorial

A bronze memorial tablet has been erected to the memory of members of the staff of the Hospital for Sick Children, Great Ormond Street, who gave their lives during two world wars. The memorial was unveiled on July 27 by Sir Lancelot Barrington-Ward, consulting surgeon to the hospital and former chairman of the medical committee. Sir Lancelot, who was invited to perform the ceremony by the chairman of the hospital, Mr. T. H. Bischoff, said that the tablet commemorated 16 men and women, all of whom were on active service in one or other of the wars. They had served the hospital in various capacities—as physicians, surgeons, nurses, electricians, and porters. All of them were members of its fellowship and all had rendered devoted service. The tablet was set by the main doorway of the hospital, where it would remind those passing through of the men and women who had made the great sacrifice for the nation and its children. After the unveiling, the simple ceremony was concluded by prayers of dedication and thanksgiving said by the hospital chaplain, the Rev. R. Mercer Wilson.

Ligue Européenne contre le Rhumatisme

At a general meeting of the Ligue held in Paris on May 14, with Professor M.-P. Weil in the chair, Dr. W. S. C. Copeman (Great Britain) was elected president for the next two years. The next congress will be held in Barcelona in 1951.

Directory of Collections of Micro-organisms

One of the recommendations of the British Commonwealth Scientific Official Conference, 1946, was that a directory of the important culture collections of the Commonwealth should be prepared. Duplicated copies of the "Directory of Collections of Micro-organisms maintained in the United Kingdom and Crown Colonies" and of the "Catalogues of Arthropods, Helminths, Molluscs, and Protozoa of Interest to Medical and Veterinary Workers" are now available free on request, the former from the Secretary, United Kingdom National Committee of the British Commonwealth Collections of Micro-organisms, 38, Old Queen Street, Westminster, London, S.W.1, and the latter from the Director, Laboratory Animals Bureau, Royal Veterinary College, Royal College Street, London, N.W.1.

Lord Webb-Johnson Lecture

The Council of the Royal College of Surgeons decided at a meeting on July 28, on the recommendation of the Faculty of Dental Surgery, to institute an annual dental lecture entitled the Lord Webb-Johnson Lecture. It will be a College lecture, and will be given on invitation from the College. It commemorates the indebtedness of the dental profession to Lord Webb-Johnson, who was instrumental in founding the Faculty of Dental Surgery.

Freedom of City

The freedom of the city of Verona has been conferred on Sir Alexander Fleming.

Dean Resigns

Professor J. M. Mackintosh has resigned from the position of Dean of the London School of Hygiene and Tropical Medicine, but will continue to teach in the school as Professor of Public Health. We understand that the school has decided to appoint a whole-time Dean.

COMING EVENTS

General Meeting of Psychiatrists

A meeting, open to all psychiatrists practising within the South-West Metropolitan Region, will be held at B.M.A. House, Tavistock Square, London, W.C., on Thursday, Aug. 11, at 2.30 p.m.

Veterinary Congress

The National Veterinary Medical Association will hold its annual congress in London on Aug. 12–15 in conjunction with the International Veterinary Congress being held on Aug. 8–13. Dr. J. Peters, of Rotterdam, and Dr. J. Winsser, of Leiden, will present a paper on "Diseases of Household Animals Communicable to Man." Members of the B.M.A. will be welcome at this discussion, which is to be held at the Central Hall, Westminster, at 2.15 p.m., on Saturday, Aug. 13. Tickets of admission may be obtained from the General Secretary of the N.V.M.A., 36, Gordon Square, London, W.C.1.

First-aid and Nursing Courses

A course of first aid and nursing will be started under the direction of the St. John Association on Sept. 3 at the new Brigade Training Centre, St. John House, 15 and 16, Collingham Gardens, London, S.W.5. All are eligible without obligation to join the Brigade. First aid will be dealt with in one week, home nursing in the following week, with an examination at the end of each week. Successful candidates will receive a

St. John Association certificate in either or both subjects according to the set of lectures followed. The training centre is also a social club and provides meals and accommodation for all taking part in the course.

Congress of Haematology

The Société Européenne Internationale d'Hématologie is holding a meeting in Montreux, Switzerland, on Sept. 15–17. The official languages of the congress are English, French, German, and Italian. Two subjects have been proposed for the main discussions: (1) haemolytic anaemias; (2) changes in blood proteins in blood dyscrasias. British haematologists may obtain particulars from Dr. A. Piney, 152, Harley Street, London, W.1.

SOCIETIES AND LECTURES

Friday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, Aug. 12, 12.30 p.m., "*Frontal Lobe and the Integration of Thinking*," by Professor G. Jefferson, F.R.S.

APPOINTMENTS

ASHCROFT, A. T., M.B., Ch.B., Regional Medical Officer, Ministry of Health.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—The following appointments are announced: *Consultant Physician in Ipswich Area*, J. W. Paulley, M.D., M.R.C.P. *Consultant Paediatrician in Ipswich Area*, R. M. Mayon-White, M.D., M.R.C.P., D.C.H. *Physician Superintendent at Ipswich Sanatorium*, G. R. McNab, M.D., F.R.C.P.

FERREIRA, H. P., M.B., B.S., Assistant Pathologist to Queen Charlotte's and Chelsea Hospitals at Chelsea Hospital for Women.

GREGORY, T. S. S., M.B., F.R.C.S (Ophth.), D.O.M.S., Ophthalmic Surgeon to Aylesbury and District Group of Hospitals, Oxford Regional Hospital Board.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—The following appointments are announced: *House-physicians*, J. C. Macaulay, M.B., B.S., M.R.C.P., D. McR. Hanna, M.D., M.R.C.P., M.R.A.C.P.; *House-surgeons*, L. H. Pimm, M.B., B.S., R. M. T. Walker-Brash, B.M., B.Ch.; *Part-time Surgical Registrar*, D. J. Waterston, M.B., F.R.C.S.

SOUTH-WESTERN REGIONAL HOSPITAL BOARD.—The following appointments at the hospitals indicated in parentheses are announced: *Pathologist*, G. Stewart Smith, M.D. (Royal Devon and Exeter Hospital, Exeter); *Assistant Orthopaedic Surgeon*, M. H. Salz, F.R.C.S. (Mount Gold Hospital, Plymouth, with clinical duties in other hospitals in area, as required); *Assistant Radiologists*, G. R. Airth, M.B., B.S., D.M.R. (Southmead Hospital, Bristol), and C. W. B. Woodham, M.R.C.S., L.R.C.P., D.M.R.E. (Royal Devon and Exeter Hospital, Exeter); *Assistant Clinical Pathologist*, C. H. Jellard, B.M., B.Ch. (Gloucestershire Royal Hospital); *Plastic Surgeon*, G. M. Fitzgibbon, M.D., F.R.C.S. (Frenchay Hospital, Bristol).

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bartolo.—On July 21, 1949, at Blue Sisters Hospital, Malta, to Jean (née Callie), wife of Dr. A. E. Bartolo, a son—David.

Benians.—On July 15, 1949, at North Middlesex County Hospital, London, N., to Edith (née Aiken), S.R.N., wife of Richard Benians, M.B., M.R.C.P., a daughter.

Beynon.—On July 27, 1949, in London, to Nora, wife of Dr. Arthur E. Beynon, a son.

Elphick.—On July 14, 1949, at Lagos, Nigeria, to Hilary Jean Elphick (née Haden), M.B., B.S., and Richard Michael Elphick, of King's College, Lagos, a daughter.

Freeman.—On July 23, 1949, at British Military Hospital, Vienna, to Frida (née Allibone), wife of Captain Roger Freeman, R.A.M.C., a daughter.

Gilmour.—On July 24, 1949, at Hayes, Middlesex, to Jean (née Macleod), wife of Dr. S. J. G. Gilmour, a son.

Goulden.—On June 19, 1949, at 94th British Military Hospital, Hamburg, to Margaret Fionnula (née Macrae), wife of Captain Richard Patrick Goulden, R.A.M.C., a daughter—Margaret Sheonagh.

Hirsch.—On July 22, 1949, at Leicester General Hospital, to Edna (née Sayer), S.R.N., S.C.M., wife of W. P. Hirsch, F.R.C.S.Ed., M.R.C.O.G., a son.

MacAuliffe.—On July 15, 1949, at Swindon, to Judy (née Baldry), wife of Richard MacAuliffe, M.D., a daughter.

Wharton.—On July 10, 1949, at 277, Stroud Road, Gloucester, to Jenny (née Morgan), wife of Dr. G. C. C. Wharton, a son.

MARRIAGE

Thomson—Milne.—On July 23, 1949, at Perth, Thomas Nairn Thomson to Nancy S. M. Milne, M.B., Ch.B., late of Wisbech.

DEATHS

Ackland.—On July 26, 1949, William Robert Ackland, M.D.S., M.R.C.S., of 5, Rodney Place, Clifton, Bristol, aged 85.

Anderson.—On July 25, 1949, at Craigbittern, Colvend, Dalbeattie, Kirkcudbrightshire, Alford William Anderson, T.D., M.D., J.P., aged 81.

Barr.—On July 22, 1949, at The Cairn, Oxlea Road, Torquay, James Barr, M.B., C.M., D.P.H., aged 81.

Brew.—On July 23, 1949, Richard William Brew, M.B., B.Ch., of 8, Herbert Terrace, Penarth, aged 78.

Cairns.—On July 24, 1949, at Edinburgh, Agnes Josephine Cairns (née Gardner), M.B., Ch.B., D.P.H.

Elwell-Johnston.—On July 26, 1949, at University College Hospital, London, Loiza Elwell-Johnston (née Elwell), M.R.C.S., L.R.C.P., aged 77.

Fegan.—On July 26, 1949, at Leverstock Green, Herts, John Herbert Crangle Fegan, M.R.C.S., L.R.C.P., aged 77.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Bedsores

Q.—*A woman of 40, bedridden for some years with disseminated sclerosis, has some very bad bedsores. For several months she has had almost constant urinary incontinence, which makes treatment of the sores impossible. Is there any reason why a catheter cannot be inserted and left in, and can you suggest any palliative treatment?*

A.—Urinary incontinence should not prevent adequate treatment of bedsores; indeed, with good nursing care the sores can usually be healed in such a case. If the deformities referred to consist of severe flexion and adduction contractures of the lower limbs the task will be more difficult. An indwelling catheter may be tried for a few days, but is not always satisfactory. A rubber bed-pan, which the patient can lie on all day, like a rubber ring, is of very great help. The free use of diapers which have been sprinkled with boric acid solution and allowed to dry prevents much discomfort and also the ammoniacal odour.

Bedsores develop in such a case because the patient is left in one position for more than four hours at a time. The common propped-up position of the chronic invalid in bed throws nearly all weight on the sacrum. The patient should never be left like this for long; every four hours the position should be changed, but this involves removing all but one pillow and turning the patient fully on the side or face, if contractures allow. It is also worth noting that removal of all pillows in itself transfers much of the weight from the sacrum to the shoulders; while raising the foot of the bed with the patient lying flat is even better, and in difficult cases should be used for one period every day. Deep bedsores should seldom be packed, and then only very lightly, as the patient's weight on the dressing makes the bedsore deeper. An empty space stimulates free growth of granulation tissue. If flexion contractures have not yet developed, a daily period of lying prone on the face is specially valuable for all bedridden patients. This relieves sacral pressure, counters flexor spasms, and prevents the otherwise inevitable flexion deformities of hip, spine, and neck. The last point is not applicable to this particular question, but its importance demands emphasis. After a long illness a properly treated patient should be able to walk as erect as a guardsman; the curled-up victims whom one sees coming out on fine days exemplify how sadly our profession fails to counter the vicious flexion deformities of the infirm.

Oedema of the Newborn

Q.—*What are the modern views on the causation of spontaneous oedema of the newborn? Is vitamin E of any value in treatment?*

A.—Oedema of the newborn, apart from the hydrops of haemolytic disease, occurs principally in association with two conditions—sepsis and prematurity—but in neither is the causation at all clear. Certainly infants with severe infection develop oedema, first of the legs and later of other parts of the body, and it is usually, but not always, an ominous sign. It is often accompanied by anaemia, and is possibly associated in severe cases with heart failure. Treatment in such cases is of course directed at the infection. In premature and weakly infants who are not thriving oedema is also often found, sometimes indicated by an upward jump in the weight curve even before oedema becomes obvious. In this connexion it should be remembered that the infantile kidney, as McCance has shown, is poor at concentrating the urine, and if chlorides are being given, as in normal saline or even in milk, retention may occur and may explain the oedema in some instances. The serum protein level may be low in either of these conditions, but, as with hunger

oedema, there is not an absolute correlation. Oedema may occur with normal protein figures and not occur with low levels. In premature infants with a subnormal temperature the condition may be treated by the administration of thyroid as suggested by the late Eric Pritchard. He recommended *1/10 gr. (6.5 mg.)* for every 1 lb. (453 g.) of body weight daily for a few days. Congenital syphilis affecting the kidneys is a theoretical cause of oedema of the newborn, but ought never to be seen if routine antenatal investigation of all expectant mothers is carried out. Also theoretically, Milroy's hereditary oedema might begin to show in the newborn period. It is difficult to see what part vitamin E could possibly play in treatment of oedema of the newborn. Most mild examples clear up spontaneously, and any preparation or treatment used can thereby secure a spurious reputation.

Resuscitating Apparatus

Q.—*What are the latest views on the use of a resuscitating apparatus supplying oxygen with a fixed proportion of carbon dioxide in cases of drowning, carbon-monoxide poisoning, or electric shock? Is there much value in giving oxygen alone in any of these cases? Is carbon dioxide of value, and, if so, in what proportion?*

A.—Carbon dioxide is a stimulant to the respiratory and vasomotor centres. It is therefore logical to administer carbon dioxide along with oxygen in cases where the patient is suffering from anoxia and impaired respiratory function. The proportion usually recommended is 5 to 7% of carbon dioxide; appreciably higher concentrations may be deleterious. An appropriate oxygen–carbon-dioxide mixture is considered specially suitable in the treatment of severe carbon-monoxide poisoning, because the increased carbon dioxide not only stimulates the respiratory centre but also favours a more rapid dissociation of the carboxyhaemoglobin. Moreover, there may be an added value in that the hyperventilation occurring in the earlier stages of carbon-monoxide asphyxia causes a deficiency of carbon dioxide in the body. This latter argument does not apply in cases of drowning and electric shock, and the desirability of the addition of carbon dioxide to the inhalation mixture is probably not so great in these conditions. Nevertheless, it would seem reasonable to try the effect of a similar mixture where the respiratory movements are feeble and there is an obvious need for increased pulmonary ventilation. The beneficial effect of the carbon dioxide on the circulation should also be borne in mind. The administration can be combined with artificial respiration, and in most cases need not be unduly prolonged. If no oxygen–carbon-dioxide mixture is available, oxygen by itself should certainly be used.

Supplementary Vitamins

Q.—*Is there any justification for advising the routine administration of vitamins A and D to, say, a police force to increase vitality and resistance to infection?*

A.—There is not the slightest justification for advising this practice.

Anterior Pituitary Growth Hormone

Q.—*Will you please let me know if the isolated growth-promoting hormone of the anterior pituitary is obtainable; also the indications for use and recommended dosage.*

A.—No preparation of the isolated growth hormone is available, but there is on the market an extract of the anterior pituitary, standardized for the growth hormone (100 units per ml.) and also containing adrenotropic hormone. The dose recommended is 1 ml. daily intramuscularly. In the writer's experience this dosage is useless, and he has obtained results only with 5 ml. twice daily, which is both painful and expensive. The pure hormone has been isolated by Li, of California (*J. biol. Chem.*, 1945, **159**, 353), and in some unpublished experiments on dwarfs this failed to stimulate growth and even failed to produce nitrogen retention; both these effects, however, were obtainable in animals. The position as regards growth hormone is therefore unsatisfactory, even to the point of causing scepticism about the existence of a pure growth hormone. Thyroid and testosterone stimulate growth in suitable cases.

Fox-Fordyce Disease

Q.—*A female aged 20 has been suffering from Fox–Fordyce disease for the last two years, and in spite of expert treatment the condition seems to be at a standstill—in fact, it is becoming more painful in both axillae. Is the aetiology known, and is there any effective treatment?*

A.—Fox–Fordyce disease is an irritable papular eruption of axillae, pubes, and breasts related to apocrine-gland function. It depends on disturbances of endocrine function and is usually relieved by the administration of oestrogens. Local applications, including *x*-ray therapy, as employed in other types of prurigo are of little value in this affection.

Glutamic Acid for Mental Retardation

Q.—*Is glutamic acid likely to improve the intellectual performance of a boy of 8 who is not mentally defective but only somewhat retarded? The father rejects the boy because of his slowness, and any improvement would probably make a difference to this attitude. Please state the dosage and the method of administration. How long ought treatment to be continued, and are there any contraindications?*

A.—The evidence that administration of glutamic acid makes a real difference to retarded and defective children is not convincing. According to published reports, response varies greatly from individual to individual, so that while one child makes a striking advance others are unaffected or even drop points on intelligence testing. There is no indication that results differ with different types of defective. The numbers of patients so treated have not been large. L-Glutamic acid is given by mouth in doses which are to a considerable extent independent of age and determined by the response obtained, but beginning, say, with 2 g. thrice daily and increasing even up to 48 g. daily. It can be given as tablets, powder, or in capsule. Unpleasant effects may be indicated by gastro-intestinal upset. The patient described might perhaps benefit from this treatment, and ill effects need not be feared. It might in any case be good for the father's attitude—which may itself be partly the cause of the son's slowness—to try something in the way of treatment, and lead him to regard the boy more sympathetically. The inquirer is referred to the following articles: *Arch. Neurol. Psychiat., Chicago*, 1944, **51**, 446; 1946, **56**, 489; 1949, **61**, 275; *Psychosom. Med.*, 1947, **9**, 175; *Amer. J. Psychiat.*, 1948, **104**, 593; *J. nerv. ment. Dis.*, 1946, **104**, 263.

Menstrual Tension State

Q.—*Since her first pregnancy five years ago a woman of 29 has headache, irritability, depression, aching in the gums, and right low-abdominal pain starting a few days before and continuing till a few days after each menstrual period. The lochia were blood-stained for several weeks after the birth of the baby, and during lactation the mother often had night sweats. Tuberculosis was excluded. In 1947 the uterus was found to be pulled over to the right, but was normal in size and anteverted; the right ovary was tender on pressure, and at laparotomy was seen to be covered by a thick white capsule and contained a few small follicular cysts. It was removed, but histological examination failed to reveal any abnormality. After a few months the symptoms returned, with pain in the left side. The patient became pregnant again. After her confinement night sweating recurred, and for six weeks the lochia contained blood. On examination a well-anteverted but subinvoluted uterus was found. When her periods started again there was a return of the symptoms with in addition small papules on the body and face. A papular rash also developed on the baby, accompanied by colic and green stools. Can the mother's symptoms, including the ovarian tenderness, be due to an endocrine disturbance, affecting the baby by excretion of hormones in the milk? If so, can any treatment on an endocrine basis be suggested?*

A.—It is difficult to comment adequately on a complicated case history of this kind, and personal knowledge of the patient and her environment would seem to be important before coming to any final conclusions. There is nothing in the account to indicate an endocrine disturbance, nor is it likely that the upsets

in the baby were related to a noxious agent in the milk. Indeed, the whole picture suggests that the basis is one of over-anxiety. Colonic spasm is likely to be the cause of the left-sided pain and to give rise to occasional right-sided pain from the caecum. The abdominal discomfort has probably always been of bowel origin, and the ovary which was removed was blameless. The general disturbance associated with menstruation represents exaggerated molimina, amounting to what is sometimes called a "menstrual tension state," which again often has a psychological underlay. Night sweats, sometimes most profuse and disturbing, are common enough during the puerperium and early weeks of lactation, and in the absence of pyrexia they are not of any real significance. Persistence of red lochial discharge for six weeks after delivery is also not necessarily pathological. Cyclical ulceration of the mouth associated with menstruation and perhaps causing discomfort in the gums is a condition the cause of which is unknown. It may be an allergic manifestation, and is dealt with at some length in replies to questions in the *Journal* (Aug. 21, 1948, p. 408; March 15, 1947, p. 365; and June 15, 1946, p. 940).

Paroxysmal Tachycardia

Q.—*A male aged 73 has suffered from paroxysmal tachycardia for nearly 20 years, and the attacks seem to be increasing in frequency—though not in intensity. Treatment with quinidine appears to have little effect. Is there any other treatment that would decrease the number of paroxysms or abort or shorten the attacks?*

A.—If quinidine in doses of 5 gr. (0.32 g.) thrice daily has failed to influence the frequency or duration of the attacks, mepacrine 0.1 g. daily may be tried when attacks are particularly frequent. Although digitalis is usually contraindicated, it is helpful occasionally, and is always worth trying when other methods fail.

NOTES AND COMMENTS

Anaesthetics for Domiciliary Midwifery.—Dr. J. E. M. BARNES (Eye, Suffolk) writes: I was interested in the answer to the question about anaesthetics in domiciliary midwifery ("Any Questions?" July 9, p. 112). It was stated that the Cyprane inhaler could be adjusted to produce a concentration of "trilene" sufficient for general anaesthesia. I would like to know whether this was a theoretical assumption or based on practical experience. I have used one of these inhalers with complete satisfaction in purely domiciliary surroundings—but only in so far as analgesia is concerned. On occasion I have tried to induce anaesthesia, but not successfully. In one particular case forceps blades were positioned on the foetal head without untoward reaction, but as soon as traction occurred the patient resisted the manœuvre. It was a low-forceps delivery, and was terminated rapidly and smoothly, with no difficulty, after anaesthetizing with straight chloroform. I would be interested to know from others their experiences in this particular direction, because I am loath to follow trilene with chloroform as a routine, having, since the case quoted, run up against an alarming instance of cardiac arrest due presumably to vagal inhibition, which entailed resuscitation of mother, infant (white asphyxia), and, almost, the single-handed G.P.

Weight in Pregnancy.—Dr. F. R. KINKEAD ALLEN (Belfast) writes: Gain in weight during normal pregnancy ("Any Questions?" May 7, p. 831) is subject to rather wide variation. In the United States of America this gain appears to be more than in the British Isles. According to McIlroy and Rodway (*J. Obstet. Gynaec. Brit. Emp.*, 1937, **44**, 221), in a thousand cases the average total gain among primiparae was 11 lb. 3 oz. (5 kg.) and for multiparae it was 11 lb. 7 oz. (5.2 kg.), and they noticed that the older patients gained less in weight than the younger ones. According to Chesley (*Amer. J. Obstet. Gynec.*, 1944, **48**, 565) the average gain in weight may be generally ranked as 24 lb. (10.8 kg.); two-thirds of the normal women in his series gained between 18 and 35 lb. (8.1 and 15.7 kg.), but one-sixth gained more than 35 lb. (15.7 kg.). The total increase in any one case, however, is to some extent dependent on the woman's initial bulk, and Stander and Pastore (*Amer. J. Obstet. Gynec.*, 1940, **39**, 928) suggest that it should not exceed 25% of the pre-pregnancy weight. There are, however, many exceptions even to this, and gain does not take place regularly throughout pregnancy. In the first three months there is often little gain, and even a loss may be recorded, especially where a woman suffers from vomiting or anorexia. In the last two or three weeks there may also be a tendency to lose or to cease to gain weight. McIlroy and Rodway claim to have prevented the onset of toxaemia in patients showing excessive gain in a week by regulating diet and by increasing walking exercise. Emblin (*British Medical Journal*, 1949, **1**, 260) considers that the weekly gain during pregnancy should not exceed 8 oz. (0.22 kg.).

Bacteriology of the Throat.—Dr. W. B. ORME (Hove, Sussex) writes: One of the queries in "Any Questions?" (July 2, p. 39) was, "What is the normal bacteriology of the throat?" In answering, your specialist replied giving non-haemolytic streptococci of the *viridans* and *salivarius* types, Gram-negative diplococci of the *catarrhalis* group, slender Gram-negative bacilli of the *Haemophilus influenzae* family, and Gram-positive diphtheroids. Further on in his reply he refers to organisms which are recognized as pathogens, including *Staphylococcus aureus*, haemolytic streptococci, pneumococci, meningococci, and occasionally diphtheria bacilli. Not in the whole reply does he once mention the well-known Friedländer's bacillus, also known as *Bacterium mucosum-capsulatum* and other names; micro-organisms of this group are not infrequently associated with various respiratory infections in man, though in many cases these are considered as being simple secondary invaders. Yet they are commonly present in the nasopharynx of patients suffering from chronic sinusitis, and in some cases they are definitely pathogenic, accounting for 1% of all pneumonias—such cases have an exceptionally high case-fatality rate. Again, Friedländer's bacillus is one of the most difficult organisms to deal with, as it appears to be resistant to all modern bacteriostatic drugs. I am therefore surprised at its omission from your reply.

Ergotamine and Pregnancy.—Dr. K. D. SALZMANN (Reading) writes: Your answer to the query on ergotamine and pregnancy ("Any Questions?" July 2, p. 40) states that, "unless the patient's previous history suggests a special susceptibility to abortion or premature labour, ergotamine is unlikely to have any significant effect on the uterus, and its continued administration is therefore not contraindicated." A few years ago a consultant recommended to one of my colleagues a simple method of inducing labour. He advised giving one ergometrine hydrochloride tablet every morning until labour ensued. My colleague, at his next antenatal clinic, found three of his patients were about a fortnight postmature and unfortunately decided to try the ergometrine method of induction. It worked. All three mothers went into labour within three days. All three had spontaneous labours, and all three gave birth to macerated foetuses, although at the last antenatal examination the infants were alive. In addition to the above experience I recall a patient of mine who had reached term and developed a migrainous headache. I gave her a tablet of ergotamine tartrate. She started in labour, had violent pains, and gave birth—spontaneously—to a stillborn infant. In view of the experiences of my colleague and myself I think one should say that it is unwise to give ergotamine to a primigravida in the early months of pregnancy (before it is known whether she has any tendency to miscarriages) and rarely or never should it be given when the uterus is no longer inert—at term or during the last few weeks preceding maturity. There is one exception to the above rule. If the foetus *in utero* is dead, one might utilize the daily tablet of ergometrine or ergotamine as a means of inducing labour—particularly if massive oestrogen therapy has failed. I have known this done successfully on several occasions.

Corrections

Dr. E. K. PRITCHARD (Southwark) writes: It is not clear in the report of my remarks at the Commonwealth and Empire Tuberculosis Conference (July 16, p. 152) that domiciliary collapse therapy was first organized on a large scale in May, 1946, by Dr. C. H. C. Toussaint and myself in our respective Boroughs of Bermondsey and Southwark. Dr. Toussaint subsequently organized a similar scheme in the Borough of Willesden. The necessity for this form of treatment was the natural corollary of the success of the mass *x*-ray survey of cases with minor respiratory symptoms started in similar collaboration between Dr. Toussaint and myself in 1942. This survey brings to light a large number of early cases in urgent need of treatment.

The Hunterian Lecture by Dr. W. S. C. Copeman, published in the *Journal* of July 23 (p. 191), was incorrectly described as the Hunterian Oration.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY AUGUST 6 1949

THE SECRETARY REPORTS

N.H.S. SUPERANNUATION

The Minister of Health has laid before Parliament regulations amending the National Health Service Superannuation Scheme. Regulations on this subject are among the few which the Minister is not empowered to make under the N.H.S. Act without an affirmative resolution by both the Commons and the Lords. The amending regulations, which have now been approved by both Houses, are technical in character, and for the most part serve to tidy up points of difficulty and to bring the scheme into line with developments in other superannuation schemes in the past year. They include a provision designed to encourage pensioners to continue in employment for up to a further five years, by enabling them to increase the pension which they will ultimately get as a *quid pro quo* for the loss of pension while they continue to be employed in the service.

But the most important provision from the profession's point of view is the extension to consultants and specialists in contract with regional and teaching hospital boards of the option, previously limited to general practitioners on executive council lists, to remain outside the Government superannuation scheme and to receive from the Ministry an amount equivalent to the employer's contribution (8% of the net remuneration) towards the payment of insurance policy premiums. Full details of the conditions under which the option may be exercised have yet to be published. But on the general practitioner analogy it is reasonable to expect that consultants who have already made provision for retirement by endowment or deferred annuity policies will be able to opt out on satisfying the following requirements:

(i) The policies must not mature at an earlier age than 60; where a policy would under its original terms have matured before age 60, it may be recognized if its terms are modified so that it matures at or after age 60.

(ii) The premiums (or total premiums) must not be less than £150 per annum; alternatively, if the total annual premiums on existing policies are less than £150 per annum but not less than £50 per annum, these policies may be recognized on condition that the practitioner takes out forthwith a further policy which will bring the total premiums to at least £150 per annum on policies satisfying the conditions above.

(iii) The policies must not be assigned to any other person, or surrendered before maturity.

(iv) Payment by the Ministry of an amount equal to 8% of the practitioner's remuneration will continue only so long as the premiums on the policies continue to be payable.

(v) The policies must be produced for inspection on a request made to the practitioner by the Minister or by an employing authority on his behalf. Alternatively, a statement from the assurance company as to the nature of the policies may be submitted.

(vi) Premium receipts must be submitted to the Minister or to the employing authority for examination within one month after the date on which each payment of premium falls due.

These are the conditions which will obtain if the Ministry follows the precedents adopted in the case of general practitioners. The Ministry will shortly issue full details in a special leaflet which consultants and specialists will be able to obtain from regional hospital boards and teaching hospital boards of governors.

So complicated is the structure of this vast superannuation scheme that as soon as one anomaly is dealt with another appears. For example, the Medical Women's Federation has recently brought to light the fact that the scheme discriminates unfairly between married women who are employed in the health service and married women who are not so employed. In the latter case, the woman makes no contribution to the N.H.S. superannuation scheme, but qualifies for a widow's pension on her husband's death. In the former case the woman contributes to the scheme as a member of the Service, but loses the widow's pension on becoming entitled to a pension in her own right. In brief, a widow's pension which would otherwise be payable is not payable if the wife is herself receiving a pension under the regulations. This point is at present under discussion with the Ministry.

The Public Health Service

The dispute with the Associations of Local Authorities is now over. The Associations, following a meeting on July 26, agreed to participate in the Whitley machinery provided that its constitution provides that the decisions of the committee dealing with the remuneration and terms and conditions of service of public health officers are final, without need for confirmation by the functional council. It will be recalled that the Whitley proposals for the medical profession provided for a functional council and three main subcommittees, one dealing with consultants, one with general practitioners, and one with public health officers. The effect of the proviso of the Associations of Local Authorities is to ensure that these three subcommittees reach their conclusions without their being subject to the approval of the functional council as a whole. Similarly, no doubt, the remuneration of general practitioners will be determined by its subcommittee without the approval of a functional council which would include not only representatives of the Ministry but representatives of regional hospital boards and local authorities; and, of course, the same would apply to the subcommittee dealing with the terms and conditions of service and remuneration of consultants. The condition seems reasonable, and although it will have to be considered by the Ministry it need not be the cause of any prolongation of the dispute.

The Scottish representatives at the meeting on July 26 were not authorized to commit their association, but they are recommending it to participate. In the meantime, the ban on Scottish advertisements as well as those coming from local authorities in England and Wales will be lifted, although, of course, the final decision of the Scottish Association will be awaited with interest.

Survey of General Practitioner Income

It was reported to the General Medical Services Committee at its meeting on July 28 that the Ministry's survey of the incomes of general practitioners from National Health Service sources was complete and that the results would be in the hands of the committee within the next few days. The committee decided to hold a special meeting on Wednesday, Aug. 31, for the sole purpose of considering this report. Local medical committees are being warned that they may be asked to call meetings of their committees early in September to consider a statement on the position from the General Medical Services Committee.

SURVEY OF GENERAL PRACTICE

MEDICAL PRACTICES COMMITTEE REPORT

The Medical Practices Committee has completed its survey of the number of general practitioners practising in the various parts of England and Wales. It has listed executive council areas or parts of them in one of four schedules.

Schedule 1.—The committee considers that more doctors are needed in the places listed.

Schedule 2.—Places listed in this schedule are those, in addition to the places included in Schedule 1, open to any doctor to settle in with a view to starting practice. Admission to the medical list of the executive council concerned will be automatically granted by the Medical Practices Committee.

Schedule 3.—These are "doubtful" places. Applications to practise in them are likely to be granted, but information in the hands of the Medical Practices Committee when the doctor's application is being considered may result in the area then being closed and the refusal of his application. The establishment of a successful practice in such areas is likely to be hazardous.

Schedule 4.—These are "closed areas." The committee has decided that the number of doctors undertaking to provide general medical services in them is for the time being adequate. Closure is limited in that it gives the committee the power to refuse an application to go on the executive council list (subject to the right of the applicant to appeal to the Minister). The committee is unlikely to agree to an increase in the number of general practitioners practising in the district and might agree with an executive council to refuse to allow replacement of what might be regarded as redundant practitioners resigning from the list. But where an executive council, in agreement with the local medical committee, considers replacement desirable the Medical Practices Committee would agree. Further, it might suggest replacement in other instances where it considers it necessary. Nor does closure mean that under no other circumstances would the committee admit a practitioner to the list; personal factors advanced by the applicant or in his favour by the local executive council, the local medical committee, or other interested parties might be considered of sufficient weight to cause the application to be granted.

The four schedules are printed below:

Schedule 1

The densely populated parts of the following districts:

Counties

Bedfordshire.—Luton.

Cheshire.—Crewe and Nantwich; Hyde, Dukinfield, and Stalybridge; Runcorn and Stockton Heath; Newferry and Bebington.

Cumberland.—Cockermouth, Maryport.

Derbyshire.—Chesterfield Borough and Rural District; Ilkeston Borough; Alfreton, Bolsover, Claycross, Heanor, Long Eaton, Matlock, Ripley, Staveley, Swadlincote Urban Districts; Blackwell and Clowne Rural Districts.

Durham.—Felling Urban District; Hebburn Urban District; Jarrow Borough and Boldon Urban District; Houghton-le-Spring, Hetton, and Washington Urban Districts; Chester-le-Street Urban and Rural Districts: Stanley Urban District; Consett Urban District and Lanchester Rural District; Crook and Willington Urban District and Tow Law Urban District; Bishop Auckland, Shildon, and Spennymoor Urban Districts; Easington Rural District; Sedgefield Rural District; Stockton Urban and Rural Districts and Billingham Urban District.

Gloucester.—Kingswood.

Hampshire.—Aldershot, Eastleigh.

Hertfordshire.—Ware Urban District and Cheshunt.

Huntingdonshire.—Ramsey.

Isle of Ely.—March, Wisbech, Whittlesey.

Kent and Canterbury.—Boroughs of Bexley, Chatham, Dartford, Erith, Gravesend, Rochester; Urban Districts of Crayford, Northfleet, Sittingbourne and Milton, Swanscombe; and Rural District of Dartford.

Lancashire.—Aintree, Bacup, Barrowford, Coppull, Croston, Farnworth, Haydock, Heywood, Hindley, Huyton with Roby, Irlam, Kearsley, Leigh, Litherland, Middleton, Newton-le-Willows, Prescot, West Houghton, Widnes, Worsley.

Leicestershire and Rutland.—Ashby-de-la-Zouch, Coalville, Hinckley, Melton Mowbray excluding Somerby.

Lincolnshire.—Holland: Spalding Urban and Rural Districts. Kesteven: Grantham. Lindsey: Louth.

London.—Boroughs of Battersea, Bethnal Green, Hammersmith.

Middlesex.—Boroughs of Edmonton, Heston and Isleworth, Southall, Wood Green; and Urban District Council areas of Feltham, Hayes and Harlington, Staines.

Norfolk.—Mitford and Launditch.

Northampton.—Kettering.

Northumberland.—Ashington, Bedlington, Haltwhistle, and Wallsend.

Nottingham County and City.—Arnold, Bawtry, Beeston, Carlton and Netherfield, Clipstone, Eastwood, Hucknall, Kimberley, Langold, Stapleford, Warsop, Worksop, and the City of Nottingham.

Soke of Peterborough.—Peterborough, Whittlesey, and Market Deeping.

Somerset.—Chew Magna and Street.

Staffordshire.—Newcastle-under-Lyme Borough and Rural District; Wednesbury, Bilston, Rowley Regis, Tipton Boroughs; Kidsgrove, Biddulph, Aldridge, Brownhills, Rugeley, Darlaston, Willenhall, Wednesfield, Sedgley, Brierley Hill, Amblecote Urban Districts; Lichfield Rural District.

Surrey.—Borough of Mitcham; Urban Districts of Chertsey and Walton and Weybridge.

Sussex West.—Lancing.

Warwickshire.—Bedworth, Nuneaton, Warwick Urban Districts; Atherstone Rural District.

Wiltshire.—Swindon.

Worcestershire.—Bromsgrove, Halesowen, Oldbury, and Stourbridge.

Yorkshire.—East Riding: Haltemprice district, Hedon district, Howden and Goole. North Riding: Carlin How, Dormanstown, Grangetown, Guisborough. West Riding: Castleford Urban District and Normanton Urban District. Featherstone Urban District; Knottingley Urban District; Pontefract Borough; Osgoldcross Rural District. Horbury Urban District; Ossett Borough; Wakefield Rural District. Batley Borough; Heckmondwike Urban District. Hoyland Nether Urban District; Stocksbridge Urban District; Wortley Rural District; and Penistone Urban and Rural Districts. Hemsworth Urban and Rural Districts. Cudworth Urban District; Darton Urban District; Royston Urban District. Darnfield, Wombwell, Worsborough, Dodworth Urban Districts; Swinton, Rawmarsh, Wath-on-Dearne Urban Districts; Adwick-le-Street Urban District; Bentley with Arksey Urban District; Rotherham Rural District. Doncaster Rural District and Tickhill Urban District. Thorne Rural District. Conisborough, Mexborough, and Dearne Urban Districts. Maltby Urban District; Kiveton Park Rural District.

Denbighshire and Flintshire.—Buckley, Caergwrle, Connah's Quay, Hawarden, Holywell, and Wrexham Rural District.

Glamorganshire.—Aberdare, Bridgend, Caerphilly, Gelligaer, Llwchwr, Maesteg, Mountain Ash, Neath, Penybont, Pontypridd, Port Talbot, Rhondda.

Monmouthshire and Newport.—Abercarn, Bedwas and Machen, Bedwellty, Cwmbran, Ebbw Vale, Pontypool, Risca, and Tredegar.

County Boroughs

All of the larger cities in the country have densely populated districts, where the services of additional doctors are required. In addition more doctors are required in the following county borough areas:

Barnsley, Birkenhead, Bootle, Burton-on-Trent, Carlisle, Coventry, Derby, Dudley, East Ham, Gateshead, Great Yarmouth, Leicester, Middlesbrough, Northampton, Norwich, Rotherham, St. Helens, Smethwick, South Shields, Stoke-on-Trent, Sunderland, Tynemouth, Wakefield, Walsall, Warrington, West Bromwich, West Hartlepool, Wolverhampton.

Schedule 2

Counties

Bedfordshire.—Bedford, Dunstable, Barton and Shillington, Leighton Buzzard, Woburn, Toddington, Ampthill and Cranfield, Shefford and Arlesey, Barford, Eaton Socon, Sandy and Potton, Biggleswade.

Berkshire.—Abingdon Urban and Rural Districts; Easthampstead Rural District; Faringdon Rural District; Hungerford Rural District; Maidenhead Urban District; Wallingford Urban and Rural Districts; Wantage Urban and Rural Districts.

Buckinghamshire.—Buckingham, Winslow, Claydon, Bourne End, High Wycombe, Flackwell Heath and Marlow, Stony Stratford, Chesham, Princes Risborough, Aylesbury, Wendover, Waddesdon, Slough, Datchet, Iver, Burnham, Colnbrook, Wolverton, New Bradwell, Olney, Bletchley, Newport Pagnell, Linslade, Wing and Wraysbury.

Cambridgeshire.—Cambridge Borough and County.

Cheshire.—Lymm, Macclesfield with the exception of Bollington, Middlewich, Sale, Bromborough and Eastham, Neston and Parkgate, Bredbury and Romiley, Cheadle and Gatley, Congleton, Northwich and Winsford, Weaverham, Frodsham.

Cornwall.—Albaston, St. Blazey, Bugle, Camborne, Camelford, Carn Brea, Chacewater, St. Dennis, Helston, St. Just, Looe, Penryn, Perranporth, Probus, Redruth, Grampound, St. Austell, Bodmin, Callington, St. Columb, Launceston, Newquay, Penzance, Polperro, Porthleven, Port Isaac, Saltash, Truro.

Cumberland.—Aspatria, Brampton, Cleator, Egremont, Kirkbride, Whitehaven, Workington, Distington, Harrington, Wetheral, Wigton.

Derbyshire.—Belper Urban and Rural Districts; Dronfield, New Mills, Wirksworth Urban Districts; Chapel-en-le-Frith, Repton, Shardlow Rural Districts; Glossop Borough; Ashbourne Urban and Rural Districts.

Devon and Exeter.—Axminster, Barnstaple, Calstock and Gunnislake, Crownhill, Dartmouth, Exeter, Plymstock, South Molton, Tavistock, Tiverton.

Dorset.—Blandford, Portland, Verwood, Wimborne, Bridport, Parkstone, Poole, Sherborne.

Durham.—Blaydon Urban District and Durham City; Borough of Hartlepool; Rural District of Darlington; Urban and Rural Districts of Barnard Castle.

Essex.—Whole of County regarded "open" in absence of survey report.

Gloucester County and City.—Bitton, Bream, Chipping Sodbury, Church Down, Coleford, Drybrook, Dursley, Filton, Gloucester, Hambrook, Hugglecote, Lydbrook, Lydney, Mangotsfield, Mitcheldean, North Leach, Parkend, Stonehouse, Stroud, Tidenham, Ulney, Almondsbury, Berkeley, Blakeney, Newnham, Westbury-on-Severn, Cinderford, Chalford, Eastcombe, Frampton-on-Severn, Painswick, Pilning, Tewkesbury, Wotton-under-Edge, Warmley, Winchcomb.

Hampshire.—Gosport, Fareham, Farnborough, Havant, Basingstoke Urban and Rural Districts, Romsey and Stockbridge, Andover, Petersfield, Winchester City, Alton, Droxford, New Forest Rural District, Ringwood and Fordingbridge, Winchester.

Herefordshire.—Grosmont, Vowchurch, Bromyard, Hereford, Leominster, Ross-on-Wye.

Hertfordshire.—Royston, Baldock, Welwyn, Sawbridgeworth, Hoddesdon, Watford Borough and Rural District, Letchworth, Hitchin Urban and Rural Districts, Stevenage, Hertford, Bishop's Stortford, Tring, Berkhamsted, Hemel Hempstead Borough and Rural District, St. Albans, Harpenden, Hatfield, Elstree, Ware Rural District, Chorley Wood, Rickmansworth, Bushey, Barnet.

Huntingdonshire.—Huntingdon, Old Fletton, Somersham, Warboys, Yaxley, Kimbolton, St. Ives, St. Neots.

Isle of Ely.—Chatteris, Doddington, Ely, Haddenham, Long Sutton, Mildenhall, Parson's Drove, Peterborough, Ramsey, and Upwell.

Kent and Canterbury.—Boroughs of Beckenham and Bromley, Canterbury, Deal, Dover, Faversham, Gillingham, Maidstone with Rural District of Hollingbourne, Margate, Queenborough, Ramsgate; Urban Districts of Ashford, Chislehurst and Sidcup, Orpington, Penge, Sheerness, Tonbridge, and Whitstable; Rural Districts of Dover, Bridge Blean, Eastry, Elham, Maidstone, Malling, Strood, and Tonbridge.

Lancashire.—Accrington, Ashton-in-Makerfield, Ashton-under-Lyne, Barnoldswick, Brierfield, Chadderton, Chorley, Church, Colne, Crompton, Crosby, Dalton-in-Furness, Adlington, Anderton, Atherton, Billinge, Carnforth, Clayton le Moors, Darwen, Fleetwood, Golborne, Great Harwood, Lancaster, Lees, Littleborough, Maghull, Miln Row, Denton, Droylsden, Eccles, Ellel, Failsworth, Formby, Haslingden, Horwich, Ince in Makerfield, Kirkham, Leyland, Little Lever, Longton, Orrell, Ormskirk, Oswaldtwistle, Padiham, Poulton-le-Fylde, Prestwich, Rainford, Rawtenstall, Royton, Stretford, Tarleton, Thornton Cleveleys, Tottington, Upholland, Urmston, Walton-le-Dale, Whitefield, Whittle-le-Woods, Penwortham, Poulton with Fearnhead, Preston, Radcliffe, Rainhill, Ramsbottom, Ribchester, Rishton, Skelmersdale, Stalybridge, Standish with Langtree, Swinton and Pendlebury, Turton, Tyldesley, Ulverston, Wardle, Whitworth.

Leicestershire and Rutland.—Leicester, Loughborough Urban and Rural Districts, Lutterworth excluding Peatling Magna, Market Harborough Urban and Rural Districts excluding Hallaton, Rutland excluding Uppingham and Market Overton.

Lincolnshire.—Holland: Boston Municipal and Rural area, East Elloe Rural District with the exception of Gedney Hill. Kesteven: Stamford and Bourne, Sleaford. Lindsey: Barton-on-Humber, Keadby, Cleethorpes, Scartho, Spilsby, Horncastle, Caistor, Brigg, Scunthorpe, Barnetby, Winterton and Burton Stather, Gainsborough, Skegness, Alford.

London.—Boroughs of Bermondsey, Camberwell, Deptford, Finsbury, Fulham, Greenwich, Hackney, Islington, Lambeth, Lewisham, Poplar, St. Pancras, Shoreditch, Southwark, Stepney, Stoke Newington, Woolwich.

Middlesex.—Boroughs of Acton, Brentford and Chiswick, Ealing, Hornsey, Southgate, Tottenham, Twickenham, and Wembley; Urban District Council areas of Enfield, Friern Barnet, Harrow, Potter's Bar, Ruislip and Northwood, Sunbury-on-Thames, Uxbridge, Yiewsley, and West Drayton.

Norfolk.—Depwade, Forehoe and Henstead, Loddon, St. Faith's and Aylsham, Walsingham, East Dereham, King's Lynn, Blofield and Flegg, Docking, Downham, Erpington, Marshland, Smallburgh, Wayland, Downham Market, North Walsham, Wymondham, Thetford.

Northamptonshire.—Burton Latimer and Finedon, Corby, Daventry, Irthlinborough, Rothwell and Desborough, Rushden, Towcester, Wellingborough, Blisworth.

Northumberland.—Alnwick, Blyth, Glendale, Hexham, and Morpeth.

Nottinghamshire County and City.—Bilsthorpe, Bingham and adjacent villages, Blidworth, Costock, Huthwaite, Kegworth, Keyworth, Kirkby-in-Ashfield, Mansfield, Misterton, Newark, Pleasley, Radcliffe-on-Trent, Retford, Ruddington, Selston, Southwell and adjacent villages, Sutton-Bonnington, Sutton-in-Ashfield, West Bridgford.

Oxfordshire County and City.—Banbury, Bicester, Charlbury, Chipping Norton, Deddington, Henley-on-Thames, Little Milton, Shipton-under-Wychwood, Watlington, Whitney, and Woodstock.

Shropshire.—Chirbury, Ellesmere, Ludlow, Market Drayton, Newport, Oswestry, Shifnal, Shrewsbury, Wellington, and Wenlock.

Somersetshire.—Axbridge, Banwell, Bishops Lydeard, Bridgwater, Cannington, Cheddar, Frome, Glastonbury, Highbridge, Keynsham, Midsomer Norton, Milverton, Nether Stowey, North Curry, Paulton, Peasedown St. John, Pill, Radstock, Shepton Mallet, Stoke-under-Ham, Taunton, Templecombe, Timsbury, Watchet, Wells, West Town, Wrington, and Yeovil.

Staffordshire.—Cannock Urban and Rural Districts; Cheadle Rural District; Coseley Urban District; Leek Urban and Rural Districts; Lichfield City; Stafford Borough and Rural District; Stone Urban and Rural Districts; Tamworth Borough; Tettenhall Urban District; Tutbury Rural District; Uttoxeter Urban District.

Suffolk East.—Beccles, Botesdale, Bungay, Debenham, East Bergholt, Eye and Great Horkesley, Framlingham, Halesworth, Leiston, Lowestoft, Needham Market Stowmarket, Wickham Market, and Woodbridge.

Suffolk West.—Bury St. Edmunds, Hadleigh, Haverhill, Mildenhall, Newmarket, Sudbury, Thedwastre, and Thingoe.

Surrey.—Boroughs of Barnes, Beddington and Wallington, Godalming, Malden and Coombe, Sutton and Cheam, and Wimbledon Urban District Council areas of Carshalton, Caterham and Warlingham with Woldingham, Merton and Morden; Rural District Council areas of Bagshot and Godstone.

Sussex East.—Burgess Hill and Newhaven.

Sussex West.—Arundel, Chichester, Crawley, Emsworth, Horsham, Petworth, Shoreham, Southwick and Portslade, and West Wittering.

Warwickshire.—Arley, Coleshill, Kenilworth Urban District, Leamington Spa, Rugby Rural District Solihull Urban District, Sutton Coldfield Urban District, Tamworth Rural District.

Westmorland.—Appleby, Brough, Crosby Ravensworth, and Temple Sowerby.

Wiltshire.—Amesbury, Andover, Batheaston, Box, Bratton, Calne, Chippenham, Corsham, Cricklade, Devizes, Downton, Highworth, Ludgershall, Malmesbury, Melksham, Purton, Ramsbury, Salisbury, Stratton St. Margaret, Trowbridge, Upavon, Warminster, Westbury, Wilton, Wootton Bassett, and Wroughton.

Worcestershire.—Droitwich, Evesham, Kidderminster, Pershore, Redditch, Stourbridge-on-Severn, Tenbury, Upton-on-Severn, and Worcester.

Yorkshire.—East Riding: Beverley district, Bridlington district, Driffield district, Market Weighton, Newport, North and South Cave district, Norton, Pocklington, Scarborough, Selby, and South Holderness. North Riding: Billingham, Borough Bridge, Brotton, Brough, Catterick, Elvington, Eston and Normanby, Filey, Haxby and New Earswick, Hinderwell, Hovingham, Kirby Stephen, Malton, Marske-by-Sea, Masham, Redcar, Richmond, Ripon, Saltburn, Scarborough, Scorton, Sherburn, Skelton, Snainton, South Bank, Strensall, and Yarm. West Riding: Morley Rural District; Rothwell, Stanley, Garforth Urban Districts; Mirfield and Spenborough Urban Districts; Hebden Royd, Ripponden, Sowerby Bridge Urban Districts, and the Borough of Todmorden; Barnoldwick, Earby, and Silsden Urban Districts; Skipton Urban and Rural Districts, and the Borough of Keighley; Baildon, Bingley, and Denholme Urban Districts; Aireborough and Horsforth Urban Districts, and the Borough of Pudsey; Selby Urban District, and the Borough of Goole; Goole Rural District; Elland, [illegible]ueensbury, and Shelf Urban Districts, and the Borough of Bri[illegible]ton, Meltham, Denby Dale, Holmfirth, Colne Valley, [illegible]n Districts; Sedbergh, Settle, Bowland Rural Dist[illegible]ely Bridge and Kirkby Malzeard Rural Districts; N[illegible] Wharfedale Rural Districts.

PAYMENT OF PART-TIME CONSULTANTS

CONTRACTS WITH SEVERAL BOARDS

The Ministry of Health has sent a circular to regional boards and boards of governors giving guidance on the application of the terms of service to part-time consultants employed by two or more boards. In order to determine the consultant's total part-time remuneration it should be assumed that his services for all the boards are rendered to a single employer. Though he must hold separate contracts with each board, and may be paid separately in respect of each contract if the boards so arrange, his total remuneration should not be more than he would receive were all the time he devotes to the hospital service provided for in a single contract.

If the number of hours worked by a consultant for each board were calculated separately by each board, the number of notional half-days might be higher than if the total hours worked for all the boards were aggregated before calculating the number of notional half-days, because the translation of hours worked into notional half-days may be reckoned in the consultant's favour in arriving at a round figure.

The weighting factors added to the number of elevenths of the whole-time salary are $\frac{x}{44}$ or $\frac{11-x}{44}$, whichever gives the less result, x being the number of notional half-days. The formula should be applied not to the number of half-days worked separately for each board but to the total number of half-days worked for them all.

Each board pays the consultant in proportion to the number of hours a week he works for it.

INTEREST ON COMPENSATION

The Minister of Health has made amending regulations under which, until the amount of compensation has been notified to the claimant or his personal representative, payments in respect of interest are to be calculated and paid on a provisional basis. Underpayment or overpayment will be adjusted subsequently.

GENERAL MEDICAL SERVICES COMMITTEE

An all-day meeting of the General Medical Services Committee was held on July 28, Dr. S. Wand presiding. The committee congratulated Dr. E. A. Gregg on his election to the chairmanship of Council, and again expressed appreciation of his long term of service in the chair of the committee.

On the constitution of the committee an objection from Cumberland to the proposed grouping of electoral areas was considered. Cumberland asked that, with North Westmorland and Carlisle, it might form a special area instead of being joined with Northumberland and Durham. The committee was of opinion, however, that the proposed arrangement could not be altered without upsetting the balance of representation, and trusted that with good will the two seats would be filled with as much satisfaction as possible to all parts of this rather unwieldy northern area.

Remuneration

It was reported that the statement from the Ministry on remuneration following its inquiry into the incomes of general practitioners from National Health Service sources was expected very shortly. It was agreed that it should be circulated immediately to members of the committee and that a special meeting be called to consider it on Aug. 31.

Arbitration

Following negotiations between the Joint Committee of Consultants and the Ministry of Health, the statement on what had been agreed on arbitration was reported to the committee—namely, that no changes would be made in terms and conditions of service without discussion in the appropriate Whitley machinery, that remuneration was a subject suitable for arbitration, and that, save in exceptional circumstances and after "Whitley" had been exhausted, issues of remuneration remaining in dispute would go either to arbitration or for inquiry and report by a committee.

The view of the General Medical Services Committee was that this went a considerable way to meet the necessities of the position, and it was agreed to see how it worked out before taking any action on the resolution of the Annual Representative Meeting insisting that arbitration machinery be set up and that the necessary alteration be made in the Amending Bill.

The chairman of the committee was asked to write to Sir Lionel Whitby, chairman of the Joint Committee of Consultants, thanking him for the great force and skill with which he had handled the negotiations with the Ministry on the terms and conditions of service for consultants and specialists—negotiations which, as on the issue just mentioned, had their repercussions on the general practitioner side.

Midwifery Service

The committee considered at some length a statement (reproduced below) on the domiciliary midwifery service forwarded by the Ministry of Health from the Central Health Services Council. Many members of the committee took strong exception to certain of the statements in the document, which it was felt would tend to diminish the status of the general practitioner in the maternity service, and it was agreed to urge the Ministry that nothing should be done pending a conference of interested bodies which has been called for Sept. 28.

A further report of the committee's discussions will appear in a subsequent issue of the *Supplement*.

DOMICILIARY MIDWIFERY SERVICE

The Ministry of Health has issued to local health authorities and local executive councils the following statement on Domiciliary Midwifery Services, which was prepared by the Standing Maternity and Midwifery Advisory Committee of the Central Health Services Council:

Misunderstanding exists about the nature of the medical services available for the expectant mother who is to be confined in her own home. In certain areas the terms of service of the doctor providing maternity medical services have been correctly interpreted and the service is working smoothly, but in others difficulties have been encountered.

The principal cause of the trouble is the widespread belief among general practitioners and the public that the agreement between a doctor and a patient by which the doctor undertakes to provide maternity medical services as laid down in the terms of service converts the case into what is commonly known as a "doctor's case," that is the doctor accepts full responsibility for the antenatal care, for the labour, and for the lying-in period. This was certainly not the intention: it was not intended in any way to diminish the importance of either the antenatal clinics or the midwives by the introduction of the maternity medical services.

In the past, about three-quarters of the domiciliary confinements were conducted by midwives who were booked early in the pregnancy. The antenatal care was primarily the responsibility of the midwife, who in most cases worked in close association with an antenatal clinic. The medical officer in charge of the clinic could accept no responsibility if an abnormality arose, and the midwife had therefore to call in a general practitioner who had not previously seen the patient. This has long been recognized as unsatisfactory, and the maternity medical services were designed to get over this difficulty. At the same time it should be appreciated that a good service was being provided before July 5, 1948: the progressive reduction in the maternal mortality and stillbirth rates bears witness to this fact.

If the best possible maternity service is to be provided under the National Health Service the general practitioner, the

midwife, the antenatal clinic, and the pathologist, as well as the hospital and specialist services, all have a part to play as members of a team.

The midwife and the antenatal clinic have at their disposal all the services of the local health authority. If the patient fails to attend as advised she is visited without delay. Blood examinations are carried out as a routine and instruction given in hygiene and mothercraft. If any abnormality arises the general practitioner will be informed.

For the payment of a comprehensive fee a general practitioner providing maternity medical services undertakes:

1. To examine the patient at the time of booking.
2. To examine the patient at about the 36th week.
3. To make a post-natal examination about six weeks after confinement.
4. To provide any medical attention additional to the above either if he considers it necessary, or in response to a call from the midwife.

He is not required to undertake the more frequent routine antenatal supervision that is essential, nor to attend the labour, unless such attendance is considered necessary by himself or by the midwife. The doctor may, of course, provide additional services if he so desires. His remuneration is not affected whether or not he gives such additional services.

By the rules of the Central Midwives Board the midwife must undertake regular antenatal supervision even if this duplicates the examination of the general practitioner, unless the doctor makes it quite clear that he accepts full personal responsibility for the case during pregnancy, labour, and lying-in period. The general practitioner may of course assume these full responsibilities if he considers it necessary. But it is the hope of the Minister that in domiciliary midwifery the midwife will continue to be regarded as the normal attendant, supported by the antenatal clinic during the pregnancy, and working in co-operation with the general practitioner who has had the opportunity to satisfy himself that there are no deviations from the normal in the patient's general health during pregnancy nor obstetric complications towards the end of pregnancy and will come to her aid if trouble arises during labour or the lying-in period. The midwife will consider herself to be acting as a practising midwife unless she has been informed to the contrary by the doctor. The success of this arrangement will depend on the close co-operation and understanding between the general-practitioner obstetrician and the midwife.

The arrangements for the introduction of a maternity medical service under the National Health Service were meant to be an addition to—not a substitute for—the facilities previously available for the care of the expectant and nursing mother. There has unfortunately been some misunderstanding about this in some parts of the country, but it is hoped that this statement will help to clarify the position as the services gradually settle down.

3,000,000 WAIT FOR SPECTACLES

The current "News-Letter" of the Association of Optical Practitioners announces that orders for well over 3,000,000 pairs of spectacles are outstanding under the National Health Service.

REMUNERATION OF NURSES

BAN ON HIGHER PAY

The Ministry of Health has sent a circular to hospitals in the Service saying that "considerable numbers of nurses have hitherto been employed by hospital authorities at rates of remuneration and under conditions of service which do not accord with the recommendations of the Rushcliffe Committee; this has been notably the case where nurses have been employed through the agency of nursing co-operations and similar organizations which themselves fix fees and charge commissions." The circular points out that nurses in the Service must be paid in accordance with the rates agreed by the Whitley Council, and that arrangements for nurses not being paid in accordance with the agreed rates must be ended as soon as possible.

In some cases the nurses referred to have been paid at higher rates than those recommended by the Rushcliffe Committee.

PAY OF FORCES M.O.s

No progress has yet been made in the negotiations with the Ministry of Defence on remuneration. A preliminary meeting was held in May, at which representatives of the Ministry of Defence and the Service Departments inquired how the Association's proposals had been calculated. Some correspondence followed, but no further negotiations. It is understood that the Association's proposals are under consideration "at a high level."

HOSPITAL FINANCE

COST ACCOUNTS

The Ministry of Health has informed hospitals that a standard form of cost account will be introduced as soon as practicable. For the period ending March 31, 1949, accounts will be analysed in accordance with Tables B and D in the Third Schedule of the Hospital Accounts and Finance Provisions Regulations, which require details of how money is spent and received. Further statistical data asked for include the number of in-patient days and out-patient attendances, as well as a list of special departments at the hospital, with information about the number of specimens examined, etc.

The Minister asks hospitals which prepared detail cost accounts before the appointed day to send a summary showing the average figures for the period to March, 1949.

HEALTH SERVICE COSTS IN LONDON

The London Executive Council announces that payments for the Health Service during the first year amounted to £8,648,185, and that administration cost 1·25% of the total. The figures are as follows: Medical services, £2,627,614; dental, £2,300,532; ophthalmic, £1,693,767; pharmaceutical, £1,918,188; administration, £108,084.

HOSPITAL SERVICES

COMMITTEE TO REVIEW

The Ministry of Health states that the Central Health Services Council has appointed the following committee to review the organization of the hospital services under the National Health Service Act: Mr. F. Messer (chairman), Sir Harold Wernher (vice-chairman), Mr. E. C. F. Bird, Alderman Bradbeer, Mr. F. J. Cable, Sir Allen Daley, Mr. S. C. Fryers, Mr. A. J. P. Howard, M.P., Mr. R. A. Mickelwright, Sir Owen Morshead, and Dr. W. G. Patterson. Joint secretaries are Mr. E. J. S. Clarke and Mr. E. W. Bryant, of the Ministry of Health.

The committee will not consider the administration of individual hospitals but will make recommendations and frame detailed terms of reference for a committee on the subject.

RETURN TO PRACTICE

The Central Medical War Committee announces that Dr. A. W. J. Houghton, M.R.C.P., Wren Cottage, Pulverbatch, near Shrewsbury (Tel.: Dorrington 24), has resumed civilian practice. (*Corrected announcement.*)

Correspondence

Grading of Hospital Staff

SIR,—In view of the discrepancies appearing in the present grading of specialists, due largely to the fact that there are no criteria laid down to define a specialist or a hospital medical officer, the St. Helier Group Medical Advisory Committee have instructed me to send you a copy of the criteria they laid down to help the assessing committees working in this group.

This grading is dependent to a certain extent on whether a person engaged in general practice is debarred from full specialist status, but we are concerned primarily in preventing people who by any reasonable standards qualify for specialist status being reduced to hospital medical officers. To say that hospital medical officers are in fact specialists is nonsense and is in line with the political trickery with which we are becoming familiar.

It is felt most strongly that some classification on these lines should be drawn up, approved, and accepted to guard us not only from the Minister and his satellites but even, unfortunately, from some of our own colleagues.

CRITERIA FOR CLASSIFICATION

In our opinion a specialist should be defined as a medical practitioner who

(i) has held an appropriate higher qualification for five or more years ;

(ii) has had training and experience in his specialty ;

(iii) is capable of practising his specialty without supervision ;

(iv) has held a hospital staff appointment prior to July 5, 1948 ;

(v) is recognized by his colleagues, in his district, as a specialist.

In considering the senior medical staff of our hospitals we find that they are divisible into three main groups.

Group 1.—Those who are entirely engaged in specialist practice, hold an appropriate higher qualification, and have a hospital appointment as a specialist should without question be recognized automatically as of full specialist status.

Group 2.—Those not entirely engaged in specialist practice but holding an appropriate higher qualification and a specialist hospital appointment and recognized by their colleagues in the district as specialists should also have full specialist status.

Group 3.—(*a*) Those who hold a hospital appointment as a specialist though not holding an appropriate higher qualification should, by reason of their experience, be retained as senior hospital medical officers. (*b*) In exceptional cases practitioners with a specialist hospital appointment of many years' standing and recognized by their colleagues in the district as specialists, but not holding a higher qualification, should be considered for full specialist status.

—I am, etc.,

P. M. KELLY,
Hon. Sec., St. Helier Group Medical Advisory Committee.

SIR,—I am in agreement with the views expressed in your leading article (July 23, p. 220) concerning the grading of specialists. I should like to point out, however, a slight error in your description of men of registrar status—at any rate, so far as this region is concerned.

The vast majority of senior registrars in this region have been qualified for fourteen or fifteen years and not for four or five as you suggest. Perhaps the senior registrars here have been very slow in achieving specialist status, but I cannot really believe that this is true only of this area.—I am, etc.,

Sheffield. W. INGMAN.

SIR,—In your controversial leader on the grading of specialists (*Journal*, July 23, p. 220) you suggest that there is a case for the grade of S.H.M.O. in tuberculosis sanatoria. Apart from the fact that your suggestion comes at a most unfortunate time, while the regrading of specialists is still proceeding, there are other serious objections to it.

Modern sanatorium work demands a high degree of special experience and skill. You appear to suggest that men who have taken considerable time and trouble to acquire these qualities should be rewarded by a low degree of remuneration and professional standing.

Furthermore, for reasons well known to all, tuberculosis is one of the major medical problems in this country to-day. Good men are needed to tackle it, and they will not be attracted by the lure of an inferior status.

Sanatoria should be medically staffed by full specialists and trainee specialists. Our tuberculous patients deserve no less. —I am, etc.,

Worcester. R. B. MAYFIELD.

SIR,—Having recently been accepted, albeit apparently only upon reluctant second thoughts, as of "full specialist status" and finding my foot thus poised, however insecurely, upon the lowest step of the New Citadel, I may perhaps with less rancour comment upon the activities of those elderly medical gentlemen who have allowed themselves to be used to belittle the ability of their colleagues.

Some form of grading is of course necessary, but this was achieved in the Services with much more consideration and with much less bizarre results. When one knows that among those whose competence is now disparaged are not only many who have practised their specialty with success for more than ten years but also one who was, during the war, an adviser to the Air Ministry, one wonders whether our arbiters may expose themselves not only to obloquy but even to a claim of damages for defamation.

Whether their motive be the well-established principle, "It took me years to get anywhere and I'll make it tough for you," or the hope of favour for assiduous devotion to the course politic, it would appear to many of us that the apparent misuse of their professional authority by these elderly gentlemen in proscribing their colleagues would be a fit subject for review by the General Medical Council.—I am, etc.,

St. Day, Cornwall. CHRISTOPHER HEATH.

SIR,—May I congratulate "Qualified Consultant" (*Supplement*, July 16, p. 50) on his courageous and lucid writing and carry at the same time his suggestion a step farther to its logical conclusion by putting forward some concrete proposals ?

The confusion and secrecy that enshroud the grading of specialists is a clear indication by itself that something is fundamentally wrong with the whole problem. For example, speeches made by representatives at Harrogate and correspondents in your columns suggest that grading committees have acted on instructions from some quarters. Yet I am informed by the highest authority that the Joint Committee "could not lay the blame at the door of the Ministry, in that the latter promptly retort that the grading, having been carried out by the profession itself, is no concern of theirs." And in a letter dated July 7, 1949, one of the assistant secretaries of the B.M.A. assured me that "we are informed authoritatively that the grading committees have not received instructions from the Ministry with regard to the number of practitioners who hold contracts with the regional board who should be graded senior hospital medical officers. I am quite sure that grading committees would not have carried out such instructions." What is the truth ?

We all agree with "Qualified Consultant" that "we are now at the last ditch, and if we do not fight now we will never get the opportunity again in our lifetime," but who is going to organize this fight ?

The Central Consultants and Specialists Committee and the Joint Committee in negotiating with the Minister can only safeguard principles regarding terms and conditions of service and remuneration, but obviously they have neither the power nor the interest to enforce their just and fair application in practice. Indeed, a situation has arisen which is exactly the same as if a trade union had concluded after a hard fight a successful wage agreement in principle for their skilled labourer members and had *then* allowed in practice a large proportion of their members to be classified arbitrarily as *unskilled* labourers, and supported the *employers* to pay them at *unskilled* rates. Such a situation would be the more absurd

should it ever occur in that the so-called "unskilled labourers" could seek legal redress from a competent court, while highly specialized members of the medical profession cannot.

To clarify the position I wish to put through the medium of the *Journal* the following questions to the B.M.A. :

(1) Would the B.M.A. organize without delay a campaign—in the same way as they did for the general practitioners and for the consultants and specialists in principle—for the consultants and specialists in practice, to ensure justice and fair play in grading ?

(2) If so, would the B.M.A. form a representative committee to investigate the *modus operandi* of the grading and appeal committees ?

(3) And if so, would this committee form a subcommittee to collect relevant material such as copies of appeals and other evidence, so that they may have a nation-wide view of the magnitude of the problem ?

(4) Would the B.M.A. lift the veil of secrecy over the whole procedure of grading by publishing at once all available facts at their disposal, such as the composition of the grading committees, their terms of reference, the methods, standards, and principles which they had applied to grading, and above all whether the grading committees did or did not receive instructions from the Ministry, or the regional boards, or from any other body as to the proportion of practitioners who were to be graded other than consultants ?

—I am, etc.,

QUOUSQUE TANDEM ?

B.M.A. War Memorial

SIR,—At the recent A.R.M. the balance of the argument about the proposed war memorial was, from the voting, clearly in favour of some physical visible memorial, and we were convinced the educational project was not so attractive as many of us had presumed. There was, however, a strong feeling against the proposal of a fountain as the form a memorial should take, and this from several angles which I need not detail. The purpose of this letter is to suggest in all humility a form of memorial which would, I believe, prove acceptable to the majority of our members, and in this project the greatest possible unanimity is most desirable.

If the memorial is to be satisfactory it must be one which should suggest, and if possible promote, the highest ideals of medicine, in the service of which those who fell gave their lives. At the same time it should not be purely utilitarian or suggest that the B.M.A. was trying to complete B.M.A. House "on the cheap." A war memorial at Trinity College, Cambridge, which some of those who attended last year's Annual Meeting may have seen, gives an idea of one way in which these requirements might be met.

The memorial referred to is the Junior Combination Room at Trinity College, which was redecorated by Mrs. Allhusen in 1925 in memory of her son and husband. This room is quite outstanding for its beauty amid the architectural glories of Cambridge. There is in it nothing extravagant or exotic, yet it is impossible for anyone to enter it without saying to himself, "This room is something special. What is it for and why was it made ?" There is about it an atmosphere of quiet grace and beauty, a dignity that is neither heavy, dull, nor dowdy, that strikes even the least responsive.

Now this surely was the aim and probably also the effect of the Greek temples of healing. It is the spirit which is so largely missing in modern life and even in modern medicine, a spiritual quality the lack of which lies at the root of many of our present ills, social as well as medical. My proposal therefore is that one of the rooms at B.M.A. House—perhaps the old library would be suitable, and the fact that to use it would entail some sacrifice should be no real obstacle—should be transformed into such a quiet haven of restfulness, a refuge from the bustle of life in London (and B.M.A. House, too), not definitely a reading-room nor a smoking-room, which are provided elsewhere, but a place of beauty and refreshment which might perhaps be used for very special receptions, etc.

It was stressed by several speakers that our memorial ought to be one that visitors to London would be anxious to see, and I should imagine that our finest designers would be proud to design a room which would preserve the highest traditions of the past for the enrichment of the future, a memorial that would mellow instead of grow old, a room in which fine flowers, etc., would keep evergreen the memory of those who gave their lives that we might not only live but live in peace and freedom.

It seems to me that this sort of a memorial, which I have so poorly tried to outline, would be of particular interest to our members overseas, as it would give an opportunity for the various Branches to enrich the adornment of the room by gifts of special products of their countries—e.g., carpets from India, rare woods from the Tropics, perhaps even a golden memorial tablet from South Africa—while I think our many friends in the U.S.A. would like to join with an expression of their comradeship and unbounded generosity. The design would, of course, have to provide for these things so that all would take their place in building up a harmonious whole, as diverse in its parts as medicine, our Empire, and the war itself, yet expressing, as they do, one spirit.

I am confident that such a memorial would be sought out by visitors from overseas, who would look with pride for the special contribution of their country, and as one who has attended many meetings at B.M.A. House I am sure that those who go there might find that the memorial room was not only a thing of beauty and a joy for ever but a perpetual refreshment of the spirit, an invitation to that quiet and reflection which are essential to real health and healing, a gracious reminder of things which, though unseen, are eternal. By it not only would B.M.A. House be enriched and beautified but the standards of medicine (and of civilization) be upheld, as those who gave their lives for it would have wished.—I am, etc.,

Winsford, Cheshire. W. N. LEAK.

Headquarters and the Regions

SIR,—My attention has been drawn to remarks made by Dr. W. Hunter at a recent Conference of Honorary Secretaries of Divisions and Branches (*Supplement*, May 28, p. 297).

In referring to the method now in operation for making available to the regions the services of the Headquarters secretarial staff, as explained by the Secretary, Dr. Charles Hill, Dr. Hunter expressed his fear that the policy of "regionalization" might overweight the administrative machinery of the Association, and proceeded to say : "We want not a man from Headquarters to keep an eye on the periphery. . . ." These are entirely wrong assumptions. I take it the object is to enlighten members of Branches on many points of doubt and difficulty that are constantly arising.

Dr. Hunter must not say : "We are self-sufficient here in the North ; do not disturb us." Rather should it be suggested that the Branch hold quarterly meetings to which a member of the Headquarters staff would be invited to attend.—I am, etc.,

Hetton-le-Hole, Co. Durham. R. MACLEOD

POINTS FROM LETTERS

Tuberculosis Service

ASSISTANT T.O. writes: The propounding of major principles was not a function of the Spens Committee. Only incidentally was anything approaching principles laid down. Amongst these were that: (1) A specialist is a specialist. (2) To ensure the manning of all special departments in all hospitals all specialists shall be paid on the same scale, and/or with equal eligibility for promotion to super-scales. (3) The prefix "assistant" need not, and frequently does not, imply intrinsic inferiority. Against expectation the tuberculosis service has been included in the hospital service. There can be no honest doubt that had this been foreseen tuberculosis would have been included with radiology, dermatology, clinical pathology, etc., in the list of specialties in the Spens Report. T.O.s who have been graded as senior hospital medical officers have a real grievance. Some, like myself, have been graded as *junior* medical officers. . . .

Conservative Policy

Dr. J. P. O'SHEA (Newquay, Cornwall) writes: On p. 46 of *The Right Road for Britain* the Conservative Party promises (*a*) appeal to the courts over the Minister, (*b*) free drugs for the private patient, thereby putting right social injustices. If any medical men have any spare time, they can surely see wherein their duty lies these coming weeks.

Association Notices

B.M.A. LECTURES

Every Branch and Division may have one B.M.A. Lecture a year. The lecturer, who is chosen by the Branch or Division, is an authority on his particular subject. He is invited from the Central Office and receives an honorarium and his expenses. Branch and Divisional secretaries making up their programmes for the forthcoming year are invited to send requests to Headquarters for B.M.A. lectures. The application should be on a special form obtainable from Headquarters denoting the name of the lecturer, the subject, and choice of dates.

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1949. The prize will be awarded at the Annual General Meeting of the Association to be held in 1950.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Preliminary notice of entry for this competition is required, on a form to be obtained from the Secretary.

8. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

9. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

10. Inquiries relative to the prize should be addressed to the Secretary.

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1950. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff or senior hospital medical officer of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1950 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

The title of the proposed essay and the motto should also be notified in writing to the Secretary by Dec. 1, 1949, on a form to be obtained from the Secretary. Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1950. The prize will be awarded at the Annual Meeting of the Association to be held in 1950. Inquiries relative to the prize should be addressed to the Secretary.

PRIZES FOR MEDICAL STUDENTS, 1950

The Council of the British Medical Association is prepared to consider the award in 1950 of prizes to medical students for essays submitted in open competition.

The subject of the essays shall be "Clinical Teaching in Relation to the Practice of Medicine."

The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for a prize.

If any question arises in reference as to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. In determining the number and the value of the prizes to be awarded the Council will take into consideration the number of essays received. Should the Council decide that no essay entered is of sufficient merit, no awards will be made.

Each essay must be typewritten or legibly written in the English language, on one side of the paper only, must be unsigned, and must be accompanied by a form of application which can be obtained from the undersigned. Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than Dec. 31, 1949. Inquiries relative to the prizes should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

CHARLES HILL,
Secretary.

Meetings of Branches and Divisions

LEEDS DIVISION

The Leeds Division has expressed its pleasure on hearing that Dr. J. E. Rusby, immediate past-chairman of the Division, and Dr. J. Wyllie have been appointed to the Commission of the Peace.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

THOMAS ADDISON: PIONEER OF ENDOCRINOLOGY*

BY

Sir HENRY DALE, O.M., G.B.E., F.R.C.P., F.R.S.

Thomas Addison was second in that matchless succession of physicians and morbid anatomists—Richard Bright, Thomas Addison, William Gull, and Samuel Wilks—whose work at Guy's Hospital in the earlier and middle years of the nineteenth century raised to such heights the reputation of this school as a great centre of medical teaching and investigation, and contributed so much to the foundation of the great nineteenth-century tradition of advancing medical knowledge by the accurate study and differentiation of diseases in the clinic, closely linked with an equally thorough scrutiny of their results as seen after death. The names of two of them, Bright and Addison, have been permanently associated with diseases which they thus described; the number would be three if we included the name of Thomas Hodgkin, who was curator of the museum here in the same period, though never on the clinical staff. Two of them again, Addison and Gull, can be regarded as clinical pioneers of endocrinology. In Gull's case we ought to associate his achievement with that of another and younger Guy's physician, Hilton Fagge, whose recognition of absence of the thyroid as the cause of cretinism enabled Gull, in 1874, in describing "a cretinoid condition in adult women" now known as myxoedema, to associate it with atrophy and functional defect of that gland. That, however, was a quarter of a century later than Addison's first mention of a condition which he had discovered, now known everywhere as Addison's disease, and which he then described as "a remarkable form of anaemia" regularly associated with disease of the suprarenal capsules.

Reproduced by kind permission of the Royal Society of Medicine.

Two Pioneer Communications

The late Sir William Hale-White,† whose long life enabled him to transmit to more than one later generation the great tradition of this school from a time when Addison was still held in living memory here, has suggested that "the whole of endocrinology dates from March 15, 1849"—this being the date on which Addison made the first, short communication on his disease to the South London Medical Society. I believe that a good case could be made for that claim. There had, indeed, been earlier accounts of diseases—diabetes mellitus and exophthalmic goitre—which were shown much later to have a causal relationship to endocrine disorders. Even cortical tumours of the suprarenals had been recorded early in the nineteenth century, and hirsutism noted in a girl patient, but again without clear recognition of an aetiological relationship. I think, therefore, that we may agree with Sir William Hale-White that

*The Addison Lecture given at Guy's Hospital on June 23.

†*Great Doctors of the Nineteenth Century*. Sir W. Hale-White. Arnold and Co. 1935. To those who wish to learn more of Addison's life, personality, and achievements, the chapter on him in that volume is recommended. It gives references to other accounts of him by Samuel Wilks, who was his pupil, and Lonsdale, a lifelong medical friend.

endocrinology began effectively with Addison's paper, which in 1849 made the first clear attribution of a general morbid condition to defect of a ductless gland; and you will note that the date gives a centenary character to our celebration of this great man and his achievement.

Addison's fuller account of the disease which now bears his name was published six years later, in 1855, as a separate slender quarto with fewer than 46 pages of large printed text, richly illustrated with coloured lithographic plates and bearing the title *On the Constitutional and Local Effects of Diseases of the Suprarenal Capsules*. You will note that even the title emphasizes the aetiological inference. On these two pioneer communications by Addison the author of a recent textbook on the now enormous science of endocrinology makes apt comment: "... They show how much can be accomplished, without any of the modern clinical and laboratory facilities, by keen observation of the living and dead patient. They are prominent examples of concise and descriptive medical writing." They are so indeed; no better model could be recommended to the many who to-day seek to give permanent record to observations which are, in the main, of slighter significance.

A remarkable feature of the publication of 1855 is that, by way of introduction to the principal theme, Addison describes and differentiates another new disease, for which, by contrast, he had failed to discover an adequate cause by examination post mortem. This he named "idiopathic anaemia," but it is now generally known as "pernicious" or "Addison's" anaemia. It is not clear that he had at first distinguished with certainty between these two fatal diseases, in both of which anaemia and lassitude were prominent; but there is no doubt about the distinction in the book of 1855. His object there was to give an exact account, based on a series of cases, of what he called "bronzed skin" or "melasma suprarenale," known to us as "Addison's disease." The description of "idiopathic anaemia" is given only by way of introduction, to explain that the author was looking for additional cases of this condition when, in his own phrase, he "stumbled upon" another major discovery, which is the main subject of the book.

So that this slender volume contains the first full description of two new diseases; and, to quote Sir William Hale-White again, "Addison's account of each is so perfect that nothing has been found wrong in his clinical picture, and nothing has been added except facts that have been obtained by instruments which he did not possess, and a few occasional symptoms not present in the cases which he describes." I think it should be added that, if Addison had looked at the marrow in the long bones of the patients dying of pernicious anaemia, his acute eye could hardly have missed its unusual appearance. Even without any of the technical equipment which has made haematology a later possibility, he might in this case also have associated what he could see post mortem with the general disease. He certainly could not have foreseen, however, that the bone-marrow defect and the consequent anaemia would be traced many years later, in 1926, to the failure of a kind of endocrine control normally exercised by the liver; and even remoter from any conception possible to Addison, or to anybody till very recent years, is the news from two different research centres, in America and this country, of the isolation this year of the immensely active agent responsible for this endocrine control of the haematopoietic function, and the remarkable discovery that cobalt is an important element of its composition. Perhaps we may regard that, too, as an achievement suitably commemorating the fact that pernicious anaemia, which this potent hormone (or vitamin) so dramatically relieves, was first recognized by Addison about 100 years ago.

Other Achievements

When Addison's book describing these diseases was published in 1855 he was already 60 years of age. It would be very remarkable if he had first begun to make and to publish discoveries of such outstanding merit so late in life. In fact, he had already made and published others in an impressive series; and some of these, in particular those dealing with pneumonia and phthisis, were regarded by his pupil Wilks as the highest of all his achievements. What is really remarkable is that they should have been so little recognized and so widely forgotten. His earliest publication of importance was a characteristically perfect description of the clinical appearance which he found to be associated with, and diagnostic of, a fatty liver. Then in 1839, when he was 44 years old, in a book, *Elements of the Practice of Medicine*, which he published with his senior, Richard Bright, Addison gave the first descriptions of appendicitis and its consequences—"descriptions," according to a modern writer, "so clear and well presented that they could not be surpassed to-day." Later he gave the first correct account of the pathological process of lobar pneumonia; he published observations calling for a profound modification of the earlier conception, due to Laennec, of the destructive process in pulmonary phthisis; and he discovered and described xanthoma, which he called "vitiligoidea." And all these contributions to the advancement of medical knowledge, any one of which might be judged adequate by itself to have given him high rank as an investigator, were made by Addison before he discovered the two diseases which bear his name and thereby keep it in general remembrance among those who study and practise medicine.

When Addison came to London after graduation in Edinburgh, he gave his time and interest for some years chiefly to diseases of the skin. This interest he retained after he had begun his career at Guy's, where he entered as a student in 1817; it was he who later superintended the making of the beautiful wax models of skin conditions which are still one of the great treasures of the pathological museum here. He seems to have been rather a proud and shy man, not easy of approach; but none of the Guy's men in that great succession stood higher in reputation with his colleagues and pupils as a physician or as a teacher. Much of his time was spent, and practically the whole of his professional interest was centred, in this hospital. Outside it he sought no recognition, and he received but little. Only late in his career was he elected to the Fellowship of the Royal College of Physicians, and he held neither lectureship nor office there. He was never even proposed for the Fellowship of the Royal Society, and he was never a physician to the Court. Here you will keep him in proud memory as the greatest of all, perhaps, of the great medical investigators and teachers who were members of the staff of this hospital in that period. As his pupil, Samuel Wilks, wrote of him: "For many years he was the leading light of Guy's, so that every Guy's man during the thirty or forty years of his teaching was a disciple of Addison, holding his name in the greatest reverence, and regarding his authority as the best guide in the practice of his profession."

The Development of Endocrinology

In the medical circles of a wider world Addison will be remembered chiefly as a pioneer of the science of endocrinology—as the man who first entered and opened to other explorers a new territory which in the intervening century has been extended in all directions and brought under a most vigorous cultivation. There have been periods in which doubts of its further fertility have become prevalent and have seemed even to be natural, but it is to-day yielding harvests of medical knowledge in overwhelming abundance and in bewildering variety. I am going to invite you now to follow me in a preliminary survey, at the best a most cursory review, of the lines of development along which the present position has been reached. Then I shall endeavour to speak in somewhat greater detail of the course of the advance, including some recent and intricate phases, of knowledge of the endocrine functions of the particular ductless glands, the suprarenals, which, through Addison's discovery, provided endocrinology with the point of its very beginning, and which are now providing a focus for some of its most recent and most rapidly progressive developments.

I think we may assume that, brilliant and accurate observer as he was, Addison went as far as it would ever have been possible to proceed with the advancement of knowledge of an endocrine defect by simple observation of the results of a natural process at the bedside and in the post-mortem room. His work came at the end of the purely observational period and at the beginning of a new epoch, in which deliberate experiment was to play a dominant part. It is curious, indeed, that the use of the experimental method in medicine should have fallen so long into abeyance. William Harvey had shown what it could do, and had particularly enjoined its use on his fellow physicians, two centuries earlier; but before Addison's day English physicians appear to have forgotten Harvey's injunction, and to have left the use of experiment to surgeons like John Hunter and Charles Bell. And when a major revival of the experimental method came, opening the era in which we are still living, it began, not in Harvey's England, but on the European continent.

There, in Paris, the founder of modern physiology, Claude Bernard, in his experimental studies of the glycogenic function of the liver had reached and propounded the general idea of an internal secretion into the blood. The idea was not an entirely new one; its germ can be found in medical writings at least as early as 1775; but Bernard gave it form and an experimental basis. He was not directly concerned, however, with the specifically acting internal secretions of the glands with which endocrinology normally deals; and, apart from what had been known since prehistoric times of the effects of castration, the first attempt to study the function of an endocrine organ by deliberate experiment must apparently be credited to Brown-Séquard, who began to remove suprarenal glands from animals by operation in 1856, the year after Addison's book was published. His animals all died rapidly; but any significance which his results might otherwise have claimed seems to be called in question by his frequent record of fatality following unilateral adrenalectomy—an operation which later workers, using a clean surgical technique, have uniformly found harmless. In any case, neither he nor Tizzoni (1886), nor Abelous and Langlois (1891), who thus later confirmed the fatal effect of double adrenalectomy, contributed much more than a confirmation of Addison's conclusion, from his study of Nature's experiments, that the function of the suprarenals was for some reason a vital necessity.

It was in 1856, again, that Moritz Schiff reported that extirpation of the thyroid gland was fatal to dogs—many years, it will be realized, before the clinical studies of Fagge and Gull brought to light the connexion between defect of thyroid function and cretinism or myxoedema. There can be no doubt, however, that the effect which Schiff thus early observed was mainly due to his removal of the parathyroid glands with the thyroid, to which in the dog they are closely attached. This was eventually made clear by the work of Gley in 1891; but, before this, Schiff had himself shown that successful grafting of a portion of a dog's thyroid gland, which presumably contained a parathyroid, would protect it from the normally fatal result of removing the remainder. And after Gley's demonstration of the separate function of the parathyroid glands the possibility and protective effect of grafting these alone was shown by von Eiselsberg (1892), Leischner (1909), and others.

Meanwhile the experience of Reverdin and of Kocher on the myxoedematous or cachexial condition following surgical removal of the human thyroid for goitre, and Horsley's production in 1884 of an artificial myxoedema by thyroidectomy in the monkey, had brought the experimental work on the thyroid again into closer relation with the observed results of its atrophy in man. And then in 1891 came the first successful application of these experimental findings in practical therapeutics, when Murray, of Newcastle, showed that myxoedema could be successfully treated by administering an extract of sheep's thyroid—a notable milestone, indeed, on the road of advance in endocrinology. In this case, at least, the formation of an internal secretion was no longer a matter of inference: it had become a demonstrated fact.

This advance was followed, however, by a long and discouraging delay, which was especially obvious on the side of remedial application. When I myself, as a student, first began to be conscious of physiology and its progress, Horsley's experimental results and Murray's triumphant application of them were still relative novelties, and there was great interest in the likelihood of analogous therapeutic success in diseases due to defects of other ductless glands. As the years went by, however, such possibilities seemed to become increasingly remote. Plenty of observers were trying to correct such defects, whether resulting from disease or from experimental removal, by administering glands in substance or as artificial extracts; but no convincing success was for many years obtained in such other cases—neither with the parathyroid and suprarenal glands, nor with the gonads, nor with the pancreas, the removal of the latter having been found by Minkowski, in 1889, to cause a diabetes mellitus. With all these glands, on the other hand, protection against the effects of removal was obtainable by the establishment of successful grafts in advance.

It began to be believed, and the conviction grew and hardened with time, that the thyroid might be unique among these presumptively endocrine organs in the stability of its active principle, or in the extent to which this was stored in the gland so as to be available at a given moment for extraction. It had not, indeed, been established even yet, by strict evidence, that these other organs had in fact an endocrine function: one or another of them, if not all, might conceivably act by destroying an injurious by-product rather than by supplying a factor necessary for normal metabolism. And while this position of doubt remained, the progress of endocrinology, especially on the side of remedial replacement, was of necessity halted. Thus there grew, for a time, a discouraging tendency to suspect that the experimental method, like that of clinical observation

before it, might be approaching the limits of what it could achieve in this difficult field of inquiry. Then, after some thirty years, came the discovery of insulin by Banting and Best in 1921, revolutionizing the treatment of pancreatic diabetes, bringing a whole range of metabolic problems within the scope of new and progressive exploration, restoring to work on the ductless glands the earlier spirit of hopeful enterprise, and sounding the advance into a new phase, in which endocrinology is still expanding with a speed which now puts a strain on the alertness and the scientific equipment of anyone who endeavours to keep pace with its headlong progress and its dazzling changes.

There have, of course, been a number of other important factors of this astonishing acceleration. One has been the concentration of studies on the pituitary body, in the medical and surgical clinics as well as in the experimental laboratory, and especially on the control over the functions of other ductless glands which is exercised by the hormones of its anterior lobe—a control which led the late Sir Walter Langdon-Brown, and others who have adopted his picturesque phrase, to describe the pituitary anterior lobe as "the conductor of the whole endocrine orchestra." Another has been the rapid elucidation of the once baffling interplay of endocrine activities involved in the sexual cycle. Yet another and most important factor has been the discovery of the true plan of the chemical structure of the sterols and their derivatives, providing the key to the chemical nature and relationships of the whole series of steroid hormones, including, as we shall see, those of the suprarenal cortex as well as those of the gonads.

We must make no further attempt, however, to range over the whole endocrine landscape. Any one section of it, if an endeavour were made to deal with it in full detail, could now provide the material for a whole course of lectures by somebody equipped so to present it. For several reasons I must bring our inquiry now to a narrower focus, and in the rest of this memorial lecture I shall ask you to look with me, still in rather hasty survey, and without any pretence at more than an occasional reference or attribution, at some of the recent developments of knowledge concerning the subject of Addison's own pioneer investigation, the suprarenal glands.

The Suprarenal Medulla

We must recall first that it was not till 1895 that it began to be understood that the suprarenal body consisted of two functionally different glandular organs bound together as cortex and medulla. In that year Oliver and Schäfer discovered the remarkable immediate actions of simple extracts from the gland when these were injected intravenously or, as in later experiments by others, were applied locally. Then the active principle responsible for these intense immediate effects was found to be localized entirely in the medulla of the gland; and just after the end of the nineteenth century it was isolated, as adrenaline or epinephrine, and eventually made by synthesis.

Meanwhile it had been discovered by Lewandowsky and by Langley, and then further demonstrated in fullest detail by Elliott, to whom the pure adrenaline was available, that there was a remarkable and unquestionably significant correspondence between the actions of adrenaline and those of the true sympathetic nerves. It is well known how Elliott's penetrating early suggestion (1904) that sympathetic-nerve impulses transmit their effects by liberating small charges of adrenaline at the endings of the nerve fibres was verified many years later by Loewi's brilliantly simple and convincing experiments from 1921 onwards. It thus became a component of a now familiar and wider scheme which pictures the effects of all efferent peripheral nerve impulses as evoked by the liberation of one or another chemical transmitter at the nerve endings. There remained, however, some grounds for uncertainty whether the adrenergic transmitter was always, or entirely, "adrenaline" itself, though the correspondence was so close that nobody doubted that there was a definite chemical relationship. The late W. B. Cannon took care to leave the question open by referring to the transmitter always as "sympathin"; and, apart from a further hypothesis which led him to complicate this terminology, Cannon was clearly right in emphasizing the departures from complete identity between the actions, on the one hand, of artificially applied adrenaline and those, on the other hand, of sympathetic-nerve impulses and of the actual transmitter escaping from the site of its liberation into the blood stream and carried therewith to act on a distant organ. I myself, as early as 1910, had emphasized the tendency of adrenaline to exaggerate the inhibitor in relation to the augmentor components, as seen in the corresponding actions of sympathetic nerves. In comment on Elliott's hypothesis, I had even then pointed out that the primary amine corresponding to adrenaline (*nor*-adrenaline, then known commercially as "arterrenol") reproduced the actions of sympathetic impulses with an even closer fidelity, in this respect, than adrenaline itself.

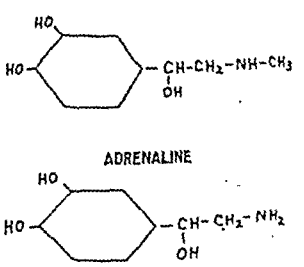

FIG. 1.

The evidence did not then seem to warrant a direct suggestion that *nor*-adrenaline might be the transmitting agent, or even a component thereof. Elliott's suggestion had at that time received but little notice, and *nor*-adrenaline was known then, and indeed till quite recently, only as a product of artificial synthesis.

But now, in the past year, the evidence has begun to flow in, arising simultaneously and independently in a number of different laboratories and in several different countries. Differential physiological reactions, contrived with much ingenuity and reinforced by fluorometric measurements, have made it possible to determine the proportional contributions of adrenaline and *nor*-adrenaline to the sympathomimetic activity of a fluid containing both. And by such methods it has been possible to prove that the sympathetic transmitter, as extracted from the sympathetic chain or from a purely adrenergic nerve, or found leaving the spleen in its venous blood during stimulation of its adrenergic nerve-supply, consists mainly of *nor*-adrenaline, with adrenaline itself as, at most, a minor component. Even the hormone secreted into the blood from the suprarenal medulla when the splanchnic nerve is stimulated, though it usually consists mostly of adrenaline during the early stages of such a stimulation, contains *nor*-adrenaline in increasing proportion as the process is repeated, and may even, after several periods, consist almost entirely of this primary amine.

These discoveries have interest for the pharmacologist and the chemist, and they remove certain puzzling discrepancies, but they make no fundamental difference to our conception of the endocrine function of the suprarenal medulla. We still regard it, following Cannon, as contributing immediate reinforcement to sympathetic-nerve actions on occasions of emergency, of sudden calls for

activity, or of emotional stress; and its hormone still figures also as the peripheral transmitter of the effects of adrenergic impulses. Only our conception of its chemistry is slightly changed. When first the actions of this medullary hormone were discovered it was natural to expect that a lack of it would be found to play at least an important part in the symptoms of Addison's disease, and evidence for such an effect of its exclusion was eagerly sought. As a result, however, we are left without any clear reason for attributing any conspicuous item of the Addisonian syndrome to simple lack of the endocrine function of the medulla. It is remarkably difficult, in fact, to detect any significant result from the removal of one suprarenal gland and extirpation of the medulla from the other. Even when Cannon removed, in addition, the whole system of the true sympathetic ganglia from cats, the animals remained healthy and exhibited only an unusual placidity. The fact that a melanin pigment is formed by oxidation of adrenaline or of its primary homologue might well suggest a connexion between a medullary defect and the bronzed skin of Addison's disease. Even in that case, however, there is no direct experimental evidence. Extirpation of the medulla does not cause any comparable pigmentation, though the possibility still remains open that a disorder, rather than a suppression, of the medullary metabolism normally producing the adrenalines may be responsible for the appearance of Addison's pigment.

What is now abundantly clear is that the main features of Addison's disease—the increasing debility and languor, the muscular weakness, the low arterial pressure, the decrease in blood volume, the disturbance of the normal balance of inorganic salts between body fluids and tissues, the liability to attacks of hypoglycaemia, and the general lack of the normal resistance to infection, poisoning, temperature changes, or any kind of harmful influence, this complex of symptoms leading to the inevitably fatal termination of untreated Addison's disease—are due entirely to the lack of the hormones formed by the cortex. It becomes ever clearer, indeed, that when Addison described his "melasma suprarenale" he was dealing with the collapse of a main arch of the functional structure by which a large proportion of the functions and reactions concerned in the maintenance of a healthy vitality are kept under endocrine control and regulation, and that the keystone of that arch was to be found in the hormones of the suprarenal cortex.

Cortical Hormones

After long discouragement and frustration, as an important item of the new and accelerating advance which set in after insulin was discovered, Swingle and Pfiffner in 1931 succeeded at length in preparing a stable and approximately purified extract of the cortical hormones by systematic injection of which life could be maintained in an animal deprived of its suprarenal glands. It was not long before, from several laboratories in different countries, crystalline fractions began to be obtained from cortical extracts, and a little later again the chemical nature of these began to be clarified. A few years earlier the chemical identification of pure hormones from the suprarenal cortex would have seemed an almost fantastic aspiration. Its achievement was greatly facilitated by the recognition, then recent, of the widely varied physiological significance of substances built by the attachment of different substituent groups and side-chains to a common hydrocarbon skeleton—the so-called cyclo-penteno-phenanthrene nucleus, forming the central structural feature of the sterols, the bile-acids, certain remedial glucosides, the steroid vitamin D, the steroid sex hormones, and, now, the steroid hormones of the suprarenal cortex. Many investigators have contributed to the amazingly rapid advance of knowledge of these substances, and mention can be made only of work by Kendall, and his co-workers of the research laboratories of the Mayo Clinic, in isolating several of these hormones from animal suprarenals, and of that of Reichstein, and his co-workers of Basle University, in producing members of the series artificially by synthesis.

At least six such active cortical steroids are known in pure crystalline form, and there is a highly active amorphous residue, probably containing a number of others. The evidence available concerning the different activities of those already isolated would by itself provide material for a course of lectures by an expert. In broadest terms, the hormones already recognized fall into certain main groups. The members of one such group are oxygenated at the carbon atom numbered 11 on the structural formula, while those of another group differ from the former only in having no oxygen in this position. Corticosterone (Fig. 2, I) is a representative member of the former group,

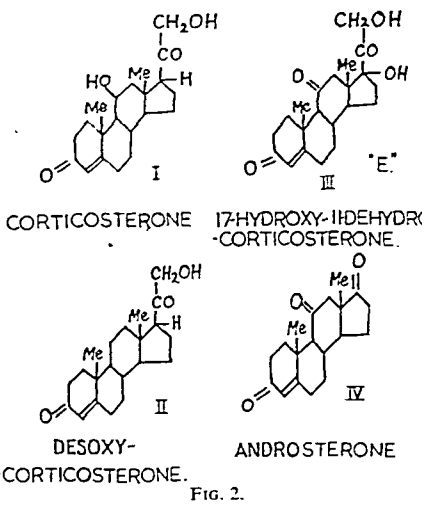

FIG. 2.

the actions of which are particularly concerned with carbohydrate metabolism. When given in excess they cause breakdown of cellular proteins, rise of blood sugar amounting to a temporary diabetes, with resistance to insulin, greatly increased excretion of uric acid, and a steep decline in the number of eosinophil leucocytes in the circulating blood. As a group, they may be regarded as the carbohydrate-controlling cortical hormones. A type of the other group is desoxycorticosterone (Fig. 2, II), and the characteristic action of these is to maintain the balance of inorganic salts in the body, with preponderance of sodium and chloride in the fluids and of potassium and phosphates in the cells. Lack of these hormones, which may be referred to as the salt-controlling group, causes loss through the urine of sodium and chlorides from the blood and body fluids and appearance in these of excess of potassium; administration of these hormones in excess causes over-retention of sodium and chlorides and water-logging of the tissues. Both these types of endocrine control are deficient in Addison's disease, and both must be replaced to preserve life, though lack of salt-controlling hormones can to some extent, and for a time, be made good by an added intake of sodium chloride. And there is another group, derivable from the 11-oxygenated series by replacement of the side-chain on the 17-carbon atom by oxygen: and the members of this group, of which

androsterone is a type (Fig. 2, IV), closely related to testosterone, the hormone of the testis, have indeed a sex-hormonal virilizing action.

Conclusion

The outlines are beginning to appear of the most complicated pattern of the complementary actions of these hormones in relation to one another; of their balanced actions against those of other hormones—for example, of some of them against the actions of insulin; and of the control of their formation and output by the so-called adrenocorticotropic hormone of the pituitary anterior lobe and apparently to some extent by the suprarenal medullary hormone adrenaline. I myself observed, as early as 1921, that a cat from which the suprarenals had been removed showed a greatly exaggerated sensitiveness to histamine, even before overt general signs of deprivation appeared. And, in more general terms, the part played by the cortical hormones in the whole scheme of the endocrine control of the body's functions and reactions, and especially, as Selye, of Montreal, has emphasized, in its adaptative reactions to almost all kinds of injury or stress, is undoubtedly one of central importance.

In further and most suggestive illustration of this function, in the case of at least one of the corticosteroids comes the recent news of therapeutic trials, at the Mayo Clinic and elsewhere, giving promise of a protective and curative effect of another member of the carbohydrate-controlling group, the 17-hydroxy-11-dehydrocorticosterone (Kendall's "Substance E," Fig. 2, III), against defective or perverted adaptative reactions responsible for rheumatoid arthritis. We shall wait eagerly for further evidence of advance in this new and surprising direction. And meanwhile I think you will agree that, if the anterior pituitary lobe occupies the conductor's rostrum in the endocrine orchestra, we must at least assign the leading violinist's desk to the suprarenal cortex. And surely no artificial monument to the memory of Thomas Addison could be so imposing as this great and now so rapidly growing tree of health-giving and life-saving knowledge, sprung from the seed which Addison dropped as he worked in this hospital with such patient devotion and with a clinical vision unsurpassed in its clarity and alertness.

The Report of the Food Investigation Board for the year 1939 has now been issued by His Majesty's Stationery Office, price 2s. 6d. Before publication could be effected when the report was originally prepared the type was destroyed by enemy action, and the document could not be issued until the present time because of restrictions on printing and paper. Some of the work described in the original paper has now been completed, and accounts have been published in various journals, to which references are given. Among the experiments described are tests on the control of microbial spoilage in meat by ultra-violet irradiation. Some retardation of bacterial growth was obtained, but the effect was not great. The storage of eggs was investigated, and experiments were carried out on freezing and storage of sprats before canning. Work was undertaken on the effect of acetylene and ethylene on the ripening of "Kelsey" South African plums. Treatment with either gas for three days accelerated ripening and improved the quality of the fruit, while untreated samples kept in air ripened slowly. Continued exposure to acetylene until the fruit ripened, however, made it too sweet. Research on blemishes on the rind of grapefruit stored at low temperatures, known as "low temperature spot," showed that wrapping in moisture-proof material instead of tissue-paper enabled lower temperature storage to be used, or the fruit to be stored longer. Other work included investigations of various methods of freezing strawberries, raspberries, and peas.

SOME PRINCIPLES UNDERLYING DETERMINATION OF SEX HORMONES*

BY

H. de WATTEVILLE, M.D.
Professor of Gynaecology and Obstetrics

S. SALINGER, M.D.
Assistant Biologist

AND

R. BORTH, Ph.D.
Assistant Chemist

Clinique Universitaire de Gynécologie et d'Obstétrique, Geneva

During the last two decades our knowledge of biological processes has been rapidly extending. Studies on sex hormones have had an outstanding influence on this advance. Research work and clinical experience have shown that specific principles formed in the pituitary, gonads, and adrenals profoundly affect the structure and function of the whole body. Therefore sex hormones, now available in highly purified preparations, have been introduced in many cases of gonadal and extragenital disorders either as substitution or as stimulation therapy. This use of hormones has enormously increased. However, it must always be remembered that no benefit can be expected from their promiscuous use. A critical attitude should be maintained in the management of endocrine disorders.

These disorders demand some understanding of sexual functions under various physiological and pathological conditions and a thorough knowledge of the hormone-producing organs and those involved in hormone metabolism. In cases of possible hormonal deficiency diagnosis and treatment are based both on the clinical picture and on the histological, biological, and chemical findings.

Any hormone determination is of value only in the light of a preceding clinical examination. Typical changes in weight, temperature, fatigue, appetite, growth and distribution of hair, and vascular, nervous, and other physical manifestations sometimes suggest the kind of sex-hormone imbalance present. The sexual sphere, as the most sensitive to hormonal influence, is the one most readily involved. Undisturbed sexual function may already exclude important hormonal disorders. Administration of sex-hormone preparations in such cases may be unwise and even harmful.

Further information on hormonal activity is obtained from histological and cytological examinations. In women, endometrial biopsy and vaginal smears reveal the uterine and vaginal response to ovarian stimulation. They are the simplest means of determining ovarian function. They show whether an ovarian deficiency exists and whether the disturbance involves suppression in the follicular or luteal phase, or both. They are used not only as diagnostic aids but also as a control to the efficacy of treatment. These clinical findings, however, vary with the responsiveness of the organ involved and are predominantly qualitative in character. They have to be completed by quantitative studies of sex hormones, data of which are provided by biological and chemical methods indicating hormone levels in blood and urine. These give evidence not only of the kind but of the amount of hormone produced. These determinations represent one of the most important diagnostic

*From a lecture delivered by Professor de Watteville to the Faculty of Ophthalmologists of London, at the Maternité of Geneva, on May 11, 1948.

aids and should be a part of the general clinical routine work.

Because of the importance of these biological and chemical findings, some principles underlying hormone determination are here discussed (see Tables I and II).

TABLE I.—*Substances to be Determined in Endocrine Disturbances of the Genital System*

Substances	Sources	Principal Target Organs	Material	Method of Determination
Gonadotropins	Pituitary Placenta	Ovary: follicle, corpus luteum Testes: interstitial cells	Urine Blood	Biological test
Oestrogens	Ovary (follicle) Placenta	Uterus: endometrium, myometrium	Blood	Biological test
	Adrenal cortex (neoplastic)	Vagina Mamma	Urine	Biological test Colorimetry, fluorimetry
Progesterone	Ovary (corpus luteum) Placenta	Uterus: endometrium, myometrium Mamma	Blood	Biological test
Pregnanediol	Progesterone (and corticosteroid) metabolite		Urine	Gravimetric, titration, colorimetry
Androgens	Testes: interstitial cells Adrenal cortex	Spermatogenic cells Prostate Seminal vesicles Penis	Urine (Blood)	Biological test
Corticosteroids	Adrenal cortex	Metabolism	Urine	Biological test, colorimetry
17-Ketosteroids, proportion α/β	Metabolites derived from adrenal and testicular steroids		Urine (Blood)	Colorimetry, polarography

TABLE II.—*Hormone Levels in Some Diseases*

Increased	Decreased or Zero
Gonadotropins	
Hydatid mole Chorionepithelioma Testicular teratoma Natural and artificial	Hypopituitary amenorrhoea Anovulatory failure of pituitary origin Chromophobic adenoma Craniopharyngioma Fröhlich's syndrome (adiposogenitalism) Simmonds's disease Laurence–Moon–Biedl syndrome Dercum's disease Diabetes insipidus Pituitary dwarfism
Oestrogens	
Hyperovarianism due to granulosa or theca-cell tumours Follicular hyperplasia Persistent follicular activity Feminizing adrenal tumour	Castration Menopausal ovarian involution Hypo-ovarianism (amenorrhoea, oligomenorrhoea, extragenital symptoms)
Pregnanediol	
Normal pregnancy Persistent corpus luteum Theca-cell tumour Certain adrenal tumours	Missed abortion Threatening abortion Anovulatory cycle Luteal deficiency
17-Ketosteroids	
Adrenal tumour	Addison's disease Chromophobic adenoma Simmonds's disease Myotonia dystrophica Pituitary dwarfism

Hormones affect what we may call the target organs by way of the blood. Determination of hormone levels depends upon the presence of hormones or their metabolites in blood and urine. In the *blood* they are as a rule present in *low concentration*. This represents a practical difficulty, as large quantities are required to obtain measurable values. This inconvenience is easily avoided, as *urine* hormone levels are *higher* and parallel those in blood. Although on the whole the amounts excreted do not exceed 5 to 20% of that present in the body, these are fairly well reflected by the excretion values. This fact has been proved from simultaneous blood and urine controls after the administration of hormone preparations.

Actually most hormone determinations are made with urine. No preserving chemicals have to be added to urine samples when they are examined within 24 to 48 hours after collecting. As the hormone concentrations vary with the quantity of urine eliminated, excretion values should be reported not in milligrams or units per litre but in milligrams or units per 24 hours. *Exactness in the collecting of urine is therefore necessary.* Whether a given specimen represents the complete 24-hour collection or not may be determined approximately by the amount of creatinine it contains, this substance being eliminated in most cases at a fairly constant daily rate (Smith, 1942). From the excretion values thus obtained deductions regarding hormonal activity in the body are justified provided that kidney and liver functions are normal.

Hormone output, however, has no constant normal value. It varies greatly, according to age, pregnancy, or the menstrual cycle, so that these physiological variations must be borne in mind when interpreting results. Furthermore, the determination of hormone levels should be carried out only at a suitable time (see Table III). Ignorance of these facts may commit laboratory workers to expensive and time-consuming examinations without providing any useful information.

TABLE III.—*Schedule for Sex-hormone Determinations in Urine*

In Men

Gonadotropins Androgens 17-Ketosteroids Oestrogens (in cases of feminizing tumour)	Twice within a few days

In Women

(*a*) During the menstrual cycle:

	Urine, to be Collected on the Following Days of the Cycle			
	10th–11th	15th–16th	20th–21st	25th–26th
Gonadotropins ..	(x)	X	x	(x)
Oestrogens	x	X	x	(x)
Pregnanediol ..	—	(x)	X	x
17-Ketosteroids	Twice during the cycle			

X = Urine samples of high diagnostic value.
x = " " " medium " "
(x) = " " " little " "

(*b*) In pregnancy:
Gonadotropins .. .. From the 35th day of amenorrhoea onwards
Pregnanediol .. .. .. " " 29th " " " "

(*c*) Pre-puberty—Menopause—Amenorrhoea:
Gonadotropins, Oestrogens .. .. Three times, once every 7–10 days
17-Ketosteroids, Androgens (in cases of virilizing tumour) Twice within a few days

Methods

Determination of sex hormones is carried out by chemical methods or by biological tests on the animal. Chemical methods are cheaper and simpler than biological tests because no stock of test animals has to be kept. Standard techniques, giving similar or even equal results in different laboratories, can be established more readily for chemical methods than for biological tests. In most instances chemical procedures take less time than biological reactions. On the other hand, chemical procedures should not be introduced without the assistance of a trained chemist.

The main difference between the two methods lies in the fact that bio-assays measure the biological activity of an extract which may contain not only the hormone but also its active or inactive metabolites; it is evident that the latter are no less important than the hormone itself, but they cannot be detected by bio-assay methods. On the other hand, chemical methods, while presumably a test for hormonal activity, do not measure anything but the amount of chemical substances which have in common certain chemical reactions or physical properties. Therefore the development of chemical methods of hormone determination depends upon the proof (*a*) that certain chemical structures with specific properties are typical for a hormone

and/or its metabolites, and (*b*) that no other substances present in the extract under consideration show the same properties or interfere with the reaction employed.

Unless these two facts have been established by biochemical research no chemical determinations are possible. That is why gonadotropins, for instance, as protein compounds of unknown chemical constitution, are tested exclusively by biological methods. (Compare, however, the work of Mello, 1943.) Bio-assay measurements are comparative and require the use of a reference standard, because differences in strain, living conditions, and age of test animals (mostly mice, rats, and rabbits) sometimes lead to divergent results. Therefore values obtained from biological tests by different research workers are comparable only if related to the international unit of a standard preparation.

Some clinicians prefer biological methods, arguing that biologically active principles can be measured only by the response of a living organism. But actually the respective proportions of active principles and the corresponding chemical fractions in human urine are fairly well known. Chemical and biological standard methods are therefore regarded as equally reliable and informative.

Gonadotropins

Aschheim and Zondek, and independently Smith, in 1926–7 observed that immature mice respond to implantations of pituitary or injections of human pregnancy urine with precocious ripening of their ovaries. This reaction is the effect of the gonadotropic hormones. *These are not sex-specific,* as they stimulate male as well as female gonads.

In the pituitary two fractions of gonadotropins are produced: the follicle-stimulating hormone stimulates primordial follicles of the ovary to develop into mature follicles, which in turn produce oestrogens; the luteinizing hormone transforms the ruptured follicles into corpora lutea, which in turn will produce progesterone.

Gonadotropins also have a stimulating effect on the size and functional activity of the testis.

A source of gonadotropins other than the pituitary is the placenta, which is the chief producer of the luteinizing factor. Tumours derived from chorionic tissues likewise produce gonadotropins, the amounts far exceeding those already high during pregnancy.

Generally, routine biological tests determine both fractions together. Separation of follicle-stimulating hormone and luteinizing hormone is done only in biological research work and is not used for clinical examinations.

Determinations of high gonadotropin levels in body fluids are of practical importance for the early diagnosis of pregnancy. A drop to subnormal values indicates foetal death. Excessive rise in gonadotropin titres as proved by a positive Aschheim–Zondek reaction with highly diluted samples of urine indicates pathological growth of hormone-producing chorionic tissues, such as hydatid mole, chorion-epithelioma, and some kinds of teratoma containing chorionic cells.

In conditions other than pregnancy only small amounts of gonadotropins are present. Therefore they must be concentrated before they can be measured by the biological tests available. During the menstrual cycle gonadotropin excretion rises and falls, with a peak about the time of ovulation. Several determinations have therefore to be made, the most important one being in mid-cycle.

In castrates of both sexes, in old men, in women at the menopause, and in conditions due to primary ovarian failure a rise of gonadotropin levels has been demonstrated. This fact is said to be at least partly responsible for climacteric troubles.

The pituitary gland influences the whole endocrine system. Therefore control of gonadotropins is of interest in all cases in which endocrine dysfunction is suspected. High levels of gonadotropins are to be expected in pituitary basophilic hyperplasia or adenoma and in organic diseases of the hypothalamus. On the contrary, low values are found when the basophilic cells of the pituitary are destroyed by tumour growth—for example, in cases of chromophobic adenoma, eosinophilic adenoma, and craniopharyngioma or some other intracranial tumours—and in all cases of symptomatic or idiopathic pituitary atrophy, such as Simmonds's disease, Dercum's disease, and the syndromes of Fröhlich and Laurence-Moon-Biedl.

Oestrogens

The three naturally occurring oestrogens considered here are oestradiol, oestrone, and oestriol, the first being the most potent, the last-named the least potent. They are formed not only in the ovary and in the placenta but, in much smaller amounts, also in the adrenals and in the testes. Possibly only oestradiol is actually elaborated by the glands, the two other oestrogens being its metabolites. All three are excreted in urine, to a small extent as such, but mainly in conjugated form as sulphate or glucuronide. The only *inactive* metabolites known are the oestranediols, which, however, have no clinical importance.

The oestrogens stimulate proliferation of the myometrium, endometrium, and vagina, and furthermore they develop the mammary gland and other secondary sex characters.

The most widely employed biological test (Emmens, 1939; Pedersen-Bjergaard, 1939) is based on the ability *of oestrogenic hormones to induce cornification of the* vaginal epithelium in spayed mice and rats. Positive reaction is demonstrated by the presence of cornified cells in the vaginal smear. For the determination of low oestrogen concentrations the histological demonstration of vaginal mucification preceding cornification has been used (Fluhmann, 1930). These biological tests necessitate a previous chemical preparation of urine involving liberation of the active principles by hydrolysis of the inactive conjugated oestrogens, followed by extraction and concentration.

Numerous chemical procedures have been described in the literature using colour reactions of the oestrogenic phenols for their colorimetric determination. Unfortunately, they can replace bio-assay only in conditions such as pregnancy, when high levels are present. To the clinician it is much more important to determine the small amounts excreted during the menstrual cycle. This seems to be achieved by a fluorometric method (Jailer, 1947–8) the principle of which has long been in use in veterinary medicine as a qualitative pregnancy test in mares (Cuboni, 1934).

Chemical determination as well as bio-assays may be done after separating the three oestrogens in order to determine their respective amounts. This chemical separation (Pincus, 1945; Friedgood *et al.*, 1948) complicates the technique considerably, but nevertheless it may be worth while because of the additional information on oestrogen metabolism which can be obtained.

The rate of oestrogen excretion in urine varies during the stages of the menstrual cycle. The highest values are encountered at the end of the follicular phase, and considerable amounts are still present during the luteal phase.

Before the onset of the menstrual flow a sharp drop occurs. Thus several determinations are necessary to adjudge the oestrogenic activity of the ovary. This determination of the rate of oestrogen excretion may be of importance in the detection of slight pathological deviations of oestrogen levels, which may cause functional troubles even when no morphological changes or menstrual disorders are observed.

The same clinical symptoms may be produced by different oestrogen production, as, for example, in amenorrhoea, in which oestrogen values may be low or high, cyclic or acyclic.

As practically no oestrogens are detectable in menopausal women, positive tests suggest hormone-producing tumours of the ovary or of the adrenals. Also, in the male, tumours of the adrenals, and especially adrenal carcinoma, may produce considerable amounts of oestrogens.

Progesterone and Pregnanediol

Gonadotropins stimulate not only oestrogen but also progesterone production in the ovary. The latter hormone is elaborated in the corpus luteum and, from the third or fourth month of pregnancy onwards, in the placenta. Its principal actions are: (1) the secretory transformation of the uterine mucosa, and (2) the muscular relaxation of the whole uterus. These progestational changes allow of the implantation of the fertilized ovum and make possible the undisturbed growth of the embryo.

The biological assay of progesterone makes use of the effect of this hormone on the endometrium. The test animal is the immature (Clauberg, 1930) or castrated (Corner and Allen, 1929) rabbit, which must have received preparatory treatment with oestrogen in order to induce the proliferative phase of its endometrium. The test is positive if in the histological examinations signs of secretory transformation are observed. By intrauterine administration of the material to be tested (de Allende, 1940; Hooker and Forbes, 1947) even the small amounts of progesterone present in the blood of normal women during the second half of the menstrual cycle can be detected. The test, however, is not rigidly specific for progesterone, because two other hormones—namely, testosterone (from the testis) and desoxycorticosterone (from the adrenal cortex)—are also able to induce the transformation of the proliferated uterine mucosa into its secretory phase. Of course, the respective activities are not the same. The doses required, as compared with progesterone, are six times greater for desoxycorticosterone and twenty times greater for testosterone.

The biological assay of progesterone gives positive results only with certain tissue extracts and with blood, but in urine practically no progesterone can be detected. This is explained by the rapid inactivation of this hormone within the body, leading partly to the formation of pregnanediol. This progesterone metabolite is eliminated in urine in conjugated form as sodium pregnanediol glucuronidate. Its chemical constitution differs only slightly from that of the parent compound, progesterone, but nevertheless it has no biological activity at all and can be determined only by chemical methods.

We use a method of our own (de Watteville *et al.*, 1948) which is relatively simple, reliable, and rapid. It is based on hydrolysis of the glucuronide and simultaneous extraction of the freed pregnanediol, followed finally by chromatographic isolation of the pure compound by means of an aluminium oxide column. The crystalline pregnanediol is weighed, and its purity can be controlled by determination of the melting-point.

Clinical experience has shown that, broadly, urinary pregnanediol levels parallel progesterone action observed in the organism. We are entitled, therefore, to use the pregnanediol level in urine as a reliable indicator of progesterone production by the corpus luteum or the placenta. The minimal amount of pregnanediol derived from normal adrenal steroids is too small to interfere with determinations during the menstrual cycle or in pregnancy. It acquires, however, some value as a diagnostic aid when considerably increased by certain adrenal tumours or adrenal hyperplasia. Still, the chief importance of pregnanediol determination lies in gynaecological and obstetrical diagnosis.

Together with the assay of gonadotropins, pregnanediol is employed as a test for normal or disturbed pregnancy. In threatened abortion normal or decreased pregnanediol levels are most informative regarding whether the further evolution will be good or bad. In cases of threatened or doubtful missed abortion the decision whether to interrupt pregnancy or not can almost exclusively be based on pregnanediol values.

Pregnanediol determinations are also very useful during the second half of the menstrual cycle. Normal values between the sixteenth and twenty-sixth days of the cycle are conclusive evidence that a normal corpus luteum is present. On the other hand, zero values are found only in anovulatory cycles when follicle rupture does not occur and no corpora lutea are formed. Finally, if pregnanediol values are too low, or if the period of excretion is too short, then progestational deficiency is strongly suggested.

It is well known that the ovary is not autonomous. Corpus luteum function, as well as follicle ripening, depends upon pituitary gonadotropins, and its disorders may be caused either by a primary ovarian deficiency or by disturbances of the pituitary. The latter, however, may be responsible for quite a lot of other more general disorders—for instance, post-partum obesity, which shows luteal deficiency of pituitary origin and can be successfully treated with pituitary luteinizing hormone. The meaning of all this is that normal pregnanediol values, if considered together with the clinical picture, enable us to exclude either ovarian failure or disorders of the gonadotropic function of the pituitary.

Androgens and 17-Ketosteroids

Testosterone is the characteristic endogenous hormone of the testicle. In the human body it is converted partly to androsterone and other 17-ketosteroids of less or no biological activity. These conversion products are excreted by the kidneys, but no testosterone is found in urine. Androgenic activity as well as 17-ketosteroids have been demonstrated in the urine of children and adults of both sexes. This is explained by the fact that androgens and 17-ketosteroids are not only of gonadal but also of adrenal origin. The normal output of 17-ketosteroids varies with age and sex: an extensive study of this subject (including standard curves) has been published by Hamburger (1948). In women, adrenals are by far the most prolific source of androgenic substances and 17-ketosteroids, the concentration of these being almost the same in normal and ovariectomized women, but less than in urine of normal men. Nevertheless, the ovaries also seem to be capable of androgen formation, as is strongly suggested by the fact that virilism may be caused by arrhenoblastoma. In men, both adrenals and testes are concerned with androgen and 17-ketosteroid elaboration: it is supposed that the testes account for 20 to 40% of the urinary 17-ketosteroids.

Determination values, therefore, are not a conclusive index of spermatogenic function, but in case of deficiency they may provide a clue to the incretory status of the testes and indicate a deficiency of the testicular hormone. Eunuchoids, for instance, excrete appreciably less androgens than normal men. In cases with destructive processes of the adrenals, such as Addison's disease, the values found are also low.

In some castrated and menopausal women and in those with arrhenoblastoma 17-ketosteroids tend to be increased. Urines from cases with adrenal hyperplasia or tumour yield enormous quantities of certain 17-ketosteroids. Therefore a rise in 17-ketosteroid output may be regarded as an aid in the differential diagnosis between Cushing's disease due to adrenal cortical tumour and that of pituitary origin where the level is apparently within normal limits.

The biological assay (Gallagher *et al.*, 1937) is based on the ability of androgenic material to promote comb-growth in the capon. To replace the biological test Zimmermann's (1935, 1946) colorimetric *m*-dinitrobenzene reaction, as modified by Callow *et al.* (1938) and many other workers, is now widely used for the determination of urinary non-phenolic 17-ketosteroids. To increase the specificity of this method it is strongly recommended to eliminate unspecific chromogens from the extract, using chromatography (Talbot *et al.*, 1941), charcoal (Consolazio and Talbott, 1940), or Girard's reagent T (Talbot *et al.*, 1940). Even then the 17-ketosteroid values obtained are too high if the 20-ketosteroids of pregnancy urine are present to contribute to the colour intensity. Pincus's (1943) antimony trichloride reagent seems to be more specific, but it does not react with dehydro-isoandrosterone, an important 17-ketosteroid in the β-fraction. The neutral steroid fraction of human urines can be separated into an α- and a β-fraction of ketosteroids (Pincus, 1945). The determination of these two fractions may aid in the differential diagnosis between adrenal cortical hyperplasia and adrenal carcinoma, the β-fraction being markedly increased in the latter.

Much useful information could be gained from fractionating the extracts still further in order to trace individual steroids instead of groups. Unfortunately, the chemical procedure involved (Dingemanse *et al.*, 1946) is too laborious to permit its use in daily clinical routine work.

The value of the determination of androgens and 17-ketosteroids in the diagnosis of gonadal and adrenal disorders is limited, because of great individual variations in both normal and abnormal subjects. Repeated determinations in the same subject, however, may yield some information about the evolution of an endocrine disease and about the therapeutic success. With regard to single determinations, significance can be attributed only to the very high figures occurring in cases of adrenal tumour.

Conclusions

Clinical endocrinology, although complicated, is of increasing importance. In order to stress this importance we may give some final conclusions: (1) Hormone determinations are of value only when considered simultaneously with, and in close relation to, the clinical picture of a case. (2) The usefulness of routine hormone determinations is threefold—theoretical, diagnostic, and therapeutic. (3) Their *theoretical* importance lies in basic research work on hormone metabolism, when we are trying to learn everything about the fate of hormone substances within the body, how they are produced, transformed in the target organ, inactivated, and excreted. (4) In *diagnosis* they provide valuable information on glandular functions, indicating whether these are normal, increased, or deficient. (5) In *therapy*, at last, they help us to judge the effect of hormone treatment on internal secretion—whether we have succeeded in stimulating, substituting, or regulating the functions we meant to influence.

Hormone research and its clinical applications are in full progress, but much work has yet to be done. We can be sure that the result of future research will extend still further the assistance which the physician already receives from the laboratory.

Readers not familiar with the steroid nomenclature mentioned in this paper are referred to the instructive survey by Mason (1948).

We are indebted to Harris and Thimann (1943–7), Burrows (1945), Hamblen (1945), and Pincus (1947–8), whose books and reviews may profitably be consulted for further and more detailed information.

The Ministry of National Insurance reports that seven million new claims to sickness benefit have been made in the first year of the scheme that started on July 5, 1948—an average of 140,000 a week, about one half of which included claims for dependants. New claims rose to a peak of 220,000 during the week ending Feb. 22; the present rate is about 100,000 a week. About three-quarters of a million claims have been made for Industrial Injuries benefits of all kinds during the first year. Some 16,000 claims are made each week for injury benefit, and claims to disablement benefit are being received at the rate of nearly 6,000 a month. Claimants are being examined by 103 medical boarding centres to assess the degree of disablement, and 13 medical appeal tribunals hear appeals against assessments. Just under 200 claims a month have been received for the death benefit paid to the widow or to certain other dependants of a man who has died as a result of an industrial accident or disease.

POLIOMYELITIS AND THE SOCIAL ENVIRONMENT

BY

A. BRADFORD HILL, D.Sc., Ph.D.
Professor of Medical Statistics, London School of Hygiene and Tropical Medicine

AND

W. J. MARTIN, D.Sc., Ph.D.
Of the Statistical Research Unit of the Medical Research Council

One of the most striking but unexplained characteristics of poliomyelitis, to which many workers have drawn attention, is its relatively greater incidence and epidemicity in countries with high standards of living and good sanitation. In contrast it has "remained endemic and sporadic in countries where living conditions are poor, sanitary facilities minimal or non-existent, and infant mortality high" (Horstmann, 1948). Correspondingly, while water supplies and means of excreta disposal have been improved, while social conditions and nutrition have been steadily advancing, the disease has risen in many countries from sporadic or only small-scale appearances to epidemics on a wide scale. There seems no doubt whatever that this change is predominantly real, though its actual magnitude may well be exaggerated by the increasing attention paid during the last 50 years to the abortive and non-paralytic cases.

Somewhat similarly, the early literature on poliomyelitis contains constant references to the victims of the disease as healthy and strong children—indeed, Heine himself made such comment over a hundred years ago. This observation—if in fact the disease does fall with significantly greater frequency upon such children—might be explicable on the grounds that the strong and healthy by taking more muscular activity run a greater risk of bringing themselves into the paralytic class and thereby of being more often observed (Russell, 1947).

It has also been stated, and not infrequently, that the cases in a localized outbreak have been unduly concentrated in the better and more sanitary parts of the area. Thus, for example, Gilloran (1949) quotes the report of the medical officer of health for Beaminster rural district (Dorset) on a small outbreak in 1914: "The cases nearly all occurred . . . in the least-crowded and most sanitary part of the town on the main street." Going further afield, an inverse relationship between population density and attack rate was reported in the Mauritius outbreak of 1945 (McFarlan *et al.*). There is no dearth of such comments in the literature.

More recently, and arising out of the unprecedented epidemic that took place in Great Britain in 1947, it has been suggested that within a country exposed to a widely spread outbreak the incidence is likely to fall more heavily upon the communities that enjoy the most favourable environment and the best social conditions. Thus in a discussion of the poliomyelitis experience of the borough of Luton in 1947 it was said that "the birth rate was 21.3, death rate 9.4, infantile mortality rate 36, stillbirth rate 21.3, and maternal mortality rate 0.8. The outbreak was therefore set in circumstances of good health and low infection—a characteristic of poliomyelitis which seems to favour populations in favourable conditions where public health services are above the average" (*Med. Off.*, 1948).

Such striking events, however, may easily meet the eye and lead to comment while more normal or more expected happenings naturally tend to go unobserved and unrecorded. A full statistical account of the distribution of cases in relation to social environment is needed, and this we have attempted for the epidemic of 1947.

The Statistical Data

Through the kindness of the Registrar-General we were provided with the number of corrected notifications of poliomyelitis (including polio-encephalitis) in each of the 125 great towns and the 148 smaller towns of England and Wales in the year 1947. From these we computed the poliomyelitis attack rate during the year in each town (necessarily the crude rate at all ages, since attacks by ages are not available).

In the absence of a census since 1931 we have no up-to-date measure, in these towns, of overcrowding or of social-class attributes to use as our index of environment. Such characteristics are, however, invariably correlated closely with the infant mortality rate and to some extent, but less closely, with the general death rate. These, it will be recalled, were used as evidence of the social setting of the epidemic in Luton. As an indirect index of the environment we have therefore used these rates as computed for each town in the two years previous to the epidemic, 1945 and 1946 (the mean rate for these years).

Results

Correlation of the recorded attack rate from poliomyelitis with the specified mortality rates gave the following results (coefficients of correlation):

	125 Great Towns	148 Smaller Towns
Attack rate of poliomyelitis and crude death rate	−0·10	+0·04
Attack rate of poliomyelitis and infant mortality rate	−0·04	−0·13

These coefficients are all technically insignificant and therefore reveal no association between the incidence of poliomyelitis and the total and infant death rates of the towns.

The infant mortality index covers, by definition, the whole of the first year of life. It is, however, well known that the social and economic environment is mainly correlated with the mortality of the latter parts of the first year of life and less closely associated with deaths in the neonatal period. We therefore computed the degree of association between the attack rates of poliomyelitis and the infant mortality experiences of the great towns in 1945, limited to the ages 1–12 months and 6–12 months. The coefficients of correlation were as follows:

	125 Great Towns
Attack rate of poliomyelitis and infant mortality at 1–12 months of age	+0·08
Attack rate of poliomyelitis and infant mortality at 6–12 months of age	−0·07

Once more the coefficients are very small and again they are technically insignificant.

Reverting, therefore, to the total infant mortality rate—i.e., over the whole of the first year of life—the distribution of the poliomyelitis incidence in the total 273 towns in relation to this social index may be shown as in the table on the next page.

As follows inevitably from the insignificant correlations shown above, there is at every level of infant mortality a very wide scatter in the level of epidemicity of poliomyelitis. Over infant mortality rates ranging from 30 to 60 per 1,000 there is clearly no material difference between the percentage distributions showing the frequency with which different attack rates of poliomyelitis were recorded. At the two extremes of infant mortality, under 30 and

acid formation and the actual site of caries development a plug of persistent protein intervenes which would doubtless buffer the acid and protect the deeper part of the groove from being damaged. These considerations suggest that it is highly unlikely that lactic acid formed in "plaques" is the cause of caries beginning at the bottom of the occlusal groove.

These contentions are supported by the following experimental findings. If a perfectly sound molar tooth is placed in a solution of 2% HCl the enamel is in time completely dissolved away, but the protein contents of the groove are left intact. Any lactic acid, therefore, which is formed in a "plaque" in the superficial part of the occlusal groove could not dissolve away the persistent protein content of the groove and thus could not reach the bottom of the groove, where caries actually first sets in. The conclusion is therefore that, whatever may be the role of lactic acid in caries formation in other sites, lactic acid formation cannot account for the development of caries at its commonest site—i.e., at the bottom of the occlusal groove.

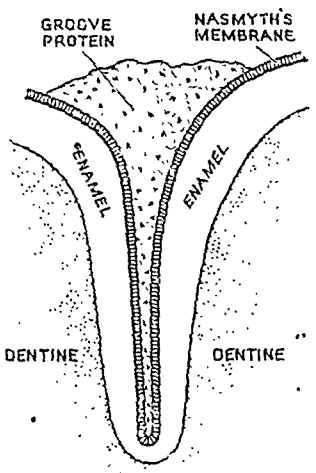

FIG. 2.—The occlusal groove in a newly erupted tooth.

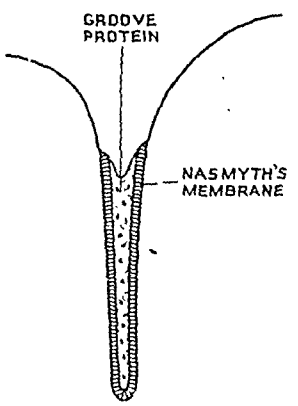

FIG. 3.—The occlusal groove in a tooth which has been in use in the mouth.

releases combined acid from the form in which it exists in mucoproteins. Such sulphatase-forming bacteria are present in the mouth as Gram-negative bacilli.

In the present work three sources of sulphatase have been employed—two strains of Gram-negative bacilli found in carious material, and *Aspergillus oryzae*. Material has been extracted from human dentine which when exposed to sulphatase releases sulphuric acid. The sulphatase has so far not attacked intact dentine or enamel protein; the extracted material on which it does act is a polysaccharide in which combined sulphuric acid is present. The dentine protein consists of a protein moiety collagen and the polysaccharide already referred to. Before the sulphatase can act on the tooth it would seem that initial hydrolysis of the protein to release the polysaccharide must take place; it is not known at present how this initial reaction occurs. The presence of a similar polysaccharide has been demonstrated in enamel protein, and there is some evidence that it is also present in groove protein. It is thought that the sulphatase of the Gram-negative mouth bacilli acts on

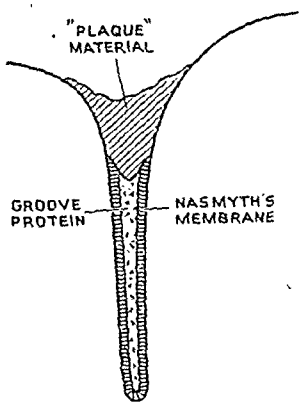

FIG. 4.—The situation of "plaque" material in relation to groove protein and Nasmyth's membrane.

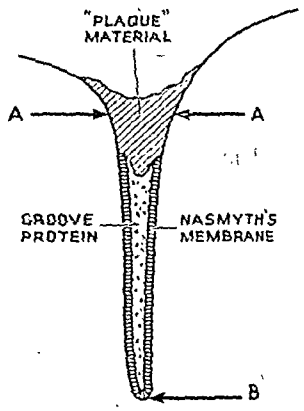

FIG. 5.—(As Fig. 4.) The arrows AA show where caries might be seen if it followed the breakdown of "plaque" material. Arrow B shows where caries in an occlusal groove is usually found.

2. Relation of Tooth Structure to Caries

The well-known work of Mellanby and Mellanby (1948) demonstrated conclusively that the structure of a tooth depends on the adequacy of the diet in respect of calcium, phosphorus, and vitamin D content. They found, further, that better-formed teeth are less liable to be affected by caries than less-well-formed teeth. The outstanding practical importance of these observations is obvious, but their work does not as yet explain the actual mechanism by which caries is produced in teeth of poor structure.

A Suggested New Chemical Theory of Caries

All previous theories stress the importance of the inorganic constituents of a tooth in relation to caries production. In the new theory to be outlined here it is suggested that the *organic* constituents of a tooth are of major importance. Excluding the cementum and pulp tissue, three proteins are found in teeth—namely, groove protein, enamel protein (Nasmyth's membrane and its prolongations into the enamel), and dentine protein. Dentine and enamel proteins have been examined in some detail, and both have been found to contain combined sulphuric acid. Enamel protein is a mucoprotein (Pincus, 1949). Neuberg and Hofmann (1931) demonstrated that many bacteria can form an enzyme, called sulphatase, which

the polysaccharide in these various tooth proteins, thus releasing sulphuric acid.

It is the initial freeing of combined sulphuric acid that forms the main feature of the present hypothesis. When the acid is freed by bacterial enzyme attack equilibrium is maintained at the expense of the calcium salts. At any given moment of the carious process the only free acid will be that which, having been released from one organic combination, has not yet formed a different combination with the calcium salts. The changes in the organic structures of the teeth are thus regarded as primary and those in the inorganic structures as secondary in the process of caries.

The release of sulphuric acid in enamel and in dentine may be expected to produce different effects on these two tissues as shown by experiments in which enamel and dentine were exposed to acid. Enamel attacked by acid becomes friable and is easily lost, while dentine attacked by acid may remain little changed on gross examination, apart from becoming softened. This difference in behaviour is accounted for by the fact that the inorganic material in enamel and in dentine may amount to 95% and 75% respectively. Thus the enamel exposed to acid will lose up to 95% of its constituents, while the dentine will lose only 75%, leaving an adequate organic framework to maintain its general arrangement.

It is important to note that in clinical caries a similar state of affairs is found—i.e., the enamel is friable and readily lost, while the dentine is softened. It follows from the hypothesis enunciated above that $CaSO_4$ should be present in carious material as a result of the interaction of the released sulphuric acid with calcium phosphate. In fact, $CaSO_4$ has been demonstrated in carious material, and it is absent from sound tooth structure.

Gram-negative sulphatase-producing bacilli would thus be the ultimate cause of caries. We do not yet know what are the conditions which determine the production and activity of the enzyme by these bacilli. Such conditions may play a large part in precipitating or preventing caries. This hypothesis argues that any organism in the mouth which can release sulphatase may be a factor in the production of caries. In other words, caries is not due to a specific bacillus but to specific enzymes, one of which has already been demonstrated, though obviously enzymes other than sulphatases are also involved in the complex process of initiation of caries.

The conditions at the bottom of an occlusal groove would seem to be favourable for the multiplication of the Gram-negative bacilli and the release and action of the sulphatase and other necessary enzymes. If the enamel were first attacked this would enable the organisms to penetrate into the dentine. Although the organisms might initially enter the dentine through a minute site of destruction in the enamel, once they had got into the dentine they could further damage the enamel from its deeper aspect.

The question still remains to be answered whether the hypothesis enunciated above can account for caries in situations other than the bottom of the occlusal groove. $CaSO_4$ has been demonstrated in carious material no matter what the site from which it has been obtained, provided enough material is available. In other words there is an *a priori* reason for supposing that sulphatase-forming bacteria may be concerned in caries production anywhere in a tooth.

Experimental Details

Organic Material Present in Enamel and Dentine.—Protein is found on the surface of newly erupted enamel (Nasmyth's membrane) and permeates the enamel in the form of threads, one such between each enamel prism and its neighbour (Fig. 6). The presence of organic material in enamel can easily be demonstrated. After a thin slice of enamel has been slowly attacked by a weak acid so that most of the inorganic matter passes into solution, microscopical examination shows fine strands of an acid-resistant nature which remain *in situ*, leaving a replica of the structure of the enamel, though this is now made up of organic material. Histological examination suggests that the organic material is a mucoprotein. In the present work sections of developing human enamel have been stained with thionin, when material resembling mucin was seen (Pincus, 1948c). Wislocki *et al.* (1948), using histochemical methods, found that the ground structure of the enamel organ resembled an "epithelial mucus," comparable in staining reactions to the acid mucopolysaccharides of some connective tissues. Chemical examination of the organic material has shown it to be a mucoprotein. Its chemical composition is: nitrogen 5.1%, sulphur 0.4%, hexosamine 11.2%; while the following qualitative tests are positive: Millon, xanthoproteic, Sakaguchi, ninhydrin, *p*-dimethylaminobenzaldehyde, naphthoresorcinol, carbazole (Dische, 1947).

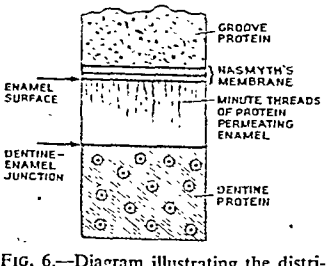

FIG. 6.—Diagram illustrating the distribution of tooth proteins.

Mucoproteins and Chondroitin Sulphuric Acid.—Few direct observations on the amount of protein present in enamel have been made. As a rule, determinations of nitrogen are carried out and the amount of protein calculated from these results. Since mucoproteins contain a lower percentage of nitrogen (10%) than do other proteins (15%), it will be clear that the actual amount of protein present in enamel may be 50% greater than has previously been supposed. To arrive at a result more directly, the protein must first be separated from the enamel, a matter of some difficulty. This point is emphasized to show that the amount of protein present in enamel is sufficient for the production of acid as demanded by the new theory, and may amount to 5% by volume. It is known that dentine contains collagen (Harrow, 1946), and I have demonstrated that dentine contains the polysaccharide chondroitin sulphuric acid, which may be separated from dentine by the use of a method similar to that employed to separate the polysaccharide from cartilage (Meyer and Smyth, 1937). The composition of chondroitin sulphuric acid separated from dentine is: nitrogen 1.7%, sulphur 4.6%, acetyl 8.1%, hexosamine 26.3%, hexuronic acid 28%.

Caries Bacteria

In earlier work (Pincus, 1948d) I have shown that, when mixed caries bacteria were inoculated into tubes containing cartilage (which is rich in chondroitin sulphuric acid) and incubated at 37° C., first Gram-positive forms resembling enterococci grew, while, later, Gram-negative bacilli resembling those of the *Proteus* group eventually outgrew all other forms. Both the Gram-positive and the Gram-negative forms were classified by their characteristics as shown in pure culture. Now, Gram-negative bacilli of the *Proteus* group are found in caries (Hine and Bibby, 1939); Neuberg and Hofmann (1931) have demonstrated in Gram-negative bacilli of the *Proteus* group the presence of an enzyme (sulphatase) that can liberate sulphuric acid from organic compounds in which it is present in combined form—e.g., mucoitin and chondroitin sulphuric acid. I have suggested above that such bacilli are present in the mouth and may play a part in caries by releasing sulphuric acid from the organic compounds in which it exists in the teeth. Evidence is presented elsewhere that bacterial enzymes can release free sulphuric acid quantitatively from both chondroitin and mucoitin sulphuric acid, which can be split off from enamel and dentine proteins.

It may be seen that caries of enamel and of dentine may be accounted for by the hypothesis set out above, for which there is some experimental support. The fact that a large mass of carious dentine is often found in a tooth despite the tiny size of the point of entry in the enamel is a clinical commonplace for which the present hypothesis offers a reasonable explanation. In the new theory, once suitable organisms gain access to the dentine bacterial growth and enzyme production may proceed, using as nutriment that available in the tooth itself. No nutritional factors other than these would then be needed.

Summary

Between the cusps of molar teeth lie grooves which, especially if narrow, are a common site of caries. These grooves in newly

erupted teeth contain two structures which differ in biochemical nature; one is a mucoprotein.

Enamel at eruption is covered with a layer of protein, and is permeated with protein throughout life. Enamel protein is a mucoprotein, which comprises a class of proteins containing mucoitin sulphuric acid.

Dentine contains chondroitin sulphuric acid.

Gram-negative bacilli found in caries can release an enzyme —sulphatase.

Sulphatase can release sulphuric acid from such combined forms as mucoitin sulphuric acid and chondroitin sulphuric acid, thus attacking the calcium salts of both enamel and dentine and causing caries.

To my colleagues at the hospital and to the Medical Research Council, which has provided financial facilities, I wish to express my indebtedness.

A CASE OF PSITTACOSIS TREATED WITH PENICILLIN

BY

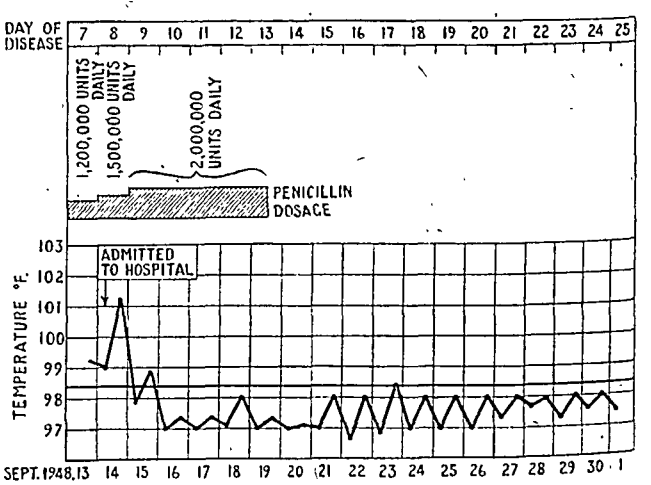
J. R. TASKER, M.B., M.R.C.P.

Medical First Assistant, London Hospital

The purpose of this note is to report the case of a patient infected with psittacosis who responded to treatment with penicillin.

Case History

A medical research worker aged 43 was admitted to hospital on Sept. 14, 1948. His work during the previous three months had involved the handling of material obtained from mice infected with psittacosis virus.



Two weeks before admission he had developed severe coryza. Six days later (eight days before admission) he suffered the sudden onset of marked malaise, shivering, and high fever (temperature 103° F.—39.4° C.) associated with severe headache and vomiting. He went to bed, and the symptoms persisted unchanged for 48 hours. Then they suddenly abated, and for 12 hours he felt much better. But five days before admission fever, rigors, headache, and vomiting returned; anorexia was complete; both mental and physical prostration soon became marked features; and he slept poorly or not at all. He developed a slight cough producing only scanty sputum. The day before admission he developed a sore throat.

On admission to hospital he looked seriously ill, with pale complexion, sunken eyes, and hollow cheeks. His lips were crusted with sordes, and his tongue was dry, brown, and furred. He was not dyspnoeic, and lay flat in bed without distress. His temperature was 99° F. (37.2° C.), pulse 80, and respirations 22. The fauces and tonsils were injected but no exudate was seen. The right tonsillar gland was enlarged and tender, but other lymphatic glands were normal. Bronchial breath sounds were audible in scattered areas over the right lung base posteriorly, and there were crepitations on inspiration in this area. The cardiovascular system was normal and the blood pressure 100/70 mm. Hg; the spleen was not enlarged. The central nervous system was normal except for the profound mental prostration. Questions were answered reluctantly, slowly, and with difficulty, but the answers were nevertheless clear and not confused.

Laboratory Investigations.—On Sept. 14 a radiograph of the chest revealed loss of translucency in the right lower zone, suggesting an inflammatory lesion. A psittacosis complement-fixation test was positive to a titre of 1/64. The titre rose to the level of 1/256 on Sept. 27. Blood culture was sterile aerobically and anaerobically. A throat swab revealed no haemolytic streptococci, diphtheria bacilli, or Vincent's organisms. On Sept. 15 a blood count showed: Hb, 89%; white cells, 5,400 per c.mm. (polymorphs 84%, eosinophils 1%, lymphocytes 10%, large hyalines 5%). Sputum contained many bacteria and some monilia, but no virus was seen. On Sept. 21 a radiograph of the chest showed that the lower zone of the right lung field had cleared. An irregular opacity was apparent in the left mid-zone. On Sept. 27 the lung fields were clear.

Treatment.—The history of exposure and the clinical features of the illness made the diagnosis of psittacosis certain enough to justify treatment before laboratory confirmation was available. Apart from penicillin, the only drugs used were analgesics to relieve headache and sedatives to ensure sleep. Each dose of penicillin was mixed with 1 ml. of 2% procaine to reduce the discomfort of the injection. Penicillin therapy was started in the patient's home on Sept. 13, seven days after the onset of the illness. On that day 1,200,000 units were given in three doses. On Sept. 14, the day of admission, one dose of 500,000 units and one of 1,000,000 units were given. Thereafter 1,000,000 units of penicillin were injected twice daily for four and a half days. The drug was discontinued on Sept. 19, the patient by then having received a total of 11,700,000 units.

The response to treatment was most satisfying. On Sept. 16, ten days after the onset of the illness and 72 hours after the initiation of penicillin therapy, the patient was completely apyrexial (see Chart), his mental processes were noticeably

clearer, and he was sleeping well. Next day the signs of consolidation at the base of the right lung were still present, and in addition there was clinical evidence of left basal pneumonia. These fresh pulmonary findings were not, however, accompanied by further symptoms or constitutional upset. On Sept. 19 treatment with penicillin was discontinued. On Sept. 21 a radiograph of the chest confirmed the clinical findings by showing diffuse shadowing at the left mid-zone, suggesting an inflammatory process. But by now the right base showed considerable clearing radiologically. Clinical improvement was rapid, and on Sept. 27 the lungs were normal both clinically and radiologically.

The patient was discharged, symptom-free, on Oct. 1, 25 days after the onset of the illness, and 17 days after admission to hospital.

Comment

A patient suffering from a severe attack of psittacosis is usually ill for between two and four weeks. Prognosis is difficult to assess, but the outlook is better in the young than in the old, and extensive pulmonary involvement tends to carry a high mortality. In the patient under consideration penicillin therapy was started seven days after the onset, and complete defervescence had occurred 72 hours later. In view of the severity of his illness it seemed reasonable to attribute the satisfactory response to the treatment he received.

Reported cases of human psittacosis treated with penicillin are few. Parker (1945) published details of two such patients. In the first, a woman of 61, treatment with intramuscular penicillin in a dosage of 120,000 units daily was started on the nineteenth day of the illness, and the patient had become apyrexial on the twenty-first day. The second patient was a woman of 52 who received 160,000 units of penicillin daily from the thirteenth day. She was afebrile on the sixteenth day. In the same year Flippin, Gaydosh, and Fittipoldi (1945) treated a man of 53 with 100,000 units of penicillin daily after he had been ill for 19 days. On the twenty-second day great improvement was shown. However, since in these three patients the drug was given late in the disease, when spontaneous recovery might have been expected, the improvement which followed the administration of penicillin cannot conclusively be attributed to this treatment.

In the case of a patient aged 43 reported by Turgasen (1944) a daily dosage of 100,000 units of penicillin was begun on the fifth day of the illness. But the response was not dramatic, for the patient's high fever persisted for five days after the initiation of treatment. Rosebury *et al.* (1947) reported the treatment of a man aged 41 with both penicillin and sulphadiazine: 400,000 units of penicillin were given daily from the fourth to the fourteenth day of the illness, and 6 g. of sulphadiazine was given daily from the fifth to the twelfth day. The patient became apyrexial, and marked clinical improvement was shown as early as the sixth day, after he had received 800,000 units of penicillin and only 4 g. of sulphadiazine. The dosage of sulphadiazine here seems too small for this drug to have been of major therapeutic value, and the satisfactory response must therefore probably be attributed to the penicillin.

Wolins (1948) reported six patients suffering from psittacosis, only one of whom could be considered severely ill. Four of them responded satisfactorily, though not dramatically, to 400,000 units of penicillin daily. The same dose of penicillin had little effect on the course of the illness in the remaining two. Wolins pointed out that two of the four patients who responded well to penicillin had earlier failed to improve on a smaller dose (200,000 units daily).

In contrast with the clinical evidence there is good experimental evidence that infection of the mouse with psittacosis virus can be controlled by penicillin. Heilman and Herrell (1944) infected 104 mice with psittacosis virus and treated half of them with very large doses of penicillin (1,000 units daily), the remainder acting as controls. All the controls died, whereas the mortality in the treated mice was only 8%. This finding was confirmed by Bedson and May (1945), who also showed that the minimum dosage of penicillin necessary to protect a mouse from a lethal infection was 800 units a day for four days. This again is a very large dose, and suggests that, if one may argue from mouse to man, the total dosage of penicillin needed to treat a human case of psittacosis would be about 11,000,000 units. The treatment of the case reported above was of this order.

It may be that the two most recent antibiotics, chloramphenicol and "aureomycin," which are effective against viruses of the psittacosis-lymphogranuloma group (Smadel and Jackson, 1947; Wright *et al.*, 1948), will prove more useful than penicillin. They have the added advantage that they can be given by mouth. However, neither is as yet available in this country, and in the meantime the encouraging result obtained in the case described here suggests that penicillin is well worthy of further trial in the treatment of psittacosis in man. It seems likely, however, that the dosage should always be massive; and if 2,000,000 units daily should prove ineffective an even higher dose should be considered.

I wish to thank Dr. Donald Hunter and Professor S. P. Bedson for much valuable advice and criticism. Permission to publish this account was kindly granted by Dr. Hunter, under whose care the patient was treated.

A CASE OF MONOCYTIC LEUKAEMIA TREATED WITH AMINOPTERIN

BY

P. L. de V. HART, M.B., M.R.C.P.

Clinical Assistant, Metropolitan Hospital, London

The acceleration of the leukaemic process produced by folic acid led to the search for antagonists which might favourably influence the disease. The most potent compound so far reported is "aminopterin" (4-aminopteroylglutamic acid), though others with similar properties have lately been used. It is effective in doses of 0.5–1 mg. daily in children and up to 4 mg. daily in adults. It causes a general depression of bone-marrow function and has toxic effects at therapeutic dosage which seriously limit its usefulness. It can be given by intramuscular injection, but is equally effective by mouth. In the case reported below none was available for oral administration.

Case Report

An obese man aged 30, who was subject to spasmodic bronchitis severe enough to warrant grading C2 in the Army, presented with a six-weeks history of furunculosis and stomatitis. For six months he had been listless and unduly fatigued. The stomatitis consisted of a boggy hypertrophy of the gums and hard palate. There was no bleeding, but the mouth was very painful. Neither spleen, liver, nor lymph glands could be felt to be enlarged. There was an irregular fever; the patient was anaemic, and Hess's test for capillary fragility was positive. A blood count showed: white cells 32,400 per c.mm. (monocytes

62%, lymphocytes 28%, polymorphs 10%); red cells, 2,700,000 per c.mm.; Hb, 48%. Sternal marrow puncture showed 73% of the cells to be monocytes or precursors, with numerous primitive cells. A diagnosis of Schilling-type monocytic leukaemia of subacute nature was made. The marrow counts are shown in the accompanying table.

Table Showing Marrow Counts

	Day		
	3rd	44th	62nd
Neutrophil myelocyte	5%	28%	35%
Eosinophil myelocyte			3%
Neutrophil polymorph	6%	20%	11%
Eosinophil polymorph			1%
Monocytes and precursors	73%	19%	29%
Lymphocytes	12%	9%	5%
Nucleated red cells	2%	23%	11%
"*Blasts*"	2%	1%	4%
Plasma cells	—	—	1%

Treatment was begun with fresh blood transfusions and penicillin, which improved the local sepsis and general condition. Aminopterin was first given on the thirteenth day, and an immediate improvement occurred in the peripheral blood count (see Chart). The platelets were only 37,000 per c.mm. at first, but this level was well maintained throughout treatment. There

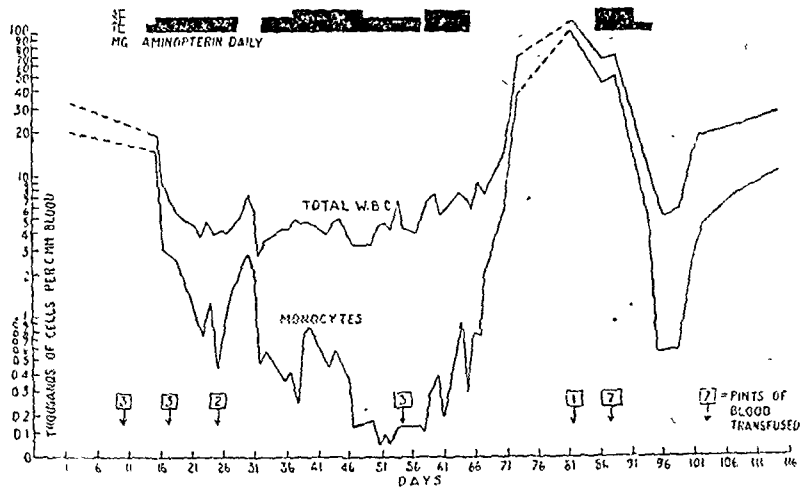

Chart showing progress of case.

was one brief intermission due to a respiratory infection, but apart from this the remission progressed until the blood picture was normal. A second sternal puncture showed a great improvement in the balance between the cells and considerable maturation.

Thirty-two days after starting treatment, when 64 mg. of aminopterin had been given, the toxic effects of the drug became manifest. Stomatitis due to painful shallow ulceration of the gums, spreading on to the lips, became steadily worse until treatment had to be stopped. A total of 109 mg. had then been given. The stomatitis rapidly healed on ceasing treatment.

A slow tendency to relapse was manifested in the peripheral blood picture even before treatment was stopped, but afterwards a rapid multiplication of the leucocytes occurred, the pathologist remarking that the blood resembled a marrow smear in the number of primitive cells involved. Between the 71st and 80th days the patient was at home, but on return to hospital the blood was found to contain 125,000 white cells per c.mm. (77% monocytes and 5% promonocytes)—a picture far more mature than during the rapid multiplication period after the aminopterin was stopped.

A second course of the drug was given, with blood transfusion; this led to a second and more dramatic remission, but the toxic effects of the aminopterin recurred almost immediately and the treatment was again stopped. Toxicity on this occasion also involved colicky abdominal pain, diarrhoea, and ulceration of the rectum. On the 103rd day, when the blood picture had again become grossly leukaemic, the patient was given a massive transfusion without aminopterin; but no improvement occurred, showing that transfusions were probably not the cause of the remissions. It was intended to follow this by a course of aminopterin without blood, but on the 113th day the patient died suddenly, almost certainly from a pulmonary embolism from a site of transfusion in the leg, although he was ambulatory up to the last. Only a limited post-mortem examination was permitted, so that it was not possible to confirm the immediate cause of death.

Comment

This case is of interest, as Dameshek (1949) was unable to produce remissions in three cases of monocytic leukaemia treated by him with folic acid antagonists, though myeloid and lymphoblastic cases responded. The readiness with which a return to maturity may be induced in the leukaemic cell with aminopterin serves to remind one that the leukaemic states are in the borderland between neoplastic and infective disease.

Leukaemic cells differ from cancer cells in that they do not show the phenomenon of aerobic glycolysis (Kempner, 1939); also they mature within 14 days when cultured *in vitro* (Israëls, 1940), whereas cancer cells multiply unchanged indefinitely. Mouse and fowl leukaemias are readily transmissible, but there is reason for suspecting that these results may be inapplicable to human leukaemia, since the disease has never successfully been transmitted in mammals other than rodents. The demonstration of marrow-stimulating substances in large quantities in the urine and faeces of leukaemic patients (Miller and Turner, 1943) suggests that the basic error in leukaemia may lie not in the leukaemic cell but in its environment. The ultimate cause of this change is unknown, and on that point it is difficult even to conjecture. But this concept provides a far more fruitful line of possible therapy, since, if the environment can be altered, useful remissions should be obtainable. Perhaps aminopterin may represent this form of approach to the problem: its effectiveness in such small quantities suggests that it may be acting on a fundamental mechanism. The efforts to obtain more effective and less toxic drugs of this nature which are now in progress are therefore amply justified.

Summary

A case of monocytic leukaemia in a man aged 30 is described in which remissions followed the administration of aminopterin. The peripheral blood count returned entirely to normal after five weeks, but owing to toxicity the drug had to be withdrawn after 109 mg. had been given, and a rapid relapse followed. A further remission was obtained by a second, shorter, course. The patient died on the 113th day from pulmonary embolus. Some aspects of this form of therapy are discussed.

My thanks are due to Dr. N. G. Hulbert, who had the patient under his care, for permission to publish this case and for his encouragement. Acknowledgments are also due to Dr. S. J. Hopkins, who was responsible for the blood counts, and to Dr. R. B. Scott and Sir Lionel E. H. Whitby, who confirmed the diagnosis; also to Professor Haddow, of the Royal Cancer Hospital, for his kindness in supplying the drug, which was manufactured by Lederle Laboratories.

ISOLATED UNILATERAL SPINAL ACCESSORY NERVE PALSY OF OBSCURE ORIGIN

A REPORT OF THREE CASES

BY

JOHN D. SPILLANE, M.D., M.R.C.P.

Physician in Charge of the Department of Neurology, United Cardiff Hospitals

Injury to the spinal accessory nerve during operation for block dissection of cervical glands is probably the commonest cause of unilateral paralysis of the sternomastoid muscle. In the neck the nerve may be injured by direct compression from enlarged glands and from tumours or abscesses, and of course it may be damaged in penetrating wounds. Within the skull, in the posterior fossa, it may be involved in tumour, abscess, or aneurysm formation. Occasionally a syphilitic process within the skull may implicate the nerve as it runs from the foramen magnum to the jugular foramen. Within the spinal cord or medulla the cells of origin of this exclusively motor nerve are not infrequently involved in degenerative processes such as motor neurone disease and syringomyelia. The same cells are also liable to destruction by the virus of anterior poliomyelitis.

The sternomastoid and trapezius muscles often undergo atrophy in the muscular dystrophies and especially in the affection called myotonia atrophica.

During the past five years I have encountered three patients in whom the sole lesion was an isolated spinal accessory nerve palsy. Weakness and wasting of the sternomastoid muscle and of the upper fibres of the trapezius on the same side were the only abnormalities.

Case 1

A soldier aged 25, serving in the Middle East, was referred to hospital as a possible case of "shoulder-girdle neuritis" (Spillane, 1943). He had always enjoyed good health, but for a year past had been troubled with an aching pain about the right shoulder. This was never acute and did not involve the arm. It was ill defined and dull in character, nearly always following prolonged exercise. He had noticed that his neck was asymmetrical.

FIG. 1.—Case 1. Wasting of sternomastoid muscle and upper fibres of trapezius on right side. Tilt of head to right suggests that the lesion is of long standing.

There was considerable wasting and weakness of the sternomastoid and upper part of the trapezius on the right side. The right shoulder had dropped (Fig. 1). The nervous system was otherwise normal. *X*-ray examination of the skull base and cervical vertebrae revealed no abnormality. The C.S.F. was normal, and the Wassermann reaction in the blood and C.S.F. was negative.

During his stay in hospital repeated questioning and examination disclosed nothing to suggest that the problem was one of early myotonia atrophica.

Case 2

A soldier aged 31, serving in the Middle East, was similarly referred to hospital because of pain about the neck and right shoulder and obvious asymmetry. His past clinical history revealed nothing of note, and there were no other complaints. He said his right shoulder had not "felt right" for some years, but he had never had any acute pain and his right arm was normal.

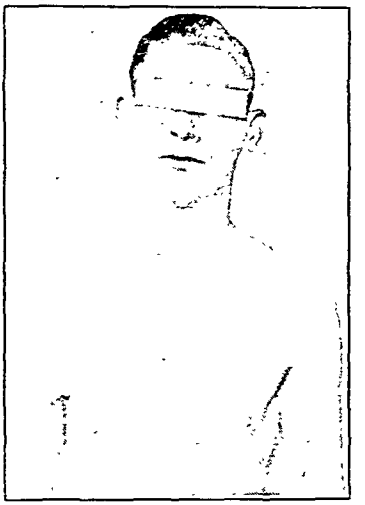

FIG. 2.—Case 2. Wasting of sternomastoid muscle and upper fibres of trapezius on right side. Considerable dropping of right shoulder.

The right sternomastoid muscle was apparently absent. There was considerable weakness and wasting of the upper fibres of the trapezius muscle on the same side, so that the right shoulder had dropped considerably (Fig. 2). There was no other abnormality in the nervous or the muscular system. *X*-ray plates, as in Case 1, showed nothing abnormal. Serological studies were negative.

The patient was detained in hospital, but no clue to the nature of the condition was forthcoming. His family history contained nothing relevant.

Case 3

A married housewife aged 30 who had never left this country was referred to me in 1946 because she complained that "there was something wrong with my neck." She was an intelligent and healthy young woman and said that at the age of 24 she had had acute pain on the left side of her neck. It prevented her sleeping and persisted for about one month. She consulted her doctor; he found local tenderness and believed that it was some form of fibrositis. During that month, however, she also had another symptom. This consisted of periodic tic-like movements of the head on the neck. Many times a day, for a few moments at a time, her head would tilt quickly, quite involuntarily, to the left. The whole condition seemed to have subsided spontaneously.

For several years she had forgotten the affair until her husband noticed some asymmetry about her neck when she wore an evening dress. That was in 1943 or 1944. In 1945 she either became self-conscious about it or the asymmetry was more noticeable, for she consulted a doctor. She had also found that certain movements were difficult from some positions. If she lay on her right side in bed and wished to raise her head she experienced particular difficulty.

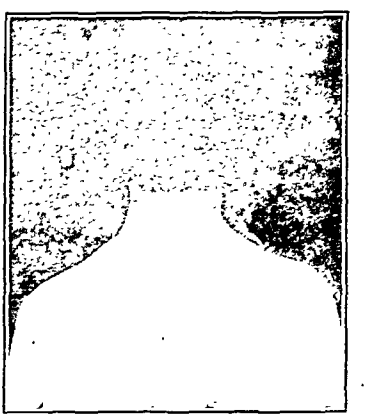

FIG. 3.—Case 3. Wasting of sternomastoid muscle and upper fibres of trapezius on left side.

She sometimes slept without a pillow, and then had some difficulty in raising the head. These symptoms, she stressed, were slight.

On several examinations the only abnormalities to be detected were identical with those found in Cases 1 and 2 (Fig. 3). The sternomastoid muscle and the upper fibres of the trapezius on the left side were noticeably weak and wasted. The nervous and muscular systems were otherwise normal. Faradic responses were not elicited from the left sternomastoid; only weak contractions were obtained from the upper part of the trapezius. Radiographs of the cervical spine and skull were normal. The blood Wassermann reaction was negative.

During the past two years she has been under my observation and no further signs have developed. Her condition is apparently stationary. Two brothers have been examined, and they present no abnormality. Both parents are dead and neither had any disability to suggest myotonia atrophica. She has inquired of cousins and other relatives, with negative results.

Aetiology

In each case all the known causes for such a lesion were considered, but the aetiology remains obscure. In the first two cases the story did not conform to the very characteristic sequence of events in the affection of neuritis of the shoulder girdle. Sternomastoid atrophy has not been recorded in that condition (Spillane, 1943; Parsonage and Aldren Turner, 1948).

The selective nature of the wasting strongly suggests that the lesion is neuritic and not muscular. There was no other abnormality; on careful examination neighbouring muscles were found to be normal.

If the nerve lesion is in the nature of a "neuritis" its causation remains unknown. Cervical adenitis would be unlikely to result in such severe atrophy. Surgeons have often commented on the manner in which the spinal accessory nerve escapes injury in suppurative conditions of the neck. Like the facial nerve the spinal accessory nerve is purely motor in function, but it does not emerge from the skull through a small foramen alone as does the former nerve. It enters the neck accompanied by the jugular vein and by the ninth and tenth cranial nerves through a relatively ample aperture. A lesion at this point would also be likely to involve these nerves.

Poliomyelitis is often suggested, especially in orthopaedic clinics, when the problem arises of explaining an isolated paralysis of one or more muscles. But in this series of cases there is certainly no positive evidence in that direction. From the accounts given by the patients the likelihood of congenital deficiency of the sternomastoid muscle is very remote.

Bilateral atrophy of the sternomastoid muscles is, of course, a usual finding in myotonia atrophica. But the other features of this disease—myotonia, general weakness, diffuse muscular pains, baldness, testicular atrophy, cataract, absent deep reflexes, and reduced vibration sense in the lower limbs—were entirely wanting. Maas (1937), however, has noticed unilateral wasting of one sternomastoid muscle in apparently healthy relatives of patients afflicted with this heredofamilial malady. One of his published photographs is very similar to that of Case 2. I have been interested in the condition of myotonia atrophica for some years, and inquiry and examination in the present series were conducted with this condition in mind. No evidence of the disorder was present—if one excludes the atrophy of the muscle fibres supplied by the spinal accessory nerve. In Case 3 it was also found that the electrocardiogram was normal. This may be of interest in view of the recent evidence that low-voltage P waves, prolongation of the P-R interval, and slurring of the QRS complex have been noted in myotonia atrophica (Evans, 1944; Heard and Spillane, in the press).

One may ask whether these cases are examples of the same disease. Although there is no definite proof, it is tempting to assume that they are. The only clue to causation lies in the story of Case 3. She had acute pain in the left side of the neck six years previously and for a time was troubled with spasmodic contractions of the left sternomastoid muscle. The affected area was tender and her doctor diagnosed "fibrositis." This sequence of events was followed by wasting of the muscle. It seems, therefore, that originally there was an irritative lesion of the spinal accessory nerve on that side.

A search of the literature has not disclosed any reports of such a condition, but isolated unilateral hypoglossal-nerve paralysis has been described. The lesion was thought to be due to a periostitis of the anterior condyloid foramen analogous to the lesion of the stylomastoid foramen which may be responsible for Bell's palsy (Goldenberg and Sandler, 1931).

Summary

Three cases are reported in which there was isolated wasting and weakness of one sternomastoid muscle and the upper fibres of the trapezius muscle on the same side.

The cause is not known, but it is probable that the lesion was in the spinal accessory nerve.

The lesion may be similar to that in Bell's palsy.

A CASE OF DIAPHRAGMATIC HERNIA OF CONGENITAL ORIGIN WITH PERFORATION OF STOMACH

BY

SIDNEY B. RADLEY, F.R.C.S.

AND

H. P. GOLDSMITH, M.B.

(From the Newark Town and District Hospital)

The following account of a complete right-sided thoracic stomach with a perforated pyloric ulcer is of interest because of (1) the extreme rarity of such a condition—we have found no other recorded case of a similar character; (2) the absence of any previous serious disability—in fact, he was able to earn his living as a general labourer, which involved considerable physical exertion and produced no pulmonary or acute digestive disturbance; (3) the opportunity of seeing and feeling the position of the various organs at operation; and (4) the complete absence in convalescence of any symptoms of discomfort, either above or below the diaphragm.

Case History

At about midnight on Oct. 25, 1948, a man aged 29 was suddenly taken ill with acute abdominal pain, which started at the centre of the abdomen around the umbilicus. It persisted and was extremely severe. He felt sick and vomited once before his admission to Newark Town and District Hospital.

Four years previously he had had "gastric trouble"—pain and fullness in the epigastrium about half an hour to one hour after food, followed by vomiting, which brought relief

immediately. His own doctor treated him by diet and alkalis, and the condition subsided after three weeks. Since then he occasionally had a mild recurrence of his epigastric pain for which he did not attend his doctor; he had not adhered to the diet prescribed. He had had no pain before the onset of his present illness. For the last five years he has been having mild attacks of "asthma," which were worse on the hot days of summer. The attacks did not prevent him from doing his work, and he has not received treatment for them.

On examination the temperature was 97.4° F. (36.3° C.), pulse 88, and respirations 26. He was well nourished. He seemed to be in pain but not shocked, and was rather excited. His tongue was moist and slightly coated. General abdominal rigidity was present, but no real tenderness; there was no reduction in liver dullness or any rebound phenomenon. No tenderness was felt per rectum. Respirations were mainly thoracic and wheezy in character. There was slight dullness at the right base posteriorly on percussion, and breath sounds were wheezy all over the chest. The pulse was regular and of good volume. The heart was not enlarged and there were no murmurs. The blood pressure was 130/84. No appreciable disease was found in the central nervous system.

Perforated gastric ulcer was suspected, and in view of the normal temperature and pulse and the patient's general condition it was decided to treat him conservatively under observation. A kaolin poultice was applied to his abdomen and he was put in Fowler's position. A half-hourly pulse chart was kept. At 5 a.m. the temperature was 99.8° F (37.7° C.), pulse 90, and respirations 24. At 7.30 a.m. the temperature was 100.6° F. (38.1° C.). pulse 112, and respirations 24. The pulse chart showed a rise from 90 to 112 between 5 and 7.30 a.m.

He was re-examined at 7.30 a.m. and his abdomen was found to be still rigid, with generalized tenderness and rebound phenomenon, and in view of his rising pulse and temperature laparotomy was decided upon.

Operation.—At 9 a.m., under anaesthesia induced by thiopentone followed by gas and oxygen and ether, a supra-umbilical paramedian incision was made and free fluid was found on opening the peritoneal cavity. On exploration the stomach was found to be entirely in the right thoracic cavity. It was in a complete peritoneal sac. There was a small hole under the liver in the right side of the crus of the diaphragm. This opening was a definite rounded orifice admitting three or four fingers. Through it, it was possible to trace the duodenum and pylorus. With peritoneal forceps passed through the opening the stomach could be grasped and pulled slightly downwards, but it could not be drawn through the aperture. A small perforation was identified by tracks of lymph and effusion, and it was closed by passing a needle on a holder through the aperture and making a purse-string suture, covering it with an omental graft from the greater curvature omentum. The liver was very prominent in the wound and seemed to be displaced downwards. It had to be retracted upwards to expose the gap in the diaphragm. When this was done there was a clear view of the opening, which was situated in the right crus of the diaphragm behind the liver and to the right of the vertebral column. A drainage tube was inserted through a separate suprapubic stab wound and the abdomen was then closed in layers.

The patient stood the operation quite well, and was in fair condition when taken from the theatre. Immediately on his return to the ward 5% glucose-saline intravenously was started. The 5% glucose saline was given intravenously for the first 48 hours. A Ryle's tube was passed and the stomach aspirated every two hours. Then he was given glucose water and citrated milk by mouth. This was gradually increased until at the end of the first week he was put on the first week of Sippy's diet. He tolerated his feeds well, and Meulengracht's diet was given at the middle of his second week. His temperature and pulse were raised for the first week; this was ascribed to pulmonary complications after anaesthesia. It subsided after treatment with penicillin injections and inhalations. His temperature and pulse have been normal since that time.

On Nov. 16 a screening examination and a series of skiagrams showed a complete thoracic stomach on the right side of the thorax and confirmed that the stomach is above the diaphragm and is lying centrally between the anterior and posterior walls of the chest. It is in a complete peritoneal sac, separated from the pleural cavity by omental tissue, peritoneum, and the basal pleura. Screen examination showed full movement of the left diaphragm and slight movement of the right diaphragm. The stomach, the greater curvature of which is uppermost, appears to empty from the right side. The duodenum passes across and behind the base of the stomach to empty through the aperture in the medial side of the right diaphragm. A film taken on Nov. 17 showed the colon displaced to the left side. This is probably due to the downward displacement of the liver.

By the sixth week he was convalescent and was able to take light diet without any discomfort or digestive trouble. He looks and feels extremely well and has returned home.

Comment

This is a case of complete thoracic stomach with a short oesophagus of congenital origin, hence the failure of the attempt to draw the stomach through the opening in the diaphragm at operation and the absence of a sliding stomach at the radiological examination under the screen when in the vertical position, which may occur in some cases.

It is completely enclosed in a peritoneal sac separating it from the pleural cavity. Unfortunately at operation it was not possible to feel the junction of the oesophagus with the stomach, so we cannot say whether the peritoneum was

Radiograph showing stomach on right side of thorax above the diaphragm. The greater curvature is uppermost. Barium is in the oesophagus.

reflected on to the stomach before it reached the cardiac orifice or whether it enclosed the cardiac end of the oesophagus.

As a result of the complete peritoneal sac there was no infection of the pleural cavity from the peritonitis after operation.

The stomach is completely rotated, with the greater curvature uppermost, and the oesophagus curves underneath the cardiac end of the greater curvature to reach the cardiac orifice. There is no stricture or hour-glass contraction, as it is a completely thoracic organ and no portion is nipped by the diaphragm, hence the absence of gastric fullness and distension.

We wish to express our thanks to Sir Thomas Dunhill for his interest in the case, for his great kindness in corresponding with us about it, and also for his account of the condition in the Arris and Gale Lecture delivered by him to the Royal College of Surgeons in 1934, from which we have derived much information. We are also indebted to Dr. F. M. Gordon and Mr. R. J. Walls, M.S.R., for the radiography.

Medical Memoranda

Traumatic Perforation of the Bladder

An unusual case of traumatic rupture of the bladder in a man suffering from schistosomiasis in South Central Africa is described below.

CASE HISTORY

A male African, judged to be about 65–70 years of age, was brought in dead to the Gwelo Native Hospital on July 2, 1948. The relatives stated that the man had died at his kraal the previous afternoon. Four days before his death, while coming out of a native hut, he had collided with another native who was entering, and the latter's head had struck the old man in the abdomen. During the four days before his death he had complained of abdominal pain and had vomited once or twice. The other natives had not brought him to hospital.

Post-mortem Examination.—At 10 a.m. on July 3 a post-mortem examination was carried out. As it was the cold season and rigor mortis was beginning to pass off, it was estimated that he had died 36 to 48 hours previously. There was no bruising of the abdomen or any other sign of injury. The presence of some vomitus in the mouth was noted. On opening the abdomen the peritoneal sac was seen to be full of a dark-brown fluid which smelt like urine. There were flakes of pus covering the coils of the small intestine, and several loops of these were adherent. The stomach, spleen, liver, gall-bladder, and small and large intestines were removed, and apart from distension and inflammation of the bowel no abnormality was detected. Examination of the bladder *in situ* revealed a hole in the fundus about the size of a sixpence. The bladder was empty. The edges of the hole were ulcerated and sloughing. The bladder was carefully removed and opened. The prostate (median lobe) was seen to be much enlarged, and the mucosa of the bladder had the granular appearance and ulcerated areas seen in extensive schistosomiasis. The kidneys and ureters were removed, but they showed no naked-eye pathology.

Histology.—A snipping of mucosa close to the hole in the bladder was examined microscopically by teasing out the preparation in water on a slide. The mucosa was seen to be packed with terminal-spined ova (*Schistosoma haematobium*). Section of a portion of the ulcerated edge of the vesical perforation showed the presence of *S. haematobium* ova in large numbers in the mucosal layer and some leucocytic infiltration of the deeper muscular layers.

COMMENT

From the above findings it was concluded that in the presence of a distended bladder, presumably in part due to the enlarged prostate gland, the blow on the abdomen had caused rupture to take place through the most advanced area of schistosomal destruction. The resulting extravasation of urine caused a generalized peritonitis, ending in death from the toxaemia.

This case is described for two reasons. First, enlargement of the prostate gland is not a common condition in the Africans of Southern Rhodesia, presumably because of their death at a somewhat early age. Secondly, although the presence of schistosomal infection is extremely common in the South Central African native (Gelfand and Ross), I can find no evidence in the literature of a previous traumatic rupture of the bladder through such an area.

Although this native must have been suffering considerable pain during the four days previous to his death, he was not admitted to hospital, which was in the near vicinity of the accident. This may have been due to a disinclination of the other natives to reveal the accident, but may be an example of the remarkable stoicism of the native in the presence of severe pain. The relatives definitely stated that in the first two days of his illness the old man was working in the fields.

Grateful thanks are due to Dr. G. R. Ross, Acting Secretary for Health, Southern Rhodesia, for permission to publish this case.

W. FRASER ROSS, M.B., Ch.B., B.Sc.,
Government Medical Officer, Southern Rhodesia.

A Case of Femoral Appendicitis

A rare complication of femoral hernia occurs when its sole content is the vermiform appendix. An example of this is considered worth recording.

CASE REPORT

The patient, a woman aged 55, was seen at a gynaecological out-patient clinic on Oct. 8, 1947. Three weeks previously she had developed a feeling of heaviness at the "bottom of the stomach." Five days later she noticed a lump in the right groin, and shortly afterwards she began before micturition to feel slight pain, which persisted. Her history was otherwise negative.

On examination the internal group of superficial inguinal glands in the right groin were found to be tender and inflamed. There was slight inflammation of the urethra, and a few sub-epithelial haemorrhages were present in the vestibule. The glands were treated by local applications for a week, and on re-examination on Oct. 15 the acute infection had settled. The hard irregular lump had persisted, and the glands were slightly movable, discrete, and hard. No femoral hernia was palpable, and arrangements were made to remove a gland for biopsy.

On Oct. 17 the patient was operated on under local analgesia. Dissection revealed a lobulated fatty mass with two normal lymphatic glands perched on its surface: the mass extended towards the femoral ring. The sac was opened and was found to contain turbid fluid surrounding a purple pre-gangrenous vermiform appendix. The appendix was removed and the stump allowed to retract into the abdomen. The inguinal canal was then opened, and the femoral sac was transposed above the inguinal ligament, where it was excised. One stitch between inguinal ligament and pectineus fascia was adequate for the repair of the small femoral ring. Closure of the aponeurosis and skin was then effected without drainage.

No pathological examination was considered necessary either for the glands, which were macroscopically normal, or for the appendix. Convalescence was uneventful.

DISCUSSION

In 1731 De Garengot recorded the first operation for hernial appendicitis, and in 1785 Hevin gave the first detailed description of operation for femoral appendicitis. Ryan (1937) published three cases of femoral appendicitis, Watson (1938) collected 217 cases, two cases were recorded by Seley (1941) and one by Knapp and Claps (1944), bringing the total number of published cases of this condition to 223.

The most unusual case recorded is that of Johnstone (1934). In his case auto-appendicectomy occurred, and was followed by survival of the separated appendix owing to the acquisition of a new blood supply from the wall of the hernial sac.

Battle (1899) has recorded a case of appendicitis in a femoral hernia associated with inflammation of the overlying glands, and this is the only case found in the literature similar to the present one.

The sustaining interest of femoral appendicitis would seem to be, first, that it is so rarely diagnosed pre-operatively, and, secondly, the difficulty in making a precise

diagnosis even when the possibility of its occurrence has been remembered. Taking the present case as an example, the data on which an accurate diagnosis could be based were quite inadequate: it was not even possible to be sure that a femoral hernia coexisted with the inguinal glands. Furthermore, even when a hernia is obvious, the differential diagnosis of femoral appendicitis is most difficult. One must exclude omental hernia, partial enterocele, adenitis, strangulated epiploic appendix, prehernial lipoma, intestinal diverticula in hernia, and reducible and irreducible hernia of the intestine, bladder, and other viscera. It seems obvious that in most instances this condition is destined to remain an accidental finding during herniotomy.

I am indebted to Dr. C. E. B. Rickards, honorary gynaecologist, Warrington Infirmary, for permission to publish this case.

An Interesting Case of Epilepsy

The following case is worth reporting because of several unusual features. It also emphasizes one of the pitfalls of psychiatric practice and closely links up neurology and psychiatry.

CASE HISTORY

A male aged 30 was transferred to us from a hospital in the Midlands where he had been suffering from partial aphonia, difficulty in swallowing, and attacks of partial unconsciousness for several months.

History of Present Illness.—His first fit occurred at the age of 17, while he was at his fiancée's house. There was no recurrence until soon after marriage, at the age of 21. During these attacks he threw his arms and legs about, and after a severe attack found it difficult to walk. After being turned down by several medical boards he was finally accepted by the Army, but about three weeks later, while waiting to go overseas, he had one of his fits. On account of this he was invalided out.

He continued to have four or more fits daily for several months after his discharge. Gradually the fits became less frequent and their nature changed to what the patient's relatives described as "blackouts," in which his head suddenly dropped on his right shoulder, he appeared to lose consciousness for about two minutes, and then suddenly recovered. During these attacks he bit his tongue if no precautions were taken. In neither these "blackouts" nor the fits was he ever incontinent.

Early in 1947 he developed a progressive impediment in his speech and had difficulty in swallowing both liquids and solids. This led to his admission to the Midlands hospital, where, after some months' treatment, a psychiatrist was consulted. He came to the conclusion that the patient's condition was "in many ways a regression to infantile behaviour. It would appear that the epileptic element in his condition has receded and been largely replaced by hysterical regression." On account of the frequent fits the patient had been unable to work for four years. There was no history of epilepsy in his family and nothing significant in his early medical history.

Condition on Admission.—A well-nourished young man. Because of tonic spasm of the masseters the patient could not open his mouth wide and could only lisp like a child. There was continuous dribbling of saliva owing to difficulty in swallowing. There were no other physical signs.

Investigations.—Wassermann negative. Total R.B.C. 5 million, Hb 100%, C.I.=0.9.

Progress.—While under observation in the ward he had several fits, both when awake and when asleep. Fits could also be easily induced by hypnotic suggestion, and clinically there was no difference between spontaneous and induced fits. Each fit began with the typical epileptic cry, followed by tonic contraction of facial muscles and loss of consciousness for one to two minutes. At the same time the head dropped to the right side. During the attack the plantar reflex was extensor on both sides. Cyanosis of the face varied—sometimes it was marked, at other times it was slight or absent. During a demonstration it was possible to induce by post-hypnotic suggestion a series of these fits in rapid succession when the patient was standing but supported on either side. There was difficulty in obtaining the E.E.G. record owing to the number of fits, the tracing being "grossly abnormal; high amplitude slow rhythms between attacks, definite evidence of epilepsy." Next day he had fits almost every 10 minutes—a total of about 132 fits in 24 hours—although he was receiving phenobarbitone gr. 1 (65 mg.) t.d.s., and epanutin (soluble phenytoin) gr. 1½ (0.1 g.) b.d. Although lucid in the intervals, he was unable to open his mouth; the muscles of his neck and nasopharynx also appeared to be in spasm, as it was difficult to pass a feeding-tube. In order to control the fits he was given paraldehyde dr. 8 (28 ml.) per rectum, but he rejected a good deal of this. However, phenobarbitone sodium, 1 ml. intramuscularly, and "amytal," gr. 3¾ (0.25 g.) intravenously, caused sufficient relaxation of the pharyngo-oesophageal muscles to enable him to swallow. He was then given phenobarbitone gr. 2 (0.13 g.) t.d.s. and epanutin gr. 3 (0.2 g.) b.d., which reduced the fits to 23 in 24 hours. In spite of these large doses of phenobarbitone and epanutin he had 17 fits next day. He was then seen by a neurologist, who considered there was an approximation to status epilepticus. During the next 24 hours the patient had only seven fits, although there was considerable tonic spasm of the jaw muscles. Next day (26th day after admission) he had no fits, but the dribbling continued. The E.E.G. showed "great abnormality of the cortical rhythms from all areas of the head, possibly more so on the left side. Diffuse 3 c/s and 5/6 c/s rhythm. little alpha rhythm seen; 3 c/s rhythms often occurring in bursts of high amplitude. Blocking by visual stimuli poor." From that day he had no spontaneous fits and suggestion failed to induce them (although there was no change in his domestic circumstances). The increased salivation, however, did not respond to any treatment and persisted for several days. An E.E.G. performed just before his discharge from hospital showed: "Generalized abnormality of 5–6 c/s rhythms. Still some 3 c/s rhythms present, but not having the high amplitude of the previous recordings. Some alpha rhythm seen of 8 c/s, blocked by visual stimuli. No single focus of abnormality seen. Record greatly improved." On discharge from hospital he was able to start work, and was later reported to be still employed.

DISCUSSION

There is no doubt that this was a genuine case of epilepsy involving specially the face and the pharyngo-oesophageal region. Psychogenic causes were apparently sufficient to initiate the attacks, thus lending support to the concept of hystero-epilepsy. Fits which were clinically indistinguishable from epileptic attacks could also be induced by hypnotic suggestion, though they could not be controlled by suggestion. The E.E.G. records showed that the induced fits were identical with epileptic fits. The reponse to phenobarbitone and epanutin was also significant.

SUMMARY

A case of epilepsy involving the face and pharyngo-oesophageal region is described. The fits were initiated by psychogenic causes.

Thanks are due to the medical superintendent for permission to publish the case-notes.

VIRUS DISEASES OF MAN

Viral and Rickettsial Infections of Man. Edited by Thomas M. Rivers, M.D. (Pp. 587; 77 illustrations, including 6 plates in colour. 45s.) Philadelphia and London: J. B. Lippincott Company.

It is nearly fifty years since a virus was first demonstrated as the cause of a human disease, yellow fever. During these fifty years, and especially during the last two decades, a vast amount of knowledge has been acquired, and to-day there fall to be discussed in this work no fewer than fifty-four virus infections to which man is susceptible. Even then, two diseases are omitted: the recently described but somewhat unfortunately named "Mengo encephalitis" (Mengo is a place name and has nothing to do with the meninges), and Durand's disease, which was found in Tunis in the early days of the war. The latter undoubtedly deserves mention.

Within the past few years there has been a stabilization of our knowledge and ideas of virus and rickettsial infections, and it is opportune that these advances should be collected and made easily accessible to all those interested, whether or not they are actively engaged in the study of virus and rickettsial infections. As it would obviously be impossible for one person to write authoritatively on all these diseases and their causal agents, Dr. T. M. Rivers, the editor of this co-operative venture, has been assisted by twenty-seven collaborators, comprising all the best-known virus and rickettsial workers in America. After a short introduction on the general aspects of viral and rickettsial infections by the editor, there are chapters on physical and chemical procedures by W. M. Stanley and M. A. Lauffer, serological reactions by J. E. Smadel, chick embryo techniques by E. W. Goodpasture and G. J. Buddingh, tissue culture procedures by J. F. Enders, and epidemiology by K. F. Maxcy. The inclusion of a chapter on bacteriophages is of value but requires explanation, for bacteriophages never give rise to human infections. In one or two places in these introductory chapters there is a somewhat uneven distribution of emphasis. Variation in viruses is dismissed in less than half a page, but four times this space is given to the question of variation in bacteriophages. The same criticism may be urged against the space allotted to the interference phenomenon as applied to bacteriophages and to other viruses. Bruce White's original description of the interference phenomenon in bacteriophages is unmentioned.

Each virus and rickettsial disease is described under the following heads: definition, history, clinical picture, pathology, aetiology, diagnosis, treatment, and epidemiology. In the majority of cases the articles are excellent, and are written by those who have actually contributed to our knowledge of the particular infection they describe. The book thus represents a vast storehouse of facts up to 1946, and it should undoubtedly be read and digested by laboratory workers, clinicians, and epidemiologists alike. If any criticism is possible it is that American workers have failed to appreciate fully work carried out on viruses in Europe before and during the war. In the chapter on the hepatitis viruses, for instance, it would be difficult to deduce that their nature was well appreciated before 1940. There are, however, other than purely medical reasons for glossing over some of these facts.

The book is beautifully produced and well illustrated. An excellent coloured plate by Leon Schlossberg shows the reactions to vaccinia vaccination in both white and coloured persons. These illustrations will be intensively studied, though some of the other coloured plates are less successful. Adequate author and subject indexes are provided. A work of this type has obviously cost much to produce, and it is only through a grant from the National Foundation for Infantile Paralysis, Inc., that its publication has been possible. Virus workers in dollar-starved countries owe a further debt to the National Foundation for Infantile Paralysis in that it has made copies freely available to them. In 1783 Dr. Benjamin Rush wrote to Dr. John Lettsom in London to thank him for sending medical books from England. "I have feasted on each of your pamphlets," he said. "It is an act of Charity to pour upon a benighted American the discoveries of the last eight years in Europe." One hundred and fifty-six years later America has fully repaid her debt.

G. M. FINDLAY.

MYCOLOGY

Mycoses and Practical Mycology. By N. Gohar, M.R.C.S., L.R.C.P. With foreword by Sir Philip Manson-Bahr. (Pp. 234; 4 colour plates and 134 other illustrations. £1 5s.) London: Baillière, Tindall and Cox. 1948.

In his foreword to this work Sir Philip Manson-Bahr truly describes mycology as the Cinderella of modern medicine. Dr. Gohar is to be congratulated for having had the courage to attempt so comprehensive a task as preparing this book, and has succeeded in presenting a balanced picture of the whole range of medical mycology in a small and compact volume. The major mycological diseases as they affect the patient as a whole, and the more important affections of the separate systems, particularly of the respiratory and digestive tracts and the skin, are briefly but clearly described. The difficult problems of mycology, the morphological and cultural details, and terminology are discussed adequately but in simple and lucid style. The approach is modest, the presentation is capable of easy interpretation, and Dr. Gohar is fortunate in having the ability to incorporate the mycological studies as part of the whole clinical problem of diagnosis and treatment. There is a brief but interesting historical introduction to many of the major subjects which adds to the pleasure to be derived from reading this work.

The book is pleasingly produced, paper and typescript are good, and illustrations are plentiful and helpful. There are very few errors in the text, and the author has an attractive style.

The volume is particularly valuable to the dermatologist, and the section describing the dermatomycoses is admirably presented. It is not possible to satisfy all authorities in such a difficult and contentious subject, and if criticisms are offered it is only that they may be considered in preparing further editions of this book, which will certainly be expected as mycology receives more adequate recognition. The chapter on epidermophytosis is good except for the section on treatment, which is inadequate and makes no reference to the value of modern fungicides. In other parts the clinical descriptions and differential diagnosis could be elaborated with advantage. More comment upon modern fungicides and bases would have been interesting. Treatment in recent years has advanced rapidly, and this is not always reflected in the text. There is a tendency to indicate past and present therapeutic measures in rather colourless fashion, without emphasis or indication of their relative values. In the description of actinomycosis and erysipeloid infections the reader would not suspect from the text that penicillin has revolutionized treatment in these fields.

The section on diagnosis and treatment of ringworm infection of the nails could be improved, and Dr. Gohar is unduly pessimistic. The paragraph devoted to "phytid" reactions is too brief and inadequate. A kerion ringworm lesion is a pustular reaction to the ringworm fungus itself and not a secondary pyogenic infection superimposed upon the fungus, as suggested. In the paragraphs on black hairy tongue there is no reference to its occurrence as a sequel to sucking penicillin lozenges. The chapter on fungicides is incomplete and has no mention of the dyes, of dithranol, or of the modern fatty-acid preparations.

But these are small points relative to the value of the work as a whole. It promises to become a valuable textbook on this subject, of great help to the student and practitioner in every branch of medicine, but it will be particularly well received by the student of dermatology. It is surprising that this field has been so sadly neglected by the laboratory and research worker, and it is to be hoped that this book may

stimulate others with the necessary training to pursue further the investigation and research which are so necessary in medical mycology.

J. T. INGRAM.

ADVANCES IN OPHTHALMOLOGY

Documenta Ophthalmologica. Edited by F. P. Fischer, A. J. Schaeffer, and Arnold Sorsby. Vol. 2. (Pp. 462; illustrated. No price.) *Holland*: W. Junk. 1948.

The second volume of this series (which periodically summarizes recent advances in ophthalmology) contains seven articles of more than usual interest. A study on physiological optics by A. von Tschermak deals with several problems. The first describes a "contrastometer" to demonstrate the compensating reaction on simultaneous contrast in the retina of frogs, the illumination of which can be varied by polarization. The entoptic phenomenon of Heidinger's brushes is then considered, with an interesting discussion on the effect of double polaroid spectacles in reducing the light entering the eye. The discrimination curves of photopic and scotopic vision are described in terms of wavelength and oscillation frequency, and the basis of stereoscopic vision is reviewed as it originates on retinal points in which size relations differ. It is finally shown that the coincidence of entoptic and exoptic stimuli may result in monocular diplopia.

The physiological optics of the visualization of *x*-ray pictures are discussed by W. Bronkhorst, J. Ten Doesschate, and F. P. Fischer, who bring forward some points of considerable interest which have hitherto been largely ignored by radiologists. R. Weekers and F. Roussel contribute an article on the critical frequency of fusion, particularly in its relation to pathological conditions. They point out that the physiological variations of this factor are small, while pathological anomalies produce marked disturbance. Thus, in cases of detachment of the retina the pre-operative extent of the detachment and the functional defect can be estimated with considerable accuracy. In tobacco amblyopia the critical frequency is reduced in the centro-caecal area in proportion to the degree of intoxication; in glaucoma, disturbances in the frequency are early and common, and may supplement perimetric studies.

J. Ten Doesschate and F. P. Fischer contribute an article of considerable length on the mechanical properties of the tissues of the eye, emphasis being placed on their micellar structure; the bearing of this work, which may seem academic in nature, is of importance in such conditions as detachment of the retina.

Two papers are contributed by G. Karpe, of Stockholm, the first a description of his own apparatus for recording the electro-retinogram in clinical cases, and the second the application of this relatively new method in the investigation of cases of ocular siderosis. Electro-retinography can be used to follow the course of development of siderosis, and Karpe has found that it provides information of great value when the difficult decision has to be made upon the advisability of undertaking a dangerous operation for the extraction of a foreign body which has been in the eye for some time. It is interesting that in the initial stages of this disease both the positive and negative components of the electro-retinogram are increased at a stage when the disease cannot yet be recognized by the usual clinical examination, while at a later stage the retinogram becomes negative and is finally abolished, even though the retina may function reasonably well. The potentialities of this new clinical method are therefore considerable.

The final section by L. Poleff, of Rabat, deals with recent work on trachoma. He gives a general review of the state of our knowledge of the aetiology of this disease, based on morphological studies and the results of culture experiments and of inoculations carried out in animals and man, adding a discussion on the virus and rickettsial nature of the infective agent, the significance of the Weil-Felix reaction, and questions of immunity and predisposition. The discussion is critical, and it is pointed out that many problems are yet unresolved.

The book, in which the various articles are written in German, French, and English, deals with the more scientific developments of ophthalmology, which are not readily obtained elsewhere, and is of considerable interest and value.

STEWART DUKE-ELDER.

HEART DISEASE

Cardiology. By William Evans, M.D., D.Sc., F.R.C.P. (Pp. 310; illustrated. £1 15s.) London: Butterworth and Co. 1948.

Dr. William Evans has set out very effectively, though rather dogmatically, the facts and arguments upon which the diagnosis and treatment of heart disease are based. The work is founded upon a series of lectures, from which it derives a note of personal experience; at the same time it is inevitable that it should bear some of the disadvantages of such an origin.

The merits of the work are so obvious that it is unfortunate the author has at times allowed personal views to be presented as final judgments. For example, there is no general agreement that the term "triple rhythm" should replace "gallop rhythm," and, since most cardiologists are resolved that "gallop rhythm" shall stay, the term should at least find mention in a standard textbook. We know that ordinarily there are two heart sounds, just as there are two phases of respiration; if there is a third sound it may or may not be of pathological significance. While the term "triple rhythm" might suitably denote the innocent form of this auscultatory phenomenon, it would be better to preserve for the pathological sign the descriptive and honoured term of "gallop rhythm." To speak of "the fourth heart sound" is, to say the least, confusing.

It is regrettable that Dr. Evans has given room in this book for consideration of so complex a subject as the classification of auricular tachycardia into five groups. It is true there are good reasons for believing in the identity of flutter and paroxysmal tachycardia, but these matters are far outside the range of the average student. Other criticisms of the same kind could be cited.

The author has brought together here many themes that have interested him, and the whole work makes stimulating reading for the physician or cardiologist who can weigh the statements against his own experience. But the student who has no such background will not so readily profit from this approach. No work so individual as this could be free from shortcomings, and the merits of the book far outweigh the demerits. The production is well above the average post-war standard, and the diagrams, electrocardiographs, drawings, and photographic reproductions are on the whole excellent.

K. SHIRLEY SMITH.

AETIOLOGY OF HYPERTENSION

Arterial Hypertension. By David Ayman, M.D. Reprinted from Oxford Loose-Leaf Medicine. Oxford Medical Publications. (Pp. 91. 12s. 6d.) New York and London: Oxford University Press (Geoffrey Cumberlege).

Dr. Ayman is well known for his clinical studies of hypertension, and especially for his researches into the onset and early stages of essential hypertension in the children of hypertensive parents. He takes the view (which would be shared by many authorities in this country) that there is as yet no evidence that essential hypertension in man is initially caused by any disturbance of the renal circulation. In all probability essential hypertension is a functional condition in its early stages. Persons who have inherited the tendency react to physical and emotional stimuli by large and rapid changes in their blood pressure. Organic changes in the cardiovascular system occur later, and are the result and not the cause of the high blood pressure. The author rightly stresses the degree to which these patients are under the influence of their emotions, and the fact that in the early stages the majority of their symptoms are psychogenic, frequently induced by the finding of a high blood pressure at a medical examination. The reader's instinctive approval of this sane outlook on the early hypertensive case receives a rude shock when he finds that Dr. Ayman advises his patients to take their own blood pressures frequently at home.

The great variability of blood pressures in benign essential hypertension is pointed out, and it is clearly shown that most of the claims for one treatment or another are based on cases which have been inadequately controlled. Any placebo, if prescribed with sufficient assurance, will cause significant improvement in the great majority of cases. Only two forms of therapy are known to produce a persistent lowering of blood

pressure: thiocyanate treatment, which requires careful control and which is not free from untoward effects; and sympathectomy, the results of which are still difficult to assess because most surgeons, including Smithwick, have not observed their cases long enough before operation.

Most experienced physicians will agree with Dr. Ayman's general outlook on hypertension. The book has, however, certain rather important shortcomings. The section on pathology is inadequate and of doubtful accuracy. The reader is not given a clear account of the distinctions between essential and secondary hypertension. The description of the malignant phase of hypertension is poor, and nowhere is it made plain that while renal failure practically never occurs in benign hypertension it is almost inevitable in the malignant phase. Finally, the author, like many of his American colleagues, appears to be wholly ignorant of the British literature on his subject; the only British authors to which he refers are Bright, Mahomed, and Allbutt. Although it is natural that an author should refer to the most easily available literature when he is quoting general opinion or the records of cases, it is a serious defect to be completely unaware of important and fundamental observations which have been made in other countries.

ROBERT PLATT.

MENTAL HEALTH

Mental Health. By John H. Ewen, F.R.C.P.Ed., D.P.M. With a chapter by C. Friedman, M.D.(Vienna), L.R.C.P.&S.Ed. (Pp. 270. 12s. 6d.) London: Edward Arnold.

The author sets out to write a short and practical handbook for students and practitioners, and especially for those studying for the Diploma of Mental Health. Like many handbooks, it has fallen between two stools. It is brief, clear, and well set out, with a few short illustrative cases, but it is on strictly conventional lines without any originality or fresh ideas. As such, it is doubtful if it is full enough to allow the specialist student to appreciate the various theories and experimental work on which modern psychiatry is based. For the undergraduate, who is in most cases going to be a general practitioner, the situation is different. Surely the time has now come when in psychiatry, as in everything else, the emphasis in textbooks should be changed so that the student may learn what will chiefly concern him in day-to-day practice. Certainly the practitioner should have some idea of the symptoms and prognosis of the major psychoses, but the conditions he will be faced with are the psychoneuroses, the psychosomatic diseases, and the minor deviations from the strict norm which are not really diseases at all. As in so many textbooks of psychiatry, the psychoneuroses get short shrift in only 24 pages, and practically no mention is made of their treatment except in the section on special treatments—well set out by Dr. Friedman—where narco-analysis is described, but this is not common therapy for the general practitioner. Admittedly, it would not be easy to write a really effective textbook for the general practitioner, but do we need yet another conventional handbook of psychiatry, however good it may be?

R. G. GORDON.

In the preface of his *Introduction to Medical Psychology* (pp. 171; 17s. 6d.; London: William Heinemann Medical Books, 1948) Dr. Erwin Wexberg remarks the absence of suitable textbooks on psychology for preclinical medical students. He has set out to write one, and has certainly produced an interesting and informative handbook. Nevertheless, for British students the book makes the wrong approach to the subject. The first chapter discusses from the philosophical aspect the relations of the individual with the community, and it is doubtful if the preclinical student has sufficient preliminary education to grasp a dissertation on values. The acquisition of knowledge is dealt with chiefly from the *Gestalt* viewpoint, but though this is a physiological approach it is not a very easy concept to follow. In describing the emotional side the author refers frequently to Freudian theory and terminology, which is not suitable for the undergraduate, and certainly not for the preclinical student. It would be better to teach preliminary psychology on a basis of physiology, examining the complex relationships of the individual to his fellows at the end rather than the beginning of the course, and so far as possible leaving the psycho-analytical theory until the clinical aspects of mental illness are reached. If the other approach is favoured, however, this book has the merits of brevity and clarity.

BOOKS RECEIVED

[*Review is not precluded by notice here of books recently received*]

Functional Localization in the Frontal Lobes and Cerebellum. By J. F. Fulton, O.B.E., M.D., D.Sc., LL.D.Birm. (Pp. 140. 15s.) Oxford: The Clarendon Press. 1949

Diagnosis of Viral and Rickettsial Infections. By F. L. Horsfall, jun., M.D. (Pp. 153. 21s.) London: Geoffrey Cumberlege. 1949.

Interne Praxis. By H. Dopsch and E. Kurtisch. (Pp. 741. 60s.) Vienna: Verlag Wilhelm Maudrich. 1949.

Serologische Reaktionen und Immunität bei Malaria. By H. Hormann. (Pp. 106. M. 7.50.) Stuttgart: Hippokrates-Verlag Marquardt. 1949.

Die Individuelle Reaktionsweise bei Chirurgischen Infektionsprozessen. By G. Hegemann (Pp. 126 M. 12.) Berlin: Springer. 1949.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 13 1949

THE ADRENAL GLAND

It is one hundred years since Thomas Addison first described, at a meeting of the South London Medical Society, the disease which bears his name, and in the opening pages of this issue of the *Journal* Sir Henry Dale pays tribute to his pioneer work on the adrenal gland. Addison's vivid description of the clinical changes occurring in many parts of the body as a result of destructive disease of the suprarenal capsules suggested for the first time the importance of the control exercised by these glands over many body tissues. But although Addison's clinical observations on the disease were so exhaustive and novel they came at a time when neither physiology nor biochemistry was sufficiently advanced to carry much further the work he had begun. The study of other glands was for many decades to prove more fruitful to the investigator, and Sir Henry Dale traces the way in which the secrets of these other glands were to be disclosed one after another. The clinical results of over- and under-function of the thyroid gland were recognized. Its hormone was readily obtained in active form and many years later was brilliantly synthesized by Harrington and Barger. The internal secretion of the pancreas was obtained by Banting and Best, with consequent changes in the conception of diabetes and of its treatment. The clinical disturbances of the pituitary were classified, and many of the secretions of this gland were identified and put to clinical use. But during all this time it was clear that the main activities of the adrenal gland, on which the maintenance of life depends, had eluded understanding. Adrenaline, the hormone of the adrenal medulla, had been isolated at a relatively early date, its physiology had been thoroughly worked out, and it had been used widely in clinical practice. But study of the action of adrenaline alone went very little way to explain the various disturbances resulting from disease of the adrenal gland.

It was not until 1931, more than 80 years after Addison's description of the disease that bears his name, that Swingle and Pfiffner first succeeded in preparing an active extract of adrenal cortex which could prolong life in the adrenalectomized animal. At about this time a developing partnership between organic chemists and physiologists was beginning to prove very fruitful in the investigation of the sex hormones. Progress was rapid, and the chemical formulae of most of these hormones were worked out. The endocrine secretions of the testis, ovarian follicle, and corpus luteum proved to have in common a chemical structure consisting of four united carbon rings, three of which contain six carbon atoms and the fourth five carbon atoms. The active hormones such as testosterone, oestradiol, and progesterone vary mainly in the number and position of ketone, hydroxyl, methyl, and other groups attached to the carbon atoms of this ring skeleton. Thus the natural oestrogens have one methyl group, the androgens two, and progesterone three. Elsewhere in this issue Professor H. de Watteville and Drs. S. Salinger and R. Borth discuss the clinical value of sex-hormone determinations.

The chemical knowledge acquired in studying the sex hormones has proved useful in the investigation of the nature of the active constituents of Swingle and Pfiffner's adrenal cortical extract. This too was found to contain many compounds having the same four-carbon-ring skeleton as had been found in the sex hormones, the variation again being mainly in the attached groups. A large number of such substances have been isolated from adrenal extracts and from urine, in which they are present in much smaller amounts. Only a few of these compounds have much physiological activity—desoxycorticosterone, with its powerful action on salt and water metabolism, being the best known and most widely used. Another group is characterized by the presence of an oxygen atom on the eleventh carbon atom of the ring skeleton and a reducing group similar to that of fructose on the seventeenth carbon atom. Compounds of this group have little or no action on salt and water metabolism, but have a great influence on carbohydrate metabolism—causing glycogen to be deposited in the liver, increasing body resistance to the action of insulin, and hastening recovery of muscle from fatigue. It is to this group that the now famous "compound E" ("cortisone") belongs, a substance which, although not yet available in this country, has already been the subject of much discussion because of its dramatic effect in certain rheumatic diseases.[1]

Addison's brilliant analysis one hundred years ago led to the development of the now flourishing science of endocrinology, but only now are the many problems connected with the secretions of the adrenal gland beginning to be unravelled. The importance of future discoveries can only be surmised. The effect of cortisone on rheumatoid arthritis is indeed extraordinary, but there are hints that the adrenal cortex has other important actions. Many conditions of "stress" are now known to increase the activity of the cortex, and if the stress is long continued adrenal exhaustion can be induced in

[1] *British Medical Journal*, 1949, 1, 812, and 2, 24 and 221.
[2] *J. clin. Endocrinol.*, 1946, 6, 117.

animals. Selye[2] believes that such exhaustion may lead by adrenal dysfunction to a wide variety of diseases. Injections of desoxycorticosterone in animals have caused such varied conditions as myocarditis, arthritis, nephritis, Aschoff's nodes, and periarteritis nodosa. In man the urinary excretion of the carbohydrate-active adrenal hormones is found to be increased after such stress as pregnancy, surgical operations, burns, and heart failure, and a fall in their excretion has been observed shortly before death. In experimental animals these hormones increase ability to survive low oxygen tensions. This action is especially interesting, for it was a rumour, probably unfounded, that the German Luftwaffe was using cortical extracts to increase the high-flying ability of its pilots which did much to stimulate official interest in the U.S.A. in these hormones during the last war.

There is urgent need for a wide trial of these new and active compounds in therapeutics, but here again the adrenal gland presents its challenge. The amounts of these hormones stored in the gland are small compared with the quantities produced and used by the body daily. Extraction of glands is thus an inefficient method of obtaining them, and it is to be hoped that chemical synthesis will soon be achieved. Desoxycorticosterone has been produced commercially for a number of years, but the comparable production of the allied carbohydrate-controlling compounds presents problems likely to tax the ingenuity of organic chemists for many years to come. Cortisone has been obtained by partial synthesis from a bile acid, but the yield after a long series of chemical processes is less than one-thousandth part of the theoretical. A great expenditure of effort and money soon led to the mass production of penicillin, and it is now certain that a comparable effort will be required if the needed hormones of the adrenal cortex are to be produced in sufficient quantity. There is little doubt that during the next decade or two we shall witness some startling developments in adrenal physiology and that clinical medicine will be greatly influenced by them. The pioneer work of Addison will then be seen to have possessed an even greater significance than has been apparent hitherto.

HISTOPLASMOSIS

If the history of histoplasmosis were to be written in popular instead of what has recently been called clinical journalese it would undoubtedly be described as intriguing. In 1906 Darling[1] in Panama reported the occurrence of a disease characterized by visceral symptoms and the presence of small intracellular bodies in the cytoplasm of mononuclear cells. Since Darling was a protozoologist and the condition had some similarities to leishmaniasis, it was naturally thought to be due to a protozoon. Not until twenty years later was a comparable case reported from the continental United States, and only in 1934 did de Monbreun[2] successfully cultivate the organism from the blood of an infant and by demonstrating the mycelial forms clearly prove that it was a fungus and not a protozoon. Later he was able to inoculate monkeys and mice and to infect puppies by feeding them with the mycelial forms, thus showing that the fungus may enter the body by way of the gastro-intestinal tract. By 1939 only 4 cases had been recorded in the United States, but one year later Meleney[3] managed to collect no fewer than 32.

The fungus responsible for histoplasmosis is known as *Histoplasma capsulatum* and is probably unique, since it is the only fungus pathogenic for man which is primarily an intracellular parasite of the reticulo-endothelial system. In tissue sections or smears the parasites appear as round or oval bodies 1 to 5 μ in cross section with chromatin irregularly distributed at their centre and with colourless refractile capsules. They can be stained with haematoxylin and eosin, though Giemsa's method is preferable. The mycelial forms grow readily on blood-agar or Sabouraud's medium, though from three to four weeks at room temperature may be necessary before growth is visible[4 5]; 50 units of penicillin and 50 units of streptomycin per ml. should be added to the culture medium when attempts are made to isolate the fungus from ulcerating lesions. As would naturally be expected, the organs specially involved are those containing abundant reticulo-endothelial tissue: liver, spleen, lymph nodes, and the lymphoid structures of the pharynx and intestines are not uncommon sites of this somewhat chronic granulomatous condition.[6] Ulcers of the skin, bowel, pharynx, and mouth may constitute the most important lesions. According to Weed and Parkhill[5] the ulcers have rolled edges, and are associated with fever, sweating, and loss of weight. Only cartilage and the cortex of bone invariably escape, as they are devoid of reticulo-endothelial cells. Greyish-white nodules or ulcerations may be seen on the surface of the affected organs. Histologically there is proliferation of the lymphoid tissues with considerable cellular destruction; the causal organisms can be seen within the mononuclear cells. Granulation tissue with macrophages containing

the parasites is present outside the necrotic zone, and in addition there are giant cells, polymorphonuclear leucocytes, eosinophils, lymphocytes, and plasma cells. The parasites are capsulated and basophilic.

The signs and symptoms of histoplasmosis are, as is to be expected, very varied. In general it develops as a systemic febrile disease, associated with loss of weight, anaemia, leucopenia, and enlargement of lymph nodes, liver, and spleen. Gastro-intestinal symptoms, including diarrhoea, have been mentioned in nearly two-thirds of the reported cases; oral lesions, when present, closely resemble those seen in leukaemia. Hodgkin's disease may be suspected at first, and in fact Hodgkin's disease, noma, or carcinoma has been present in 14 out of 70 cases.[7] When the suprarenals are affected Addison's disease may be produced. Pulmonary spread, as shown by *x*-ray examination, is characterized as a rule by multiple small foci, frequently subpleural, but Meleney[3] regards the lungs as more often the sites of secondary infection than the portal of entry of the fungus. It is thus obvious that no typical clinical picture of histoplasmosis exists; it may simulate many systemic diseases, and one case of endocarditis due to *H. capsulatum* has been reported. Possibly it may occur in a subclinical form.

Although histoplasmosis has so far been recorded mainly from the New World, it has been seen in members of various races. The sex incidence is approximately equal, and there is no correlation with any occupation. No less than a quarter of the cases in one series were in children under the age of 13 years. The outcome of clinically recognizable disease has usually been regarded as invariably fatal, the duration having been from one to eight months, though some adults have been infected for a year or more. There is now, however, evidence from Kansas City and elsewhere that non-fatal cases may occur.

Very little is yet known of the epidemiology of histoplasmosis. Though widely distributed in the United States, it is particularly prevalent in the south-eastern area, but at least one case has occurred in California.[8] McLeod and others[9] reported the only instance in which there was contact between proved cases; since the patients were siblings, the disease may have been transmitted either from one to the other or from possibly a common source of infection. Pará[10] described one case where there was possible contact between an infant and a dog with histoplasmosis. Harmon[11] collected 10 cases of the disease in dogs in the United States, and has now added two further cases seen by himself. Emmons and his colleagues,[12] in an area in Virginia where four human and three canine cases of histoplasmosis had occurred, examined the tissues of 1,620 fur-bearing animals, mostly small rodents. *H. capsulatum* was grown from the tissues of one mouse and five rats (*Rattus norvegicus*); in a further note isolation from five other rats is recorded. No gross lesions were seen in the tissues of the infected animals, only small foci. In this connexion it is of interest that white mice and guinea-pigs commonly recover from the acute phase and survive indefinitely, but so does the fungus, since the liver and spleen continue to yield positive cultures. It is thus not improbable that rodents and dogs are the source from which human beings are infected.

The final diagnosis of histoplasmosis can be made only in the laboratory. The parasites may be seen in thick smears within monocytes in the peripheral blood stream. Puncture of the spleen, sternal bone-marrow, or superficial lymph nodes may reveal the organisms, as may biopsy material taken from accessible sites of infection. Inoculation of guinea-pigs with blood, or cultivation of the parasites on suitable media, may provide an answer. A recent method of diagnosis is skin testing with histoplasmin, which is simply a sterile broth filtrate of *H. capsulatum*. It appears, however, that a number of persons who have no previous history of infection with histoplasma give a positive reaction with histoplasmin. Related to this is the finding that in a proportion of these individuals there is evidence of pulmonary calcification and at the same time no reaction to tuberculin. Palmer,[13] for instance, in a survey of 3,105 student nurses found calcification present in 31.1% of those positive to histoplasmin but in only 10.4% of those positive to tuberculin. Some other fungi may be responsible for positive reactions to histoplasmin,[14] and in certain areas in California it is suggested that coccidioidomycosis may be the cause of such calcifications. Furcolow and his colleagues[15] also emphasize that in regions of the United States where histoplasmin sensitivity is widespread not only calcifications in the lungs but also diffuse patchy infiltrations are very frequently non-tuberculous. Various attempts have been made to use complement fixation for diagnosis. Histoplasmin as an antigen has not proved very specific, but Salvin[16] has obtained far better results with the intact formalin-fixed, yeast-like forms of the fungus cultivated on a special medium—an antigen which he terms "Y.P." While the majority of cases of histoplasmosis have been seen in North and Central America, reports are now coming in that the disease exists also in the Philippines.[17] It is probable that the disease is much more common than was originally supposed and probably not nearly as fatal.

Treatment of histoplasmosis during the acute phase has so far proved unsuccessful. Penicillin, the sulphonamides, potassium iodide, arsphenamines, quinquevalent antimonials, and radiation therapy have all proved valueless. Recently Fontaine and his co-workers[18] have found that an antibiotic isolated from young tomato plants and

at first called lycopersicin, but now tomatin, has an inhibitory action on the growth of cultures of *H. capsulatum*. Since tomatin has a low toxicity in animals, a description of its action on this fungus infection *in vivo* would be of considerable interest.

CARCINOMA OF THE GALL-BLADDER

The prognosis in cases of carcinoma of the gall-bladder is gloomy, and inevitably surgeons have sought means of preventing this condition. There can be little doubt that cholelithiasis is a predisposing factor of the greatest importance, and a number of authors report the presence of stones in from 70 to 100% of cases of carcinoma of the gall-bladder.[1-4] This variety of malignant disease is not so uncommon as is generally believed; Kirschbaum[2] places the incidence at 3% of all carcinomata, while Graham[1] gives a higher figure of 8–10%. A further point of interest is that carcinoma of the gall-bladder is found at operation in some 1–5% of cases of cholelithiasis, and the former condition has generally never been suspected.

With the above considerations in mind Sainburg and Garlock[5] have reviewed 75 cases of carcinoma of the gall-bladder. Abdominal pain, a history strongly suggestive of gall-bladder disease, loss of weight, and jaundice were the most important features of these cases, but the authors stress that at this stage the disease is generally advanced and incurable. Only 65 of their patients were subjected to operation. The group in which the best results were obtained consisted of seven cases in which the diagnosis was made by the pathologist and was not suspected by the surgeon: one patient in this group was still alive after 13½ years, but the average period of survival of the others was less than one year. In the remaining cases the average period of survival varied between 2–3 months in the frankly inoperable group and 6–7 months in those cases where it was believed that complete excision had been done. From these figures it can be seen that surgery is virtually useless when the disease is established, though an occasional very early case may survive. As the incidence of carcinoma in gall-bladders containing stones is far from negligible—Kirschbaum mentions a figure of 3% and Graham one of 5–14%—and as the overall mortality of cholecystectomy is unlikely to exceed 3% there would seem to be a strong case for "prophylactic" cholecystectomy in all cases of cholelithiasis.

As a result of a 10–20-year follow-up of 112 cases of silent gall-stone, Comfort and his colleagues[6] at the Mayo Clinic adopt a somewhat different attitude to the problem of gall-stones. Sixty-one patients had no symptoms during the ensuing years, while 24 of the 51 patients developing symptoms had had a cholecystectomy. There was no record of cancer of the gall-bladder in any of the 28 patients who had died, but it should be noted that this follow-up was undertaken by post and the information obtained was incomplete. At first glance these findings may appear to be completely at variance with those of Sainburg and Garlock, but the risk of carcinoma i perhaps less in those cases of gall-stones without symp toms. It might be reasonable to suggest, therefore, firs that all cases of cholelithiasis with symptoms should b treated surgically unless there is some definite contra indication to operation; secondly, that cases of silent gall stones in fit and young patients should also be treate surgically, for, although the work of Comfort may sugge the relative immunity of such cases from carcinoma, ther is no means of telling how long the stones will remai silent; and, finally, that in elderly patients with silent gal stones a conservative attitude might be adopted, since th risk of malignant change in their few remaining years ma well be less than the risk of operation. The evidence i favour of gall-stones being the most important predisposin factor in carcinoma of the gall-bladder is overwhelmin and it is clear that the removal of gall-stones is th surgeon's most effective method of preventing carcinom of the gall-bladder.

ANIMAL INFECTIONS AND PUBLIC HEALTH

Delegates from 53 countries have been attending discussion on animal health and disease control during the fourteent International Veterinary Congress in London, whic met this week. The theme of the Congress was th world food situation—"the most important scientif and practical question of the day"—and Lord Boy Orr was the principal speaker at the opening discussio The fact that no less than eight papers were read o public health subjects is a reminder that medical men an veterinarians have many interests in common. It has course long been recognized that comparative patholo affords a meeting-place for medical and veterinary scienc but the need for co-operation between medical pract tioners and veterinary surgeons has only recently receiv much attention. It might be thought that the limitatio in value of animal, as opposed to human, life would restri the use of laboratory services for diagnosis in veterina medicine. To a certain extent this is true, but an increasi number of veterinary surgeons regularly use a microsco in their work, and the veterinary pathologist is never sho of material.

The first human infection with *Leptospira canico* in this country was reported three years ago,[1] and a recent paper McIntyre and Stuart[2] stated that t medical profession "might be helped here by veterinaria who were actually diagnosing the disease in dogs and in cating to the owners the risk run by human contact They described one case where diagnosis of infection a dog had led to its discovery in the owner. The sa observations apply also to tuberculosis, which is not u commonly found in the dog—more often affecting t abdomen than the chest. Tubercle bacilli are frequen present in the nasal discharge of cats brought for veterina attention because of "catarrh." The cat, unlike the d has a relatively high degree of resistance to the hum bacillus, but is more susceptible to the bovine. Wheth the disease happens to have been transmitted from t animal to the owner or vice versa, the veterinary surge

makes a contribution to public health when he diagnoses the disease and advises the destruction of the animal. Here again the medical practitioner may sometimes be glad to be acquainted with the veterinary findings. Brucellosis,[3] salmonella infections, louping-ill,[4] anthrax, and erysipelas are seen in both medical and veterinary practice, and the apparent increased incidence[5] in this country of the beef tapeworm—*Taenia saginata*—is of common concern to doctors and veterinarians.

THE NUFFIELD FOUNDATION

In its first year of activity—1943—the Nuffield Foundation laid plans for the future, and the next five years were devoted to grant-giving. During this period grants of considerably over £2,000,000 have been distributed, of which nearly £600,000 has been allocated to the medical sciences. The major grants have included an endowment with £100,000 of the Nuffield Chair of Child Health, which was the Foundation's contribution to the creation of the Institute of Child Health in the University of London; grants of £70,000 to Manchester University and of £40,000 each to the Universities of Durham and Glasgow for the development of departments of industrial health; grants of £90,000 to four university schools for dental research and teaching; and a grant of £100,000 over 10 years from 1947 to the University of Manchester for research in chronic rheumatism. The fourth report[1] of the trustees is interesting not only as a record of past achievement but as a statement of future policy. The aim which has guided the trustees in their choice of projects in the medical sciences has been to promote the proper understanding, definition, and maintenance of health rather than, as a rule, to seek cures for established diseases; the research on rheumatism is and will remain for the present the principal exception.

The grants just quoted may seem large, but they are not large in comparison with State expenditure on research. In the Civil Estimates for 1949–50 a total of over £100,000,000 is shown for Government expenditure on research and development and on the universities. Elsewhere in this issue the work of the Colonial Research Council is reviewed, and here the annual allocation of grants runs into seven figures. With the State so large a paymaster, private patrons, however great their resources, might well be discouraged. Yet private benefactions, which are not subject to State audit, have the vital function of ensuring that the "creative minorities," to which Mr. Arnold Toynbee in his *Study of History* attributes the genesis of civilized progress, get at least a first hearing and the chance of commanding wider support. Moreover, the comparative smallness of privately provided funds imposes a more critical selection of projects for support. The Nuffield Foundation sets itself to try out the unique person or project, but, as a rule, supports that person or project only through the medium of an established institution, so that if the value of the venture is proved the work can be continued after the Foundation's necessarily limited support has had to cease.

With this as its general policy the Foundation intends during the next five years to devote more attention to biological and social studies. These have been, if not the Cinderellas of research, rather poor relations in the family. They do not offer the excitement to be found in research in physics. The investigator is apt to feel that nothing very remarkable remains to be elucidated and that his work is mainly a question of classifying what is already vaguely known. In the field of biological studies the normal mechanism of growth, differentiation, and self-maintenance of living things will have attention, and in the social sciences an attempt will be made to bring such subjects as social anthropology and sociology up to the level of the more highly developed science of economics. In addition the Foundation will encourage greater co-ordination of research. Hitherto this has been to a large extent individualistic. The experts in various subjects should be brought together, and they should work out their problems by joint effort. The great work of the Foundation on behalf of old people will be continued, and so will the system of medical and other fellowships.

DENTAL CARIES

In 1885 Miller[1] drew attention to the fact that acid-producing organisms were common inhabitants of the mouth, and that if they were incubated with sugars they produced acids capable of dissolving the enamel covering a tooth. This led to what became a generally accepted hypothesis about the cause of dental decay, which, briefly stated, is that food debris such as carbohydrates, if allowed to stagnate in the mouth, is broken down by bacteria with an organic acid as an end product. This acid acts directly on the calcium phosphate which forms the bulk of the enamel, producing a soluble calcium salt. Many attempts have been made without success to reproduce the carious process *in vitro*, for although the enamel can be disintegrated in this way the appearance bears no resemblance to that of caries when produced in the mouth. The theory, however, seems to be supported by the fact that caries commonly starts in a tooth in sites where food stagnates, and, conversely, very rarely occurs on a surface that is kept clean and free from food and debris by the action of the tongue or lips. A diet containing an excess of carbohydrates, particularly if its consistency is such that it adheres to the teeth, also predisposes to rapid caries.

On theoretical grounds the fact that chemical analysis shows that inorganic salts compose about 99% of enamel, calculated by weight, suggested that the organic compound was too small to be of importance. The destruction of enamel, therefore, would appear to be a process of decalcification. No satisfactory explanation has, however, been put forward to explain why acids formed on the surface of a tooth should combine with the fixed calcium of the enamel rather than with the more freely available calcium ions in the saliva, and little account has been taken of the buffering properties of the saliva. Latterly, more attention has been paid to the organic component of the

[4] *Brit. dent. J.*, 1937, 63, 511.

enamel, and it is now recognized that, although it forms an apparently insignificant part when assessed by weight, when account is taken of the different density it is found that by volume it forms about 5% of the enamel. Until recently histological investigation has been limited to the examination of hard-ground sections, because the organic matrix is also freely soluble in acids and was lost when attempts were made to prepare a decalcified section by ordinary methods. But Frisbie[2] at San Francisco and Sognnaes[3] at Harvard have now overcome this difficulty and, using special methods of fixation, have demonstrated that the organic matrix of the enamel can be preserved in decalcified sections. Frisbie and his co-workers have thus been able to produce convincing histological evidence that the initial stage in enamel caries is the result of a bacterial attack on the organic matrix, but so far they have not succeeded in isolating any mouth organism that will attack enamel *in vitro*.

In 1937 Dr. P. Pincus[4] demonstrated that certain proteolytic bacteria could bring about the disintegration of enamel in a media that remained above *p*H 7 and contained no carbohydrate. They presumably did this by breaking down the organic matrix. In this issue of the *Journal* he describes more recent work which suggests a double action. He considers the enamel matrix to be a mucoprotein containing mucoitin sulphuric acid, and he claims to have isolated from the mouth an organism that produces an enzyme, sulphatase, that can break down a mucoprotein and at the same time liberate sulphuric acid ; the latter combines with the calcium phosphate and forms a more soluble salt. That caries is, in fact, the result of such a process awaits further proof. So far no one has succeeded in isolating an organism from a carious lesion that will attack the organic matrix of intact enamel. The problem would now appear to rest with the bacteriologist. A solution is urgently required, for until it is found it is impossible to plan the prevention of caries in a rational way.

PENICILLIN IN PSITTACOSIS

The first indication that penicillin had a therapeutic action in any virus disease was the work of Heilman and Herrell[1] on the treatment of experimental ornithosis in mice. Using a strain of virus derived from a pigeon, they were able by penicillin treatment to reduce the mortality from 87.5% to 5% when inoculation of the virus was intraperitoneal, although the disease produced by intracerebral inoculation was little affected, presumably because of the inability of penicillin to pass the blood-brain barrier. Since then there has been further experimental evidence that penicillin has an action on this virus, and there have also been clinical reports of the penicillin treatment of human psittacosis. These are reviewed in this issue on p. 362 by Dr. J. R. Tasker, who adds a report of a further case of peculiar significance. The circumstances of its occurrence enabled the diagnosis to be made at an exceptionally early stage, and the attack was evidently a severe one. The large doses of penicillin which have been calculated on the basis of animal experiments to be necessary for controlling this infection were given from the first, and the rapid abatement of fever and the general clinical improvement which followed can have been due only to the treatment.

This comparatively rare form of virus pneumonia is the only one for which penicillin is of any value—in primary atypical pneumonia it is without effect. For the treatment of this and perhaps certain other virus diseases the drug of choice is "aureomycin"—the new antibiotic which has so astonishingly enlarged the effective range of chemotherapy. The successes achieved by this drug have in part falsified the general belief in the insusceptibility of viruses as a whole to the action of antibiotics. On the other hand, it should not be supposed that there is any immediate prospect of effective chemotherapy for the majority of virus diseases: among those on which no known drug has any effect are poliomyelitis, influenza, and the common cold.

CHEMOTHERAPY OF LEUKAEMIA

Many drugs have been used in the treatment of leukaemia, but, since palliative effects only have been obtained, assessment of their value is very difficult. Arsenic and benzene had the disadvantage that when given in adequate doses they often caused toxic reactions. In cases of chronic leukaemia prolonged remissions have been reported after treatment with urethane[1] and nitrogen mustards,[2] though no permanent cure has been obtained with any of these compounds. Until publication of the work of Farber and his colleagues[3] acute leukaemia was thought to be uninfluenced by drug therapy. These American workers, however, found that the extremely potent anti-folic-acid agent 4-aminopteroylglutamic acid or "aminopterin" caused remissions in children suffering from acute leukaemia. Although aminopterin is most effective in children there was an indication that it might sometimes be beneficial in cases of acute leukaemia in adults. Aminopterin has been used in this country during the past year, and temporary remissions in the course of acute leukaemia in children have been obtained. The drug is very toxic, and for this reason treatment cannot usually be continued for any length of time. A new folic acid analogue, 4-amino-N^{10}-methylpteroylglutamic acid, appears to be more effective than aminopterin in the treatment of leukaemia in mice.[4] A few cases of monocytic anaemia in adults have been treated with aminopterin ; its action in bringing about temporary remissions is remarkable. One such case is described in this issue of the *Journal* by Dr. P. L. de V. Hart, and other case reports are being prepared for publication. These results are important, for they should lead to a better understanding of the nature of leukaemia and also, perhaps, to effective chemotherapy of the disease.

Lord Horder has been appointed an Extra Physician, Sir James Walton an Extra Surgeon, and Sir Morton Smart an Extra Manipulative Surgeon to His Majesty's Medical Household.

THE WORLD HEALTH ORGANIZATION AND TUBERCULOSIS*

BY

J. B. McDOUGALL, C.B.E., M.D., F.R.C.P.Ed., F.R.S.Ed.

Chief of Tuberculosis Section of WHO

From the earliest meetings of the World Health Organization tuberculosis was regarded as one of the subjects to be given the highest priority in its deliberations. An international committee was set up by the World Health Assembly to lay down certain principles as a general guide for future action. In the first report of the committee, which was accepted by the World Health Assembly in 1948, a number of techniques recommended for adoption were set out briefly. I propose to enumerate the most important of these and to refer to the action which has so far been taken to implement them.

It is necessary first to determine the extent of the problem of tuberculosis in each country, the facilities at its disposal, the manner in which they are being used to tackle the problem, and the additional facilities required. Officers from the tuberculosis section of WHO have already visited Poland, Belgium, Hungary, Switzerland, Greece, and Ethiopia and have studied all aspects of the tuberculosis problem. Other officers are conducting similar surveys in South-East Asia, the Eastern Mediterranean, and Central and South America. A schedule has been prepared which ensures that the information obtained from each country is as uniform as possible. In this way it is hoped that comparable facts will soon be available from a very large number of countries.

A second important problem is recruitment and training. In most countries there are not enough trained workers in the tuberculosis field. Travelling fellowships in four special fields —administration, epidemiology, laboratory work, and clinical work—are being awarded to the countries most in need. For the present year the number of fellowships in tuberculosis alone is limited to 34, but in 1950 it is hoped that at least 50 will be available. The policy here is to select the more senior officers who are already in key positions in their Government's service and who can be spared for periods of from four to six months to obtain a wider view of the work they are normally called upon to do.

Next, it is felt that the best way to get a new programme started or to improve a poor one is by means of field services in one of the special fields of tuberculosis control. Well-trained teams even with limited supplies and equipment can demonstrate what should be done and how to do it. The size of the team and the length of its stay vary, but the object is to keep the team small and to limit the period of stay to a minimum. These teams take their own supplies and equipment, and it is an essential condition that the country shall agree beforehand to take over the project as soon as sufficient of its own personnel have been trained.

Thus in China a small team has trained local doctors in the miniature film method for mass surveys. Seven centres have been established in the country at Shanghai, Peking, Tientsin, Nanking, Mingpo, Hangchow, and Canton, and the entire tuberculosis dispensary organization has been overhauled. The techniques of tuberculin-testing and B.C.G. vaccination have also been demonstrated, and some 70,000 cases have been examined during the past year. Assistance has been given in the formation of a new national tuberculosis association. In addition WHO arranged with the authorities for 12 Chinese doctors to visit Europe and the United States during 1947 and 1948. Those doctors have now returned to their native country to continue the work started by WHO.

In Poland, the Government has been advised on the establishment of a model tuberculosis scheme for the province of Lodz, and during 1948 one of our x-ray technicians was working constantly in the country, erecting and often repairing apparatus which had been given by Unrra. The same technician trained over 100 students in elementary technical work, and as a result apparatus which was previously of no value to the country is now functioning well.

In Greece, the efforts of the Unrra team which was in the country in 1945–6 were continued through 1947 and 1948, though on a smaller scale. Even so, some 300,000 people have been x-rayed and, after careful checking, a morbidity rate of nearly 3% of clinically significant cases has been established as common to most urban communities. A new chest hospital has been set up, and it is fair to say that in Athens especially progress in diagnosis and treatment has gone on apace. Unfortunately, however, work in the provinces has suffered owing to the civil war.

Another WHO team visited Madras in the summer of 1948 with the object of establishing a B.C.G. laboratory which would serve South-East Asia. Between May and December, 1948, the laboratory was equipped, and vaccine of the required potency was available at the end of the year.

International Children's Emergency Fund

Perhaps the most important work undertaken has been in association with the International Children's Emergency Fund, which has as its special responsibility the B.C.G. vaccination campaign in many parts of the world. WHO takes no direct part in the field work of this activity but confines itself to giving technical assistance and advice on the research aspects of this project.

Already in Europe some 8,000,000 persons have been tuberculin-tested and 3,000,000 vaccinated, and at this moment a campaign is extending into India, Ceylon, Morocco, Algiers, and Tunisia. Shortly it will be further extended in China, and requests for assistance have also come from Mexico, Ecuador, and Bolivia. A research group is trying to obtain more precise data on details of technique and results, and to evaluate the B.C.G. vaccination programme in the prevention of tuberculosis morbidity and mortality. Some indication of the importance which the executive board of WHO attaches to this research is reflected in the proposed estimate for 1950, when a sum of approximately £75,000 will be available for this work.

Perhaps one of the most difficult and yet most valuable functions of WHO is that which aims at developing and recommending uniform procedures, whether it be in tuberculin testing, classification, laboratory diagnosis, or in the evaluation of new chemotherapeutic agents such as streptomycin. Already a streptomycin subcommittee has met in New York and has published its recommendations. The International Children's Fund has given supplies of streptomycin to some countries in Europe, and a WHO expert is supervising the clinical trials and endeavouring to get some uniformity in the documentation of cases. So far as the classification of tuberculosis is concerned WHO has requested all member Governments to express their opinion on the simplified classification by the four-digit code method which has already found favour in Denmark and the U.S.A.

This brief review of the initial work of WHO would be incomplete if I did not refer to the great desire which the organization has to work in the closest possible harmony with the International Union against Tuberculosis. WHO is essentially an inter-governmental agency and makes no direct contact with national organizations. The policy is to contact national voluntary organizations only through the accredited international agency. In view of the vast amount of work which has been done, and is still being undertaken, by voluntary agencies in many parts of the world, it seems imperative that there should be an efficient and powerful international voluntary agency to collaborate with the innumerable voluntary and private agencies in many parts of the world which are interested in stemming the death rate from this disease. The recent suggestion therefore that the present International Union should be reorganized to assume its rightful responsibility in this work is welcomed by WHO, and the fact that the present director-general of the Union, Professor Etienne Bernard, is also a member of the Expert Committee of WHO on tuberculosis

*Summary of an address given to the British Tuberculosis Association at Cambridge on April 6.

does something to ensure that there will be a close co-operation between the two organizations.

The international approach to tuberculosis control is one which I believe must be encouraged. Not only is this missionary work welcome, but I do not hesitate to say that those who go into the back lanes and alleys of the globe learn more about tuberculosis epidemiology than they had ever known. It is the very magnitude of the task which attracts.

The function of an international organization in countries with undeveloped programmes must be to guide and direct, not with a view to the duplication of the schemes which may be successful in Western Europe or North America, but only in directions in which we feel sure these countries will be able to follow within the limitations of their own economy and available personnel. International assistance must never be substituted for national effort, for in the long run the destiny of any country's programme must be established by its own workers, and in no sphere does this apply more than in tuberculosis, with its numerout social and economic ramifications, which are best known only to those who are intimately familiar with local conditions.

STABILITY OF THE NATION'S HEALTH

ANNUAL REPORT OF THE MINISTRY

In the report of the Ministry of Health just issued for the year ending March 31, 1948,[1] the comments of the Chief Medical Officer, Sir Wilson Jameson, and his staff relate only to 1947, a year of exceptional trial for the British people. During the first three months the country was visited by one of the severest winters on record, and fuel restrictions were added to scarcity of food. This was followed by the heaviest floods for half a century, which denuded the sheepfolds and threatened the harvest. Then came a period of economic crisis and dollar deficiency. Bread and potatoes were rationed, the meat allocation was reduced, the bacon ration halved, and other foodstuffs increased in price.

It is a tribute to the resilience of the people that the nation's health, which had been good during the war, also withstood the rigours of the second full year of peace. The death rate rose slightly, chiefly owing to increased mortality in the diseases of old age and the severity of the winter. But infant mortality fell to its lowest figure, notwithstanding the highest birth rate for a generation, and there were further falls in maternal mortality and in the stillbirth and neonatal death rates. There was no abnormal rise in the number of sick people, though the average number of days of incapacity of those who became ill increased. The frequency of colds and respiratory disorders in the January–March quarter of 1947 was not greater than in the previous year, except among old people.

The Epidemiological Picture

Deaths from diphtheria were barely half those of the year before as the result of the intensive campaign which brought 450,000 children to be immunized. Scarlet fever showed a new low record both for infections and deaths. Cases of measles were numerous, but the fatality rate, already exceptionally low, fell once more. The deaths ascribed to influenza were fewer than in any year (save one) since the middle of the first world war. Cases of typhoid and paratyphoid fever were fewer than in 1946, although two considerable paratyphoid outbreaks occurred, one in Bedfordshire and the other in Cambridgeshire. There was a new fall in reported cases of syphilis and gonorrhoea, suggesting that the wartime tide of venereal infection might now have turned. Another wartime manifestation, epidemic hepatitis, declined almost to vanishing-point. Cases of dysentery were reduced by 50%. It had been expected that the resettlement in this country of large numbers of people who had served abroad in malarious areas would lead to a sharp rise in the number of cases of indigenous malaria, but only five notifications were received.

The figures for whooping-cough remained high—over 90,000 notifications and 900 deaths, almost exactly a repetition of the year before. Vaccination against whooping-cough has not yet reached the status of immunization against diphtheria. In 1947 there were more cases of smallpox than in any year since 1934. An unsatisfactory feature was that 6 of the 78 cases were in persons who should have been protected by recent vaccination—a doctor, a sanitary inspector, a nurse and kitchen maid in a hospital, a medical student; and a man working on a disinfection plant. Three of them had received vaccination in infancy, but the others had not been vaccinated at all.

Poliomyelitis

A feature of 1947 was the outbreak of acute poliomyelitis, which reached the unprecedented incidence of 18 per 100,000—four and a half times that of the highest epidemic previously recorded (1938). Fortunately the case fatality of 9.1% was the lowest on record. During the years 1913 to 1946 the case fatality varied between 20 and 30%, except in 1918, when 100% case fatality was recorded. This was probably due to some confusion with deaths from influenza and encephalitis lethargica in that year of great epidemics.

The report gives an account of the measures taken to limit the outbreak. No disease, as Sir Wilson Jameson says, presents more numerous or difficult problems, or causes more family or communal distress. The change in age distribution is noted. Roughly about one-third of the cases were under five, one-third between five and fifteen, and one-third over fifteen, and it was among those over fifteen that two-thirds of the deaths occurred. In 1938 less than a quarter of the cases were over fifteen. The point of constancy about poliomyelitis is its seasonal behaviour—its summer rise and its decline with the fall of the year—but in 1947 the summer rise started before May was out and the peak was reached in early September.

Cancer and Tuberculosis

Deaths from cancer have recently advanced by something like 2,000 a year. It is now an understatement to say, as a lecturer in a cancer campaign some years ago told his audience, "One in every seven of you will die of cancer." The digestive organs and peritoneum are in both sexes the principal sites of attack. There are about as many cases involving those sites as all the other cases put together. Preparations were being made during the year to merge the work under the repealed Cancer Act with that of the forthcoming National Health Service, and a warning is given that with each Regional Hospital Board having its own cancer advisers the existing useful degree of centralization might be lost.

An increase of 4% was shown in deaths from respiratory tuberculosis. This was related to the first quarter of the year, when climatic conditions were exceptionally bad. The number of newly diagnosed cases showed an increase, explained in part by the activity and awareness of general practitioners and tuberculosis officers. Some particulars are given of the mass miniature radiography units. The number operating in England and Wales in 1947 was 23, and up to the end of that year just over two million persons had been examined. Of these more than 94% were found to have no abnormal chest condition.

The National Health Service

Many pages of the report describe the preparations for the National Health Service that was introduced the following year. But this is now ancient history. National Health Insurance saw its last year in 1947, and the service closed with a clean slate. During the year there were only six cases in which money was withheld from practitioners for breach of the terms of service, and the total sum kept back was only £130. No representations were made that the continuance of a practitioner on the medical list would be prejudicial to the Service. Although the figures are now overshadowed by those of the National Health Service, they did relate to twenty million insured persons and to the issue of 67 million prescriptions. The average cost of the prescriptions was 1s. 1¼d.

[1] *Report of the Ministry of Health for the Year ended March 31, 1948, including the Report of the Chief Medical Officer on the State of the Public Health for the Year ended December 31, 1947.* Cmd. No. 7734. H.M. Stationery Office. 1949. 5s. net.

The amount of short-term sickness which was not reflected in the vital statistics and notifications is the subject of a note from the Government Actuary's department. A sharp rise in the level of short-term sickness during the war became general in 1942, perhaps owing to war fatigue, and was maintained until the middle of 1945. Since the end of the war there has been a gradual downward trend. The social survey, in which representative samples of the population are visited in their homes, tells the same story. Medical consultations, excluding those concerned with patients in hospital, averaged 4.5 per person between the ages of 16 and 64 during the whole year, and 7.1 per person aged 65 and over. The average proportion of people over 65 who said that they had been free from illness or injury during the three months preceding the interview was 27%.

The nutritional state of the people remained satisfactory. Although there was rationing of bread and potatoes the allowance was generous. Special attention was paid by the school medical service to the nutrition of adolescents, and in various surveys from 93 to 96% of this section of the population were found to be in good nutritional condition. In 17 areas there was a slight but definite decline in weight in children in 1947 as compared with 1945. The rations and allowances of the school child were still sufficient for his needs, and the number of children taking school meals and milk had increased.

Mental Health and Other Services

For the first time the report includes a chapter on mental health, a subject formerly discussed in the annual reports of the Board of Control. There is still considerable overcrowding in public mental hospitals, in comparison with recognized standards. The overcrowding is serious enough in itself, but it has been kept within limits partly because many mental hospitals have decided to limit admissions to certified cases and have declined to receive voluntary patients. This is detrimental to the whole system of voluntary treatment and involves great hardship to people in the early stages of their illness. Nevertheless, the proportion of voluntary admissions continues to increase, and in 1947 more than half the total admissions were voluntary.

The report contains an immense amount of information on other subjects. It tells the story of the National Blood Transfusion Service, under which, in 1947, 235,492 ½-pint bottles of blood and 64,407 bottles of dried plasma were distributed. There is a chapter on hospital planning, though the Ministry does not commit itself deeply on the question of standards. It is pointed out that standards discourage experiment, and that it is impossible to foresee the conditions that will prevail when building can be freely undertaken.

The work of the Public Health Laboratory Service is described. This service was greatly expanded during 1947. A point of importance mentioned in this section is the increased number of food-poisoning outbreaks, which reached 765 in 1947. Most of these outbreaks were due to salmonella infections, and attention is drawn to the part which imported spray-dried egg may have played in their propagation. But it is clear that in many cases of food poisoning it is the human element that introduces bacteria into the offending food. The two precautions enjoined are that those who handle food should observe scrupulous cleanliness, and that food should be eaten as soon as possible after preparation. Reheating of food, which often takes place in canteens with the left-over dishes, does not destroy staphylococcal enterotoxin.

Dr. Melville Mackenzie gives an account of the work of the interim commission of the World Health Organization and its eleven expert committees. Dame Katharine Watt describes the efforts to overcome the shortage of nurses. Dr. Stock reviews the problems that confront port health authorities. The Ministry's activities in connexion with housing are discussed in another section. Despite the difficulties of the national economic situation a quarter of a million families were provided with new homes during the year. A sidelight is thrown on the Ministry's public relations department when it is mentioned that telephone inquiries by journalists during the year numbered 10,000.

This is probably the most comprehensive document ever issued from the department. It deals with the end of an era, and the next report will describe new incursions by the State in the field of health and medicine. Perhaps it is appropriate to close this review with Sir Wilson Jameson's tribute to voluntary services: "This country has always been fortunate in having at its disposal the help of experienced voluntary organizations and of an army of able and enthusiastic voluntary workers. Never was voluntary service more welcome than it is now, and I would make special acknowledgment of the great assistance the medical side of the Ministry has received from such sources during my term of office."

ALCOHOLISM IN SWITZERLAND

KELYNACK MEMORIAL LECTURE

Dr. HENRI REVILLIOD, of Geneva, gave the third Kelynack Memorial Lecture to the Society for the Study of Addiction at the Medical Society of London on July 12. His subject was "Some Aspects of the Problem of Alcoholism in Switzerland." Discussing the drinking habits of his countrymen, Dr. Revilliod said the Swiss drinks 100 times more wine and four times less beer than the Englishman. The wine habit had an obvious relation to the agricultural economy of the country, and the vine had been cultivated in French Switzerland since the time of the Romans. The vineyards to-day, however, covered less than half the area they did 45 years ago.

Spirits had been distilled in Switzerland since the sixteenth century, at first in the form of cherry and plum brandy. Since the beginning of the nineteenth century "schnapps" had been made from potatoes, and the moral and material misery that this liquor produced among the peasants resulted in the introduction of the federal alcohol monopoly in 1885. The effects on the descendants of the schnapps drinkers were shown by the number of abnormal children and young men unfit for military service now seen in the country. In 1930 the monopoly was extended from potato distilling to that of seed fruits, and the consumption of spirits fell from about 6 litres to 2.5 litres per head. Aperitives were drunk widely, especially in the French-Swiss towns.

Beer, nearly all of which was brewed in the country, occupied an important place among the alcoholic beverages of Switzerland. At an establishment for patients in an advanced stage of alcoholism, beer-drinking alone was responsible for 48% of the cases. Fermented cider was drunk in some quantity in north-east and central Switzerland.

Dr. Revilliod remarked that a relatively slowly developing form of alcoholism was seen in his country. In observations made during the four-year period 1933–7, Professor M. Roch, head of the medical clinic at the Hospital of Geneva, demonstrated that alcoholism occurred in 48% of male patients coming under his care for various illnesses. Similar observations were reported from Zurich. Cirrhosis of the liver, detected at necropsy, was more frequent in Switzerland than in any other country. It occurred in about 7 to 10% of post-mortem examinations. The yearly admissions to Swiss mental institutions of patients suffering from psychoses due exclusively to alcoholism numbered 20 to 25% of male entrants and 3 to 5% of females. These figures declined during the war but rose in the period 1946–8.

Measures Against Alcoholism

In Switzerland, as elsewhere, said Dr. Revilliod, legislative measures against alcoholism were preceded by the action of groups of private citizens. In 1876 a young Swiss pastor, L. E. Rochat, launched the "Blue Cross" movement for reclaiming drunkards. Twenty-five years later this society, which was based upon total abstinence, had about 38,000 members in Switzerland and other countries. Auguste Forel, the psychiatrist, introduced the "Good Templar" order, which had the same object as the "Blue Cross" but no religious associations.

As another means of preventing the abuse of alcoholism the production of non-fermenting fruit juices, such as apple juice or grape juice, was encouraged. The taxation of alcohol in

Switzerland was at present very much lower than in other countries and did not amount to even 10% of the Swiss people's expenditure on drink, compared with 40% in Great Britain. The cantons were obliged, however, to allocate at least 10% of the revenue derived from the alcohol monopoly to the assistance of inebriates and the support of organizations engaged in this task. The cantons possessed the right to pass licensing laws, to restrict the number of public houses, and limit the serving of drinks to minors. The majority of the cantons also possessed a law which permitted the authorities to intern alcohol addicts for four to 12 months in a rehabilitation establishment. In Switzerland there were 75 anti-alcoholic dispensaries, in which alcoholics received advice, aid, and free treatment. If the gravity of their case required it, they were placed in a rehabilitation establishment or in a medical or psychiatric clinic. There were nine homes for inebriates—six for men and three for women—all free institutions subsidized by the State. Since 1947 a consultative commission of legislators and medical experts had been created to co-ordinate the efforts of the cantons and the associations in treating alcoholism.

The treatment of alcohol addiction by apomorphine had given good results in the department of neurology of the Hospital of Geneva. Intravenous injections of alcohol appeared to be efficacious for calming the delirium tremens. "Antabuse" had also been used in Switzerland, but was considered by the speaker to be not without danger.

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Report of Trustees for 1948–9

Sir Alfred Beit resigned his seat on the board of trustees in October, 1948, the trustees accepting his resignation with great regret. Sir Alfred had been a trustee since the death, in December, 1930, of his father, Sir Otto Beit, the founder of the Trust. Mr. R. A. Hornby has been elected as a trustee in his place. In April, 1949, the death of Lord du Parcq, who had been a trustee since 1947, was announced. The Right Hon. Lord Simonds, P.C., has been elected a trustee in his place.

The trustees noted with great satisfaction that during the year two of their Fellows, Dr. W. T. J. Morgan (1927–9) and Professor F. G. Young (1932–6) have been elected to the Fellowship of the Royal Society; and that the newly appointed secretaries of the Medical Research Council and the Agricultural Research Council—namely, Professor H. P. Himsworth and Dr. W. K. Slater, respectively—were Fellows in the years 1932–5 and 1923–8. Professor Himsworth was a member of the Advisory Board, and in view of his new appointment asked the trustees to accept his resignation. The trustees have appointed Professor G. W. Pickering in his place.

Elections to Junior Fellowships (normal value £600 per annum) have been made as follows: D. V. Bates, M.B., B.Chir., to carry out research on respiratory function, at the Dunn Laboratory, St. Bartholomew's Hospital, London; D. B. Carlisle, B.A., to study the mechanism of the production of the anterior pituitary hormones, at the Department of Zoology and Comparative Anatomy, University of Oxford; B. Cinader, Ph.D., to investigate the formation of multiple antibodies to a single antigen and to examine their properties, at the Lister Institute of Preventive Medicine, London; J. T. Davies, Ph.D., to investigate the nature of the excitation of living cells by examining the closely similar case of built-up films of materials which recent work suggests to be responsible for the permeability of cell walls, at the Royal Institution, London; D. T. Elmore, B.Sc., to examine the hydrolysates of nucleic acids, at University Chemical Laboratory, Cambridge; A. S. Jones, Ph.D., to study the immunochemistry of bacterial nucleic acid complexes, at A. E. Hills Laboratories, Chemistry Department, University of Birmingham; June Lascelles, M.Sc., to study the metabolic function of folic acid and para-aminobenzoic acid, at the Department of Biochemistry, University of Oxford; E. Reid, B.Sc., to study the pituitary growth hormone in relation to metabolic processes, at the School of Biochemistry, University of Cambridge; B. D. Wyke, M.B., B.S., to carry out quantitative studies on the electrical activity of the brain in patients with various types of central nervous system disorders of both organic and functional type, at the Department of Surgery, University of Oxford, and at the Radcliffe Infirmary, Oxford.

Nova et Vetera

AN ELIZABETHAN SURGEON

The Selected Writings of William Clowes, 1544–1604. Edited, with an Introduction and Notes, by F. N. L. Poynter, B.A., F.L.A. (Pp. 179. 15s.) London: Harvey and Blyth, Ltd.

William Clowes is a familiar figure in the medical history of this country, but few have any acquaintance with his actual writings. This is regrettable, since Clowes was not only one of the founders of British surgery but a writer whose works—in English, not in Latin—embody the spirit of the Elizabethan age. The reason certainly is that the works themselves are now amongst the scarcest of English medical works, and Mr. Poynter therefore deserves gratitude for his charming selection from Clowes's writings and for his scholarly introduction and editing.

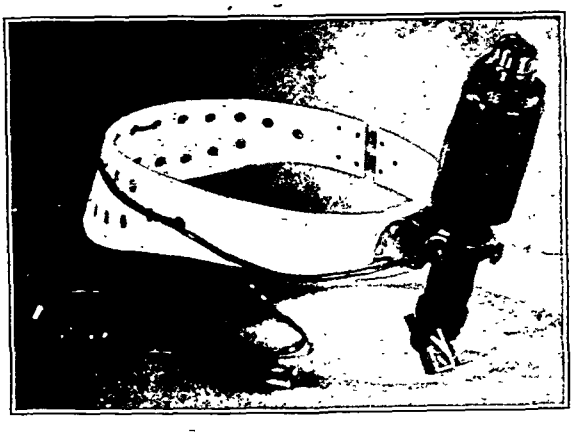
Clowes was born in 1544—and not in c. 1540, as the editor shows convincingly—and, after serving as a surgeon to Leicester's expedition to Normandy, became full surgeon to St. Bartholomew's Hospital and surgeon to Queen Elizabeth. He had great experience of military surgery, and quotes freely from the practice of the father of that branch of surgery Ambroise Paré. Of his three books the last, dealing with Struma or the King's Evil, appeared in 1602 and was not again reissued. His other two works, on the *Morbus Gallicus* and his *Prooved Practise for all young Chirurgians*, are a bibliographer's nightmare. They both went through several editions, changing their titles from time to time.

The work on surgery is the better-known and probably the more important from the medical aspect. This work is written in the form of a series of case reports, in which the author sets out in vigorous prose the cause of the conditions, the patient's relations with his doctors, and the treatment adopted by Clowes himself. Some of his operations are a great credit to his knowledge and experience. For the arrest of haemorrhage after amputation he employed a styptic powder which he tried out thoroughly before making it available for the use of others. He was not keen on the cautery, and in one passage he refers to "the hot glowing irons, which are very offensive to the eye." His instruments were on the whole those of Paré, modified to suit his own needs. These were rough days, and a surgeon who failed to cure—or even to please—a powerful patient stood a good chance of being maltreated by the household servants. At that date the surgeon had not become emancipated from astrological beliefs, and in one report Clowes says that one of his patients was in greater danger because he got his wound very near the full of the moon. He despised and hated all quacks, and he had no illusions about the hard work required before a man could become a good surgeon. "For anyone to suppose or dream that the art comes to a man by succession, because happily his father was a good surgeon, it is a paradoxical opinion, very foolish, absurd and fantastical."

In the time of Clowes syphilis was rife in this country. He says that at St. Bartholomew's half of all patients seen were suffering from that disease, and in five years over a thousand patients had treatment for it. In one passage he describes the tragic effect of inhalations of brimstone and mercury used in treatment. His small book on the King's Evil is of great interest also to the social historian. It contains an interesting account of the treatment which a patient adopted after having been "touched" by the Queen. "I never applied any medicine at all, but kept it [the lesion] clean with sweet and fresh clean cloths, and now and then washed the sore with white wine." A flight from the doctrines of Guy de Chauliac!

This book, carefully edited and well produced, should be of value to all who are interested in the history of surgery.

E. ASHWORTH UNDERWOOD.



Preparations and Appliances

HEADLAMP FOR E.N.T. SURGERY

Mr. G. W. MOREY, of Lincoln, writes: The problem of designing a satisfactory headlamp is a most difficult one which has interested me for more than ten years. In order to be efficient, such an instrument must conform to the following standards: (1) the light must be of high intensity; (2) the beam must be either coincident with, or parallel to and in line with, the visual axes; (3) the light must be focused into a clear homogeneous circle; (4) the whole apparatus must be light in weight and not be too bulky; (5) it must not get too hot.

Bulbs varying from 2 to 24 volts have been manufactured for my experiments. Unfortunately, though the higher voltage lamps gave considerably more light, they were unsuitable because of their size and heat. The present lamp employs an optically correct bulb of 12 volts, and has a specially wound horizontal filament giving 12 watts. The size of this bulb necessitates a rather bulky lamp-housing, but with an outer casing for heat dissipation the instrument is light and well balanced, and has been worn continuously for more than three hours without discomfort.

The homogeneous patch of light is of great intensity and sharply focused at 14 in. A feature of the lamp is an adjustable mirror positioned over the bridge of the nose by

means of which the beam can be directed horizontally (when, for instance, it is desired to do a tonsil dissection from the sitting position) or slightly downwards. Since the light axis is roughly parallel to and between the visual axes it is quite possible to use this instrument for endoscopy. If desired a hole may be made in the centre of the mirror so that, when adjusted over the eye, the operator may look along the beam itself. The barrel of the headlamp may be moved up or down or rotated after slackening off a clamping screw. Once adjusted to the user's individual requirements it need not be moved again. For certain ear, nose, and throat operations it may be found necessary to use magnifying spectacles. These fit comfortably under the mirror.

The headlamp is carried on a standard vulcanite headband and is connected by a convenient length of thin lightweight plastic wire to a small resistance. The shorter wire from the resistance to the mains terminates in a combination plug which will fit three varieties of sockets. It is fitted with a "through" switch, and this, when pinned by means of a towel clip under his gown, gives the surgeon complete control of his light. A small connecting plug-and-socket situated just below the switch allows the wire to be "broken" through the gown.

The lamp is manufactured by Theodore Hamblin, Ltd.

Correspondence

Distinction Awards

SIR,—As chairman of the medical committee of a teaching hospital I have recently received a signed circular letter from the chairman of the Distinction Awards Committee appointed by the Minister of Health, inviting recommendations for the grading of the consultant staff into those eligible for distinction awards and those not, and for the further classification of the first category into those meriting highest, second, and lowest awards respectively.

The letter also indicates that the Awards Committee would not regard with disfavour the delegation of this task by the medical committee to three or four of its number, these latter then to report their recommendations confidentially to the Awards Committee without notifying their colleagues what these are. The reason given for this invitation is the explicit admission that by itself the Awards Committee cannot satisfactorily discharge the responsibilities its members have undertaken, owing to lack of local knowledge.

Few, indeed, would dispute that the Awards Committee has a wholly impossible task, but many will regard it as being so not from any simple matter of lack of local knowledge but from its very nature, and likely to remain so no matter how freely the Awards Committee may farm out its responsibilities to small bodies reporting confidentially. It is one thing to grade a series of posts but quite another to seek to grade professional distinction, and it passes my comprehension that anyone who has spent his working life in medicine—unless as an administrator—could suppose that a grading of this order can be rationally and equitably accomplished. Even the assessment of purely scientific achievement in men of science, such as may be needed, for example, in the matter of election to membership of learned societies, is difficult enough, though here no vexing questions of money values arise. How utterly illusory, therefore, must be the hope of pricing "distinction" in the profession of medicine, where so many diverse factors of personality and achievement are involved and there are so many red herrings to be drawn across the trail.

It is idle to discuss this question unless we are candid about it. I ask, therefore, What constitutes "distinction" in medicine? Is it aptitude in the variegated arts of worldly success? Is it clinical wisdom, therapeutic fervour, or the acceptable usage of the forms of sickroom politeness? Is it the gift of training students or fruitfulness in original research? Is it the acquisition of seniority by lapse of years or a flair for planning the activities of one's colleagues? Is it to be a Mary or a Martha in medicine? How are these incommensurables, these diverse qualities of mind, heart, and worldly wisdom, to be comparatively assessed in terms of sterling? What are we to feel about a committee, apparently so unaware of the essential nature of what it is setting out to do that it can suppose that no more is necessary for its successful accomplishment than sufficient local knowledge?

I submit that there is no practical answer to these pertinent questions and that no committee can achieve a grading of a congeries of diverse human qualities, arbitrarily dubbed "distinction" for the occasion, that will satisfy the demands of reason or equity on the one hand or fulfil the natural desires of 96% of the consultant body on the other. Indeed, what more sure way of sowing discord amongst the members of hospital staffs could be devised than this setting up of an *ad hoc* body to price them as though they were professional soccer players; and, if university professors are to be differentiable like the rest of us, the invidious distinctions that are inevitable must make the most hardened cynic sorry for them.

Surely we may see in this another revelation of where the central control of medicine is leading us—namely, from the free status of a learned profession to that of a sub-group of that drab and alien abstraction "economic man." Is it too sanguine to hope that before this irrational affair has gone any further there will be some protest against it, and that some of the

ON GUARD in tinea territory

Activity is on the increase in swimming pools, baths and other centres of communal activity where the organisms responsible for mycotic infections find their hosts. Key measures to efficient control of such infection are prompt treatment of the developing case and planned protection among likely contacts . . and in both roles Mersagel is equally effective. Mersagel contains the powerful fungicide, phenylmercuric acetate, in a special water-soluble jelly base. It acts directly against the infecting fungi and maintains intimate contact with the seat of infection. Colourless and therefore clean to use, Mersagel does not normally irritate the skin and is suitable for the patient's personal application.

The Vitamin B_2 Complex

Vitamins of the B_2 complex play an important part in human metabolism and are therefore among the essential nutrients. Moreover, mild chronic deficiencies of these vitamins may be encountered, common symptoms being lassitude, chronic fatigue and lack of concentration.

Marmite has been found to be a particularly useful source of vitamins of the B_2 complex, as it is easily included in the diet in soups, in meat or savoury dishes, in sandwiches or as a drink. Many hospitals use it in routine catering as well as in restricted diets and it is specially recommended for expectant and nursing mothers and for children of all ages.

BARNET ENSIGN ROSS LTD. LONDON E 17

Cases such as those quoted are common in all communities. The series was of interest and value in describing briefly the personality and background of the type of patient to develop such symptoms. But all these patients might under different circumstances equally well have developed locomotor, effort-syndrome, neurological, or abdominal symptoms, or persistent headache, or any other of the myriad complaints that we are beguiled with. The diagnosis in each case was psychoneurosis, and the presumptive diagnosis of rheumatism was wrong.

This may seem a small point. But it is of first importance that all medical training should be directed towards recognizing the group of the psychoneuroses as a disease entity in whatsoever form it presents itself. The authors of the paper use their valuable material to show that psychogenic rheumatism is an entity by itself—which is nonsense—instead of to show that the difficulty of diagnosis between rheumatism and psychoneurosis is extremely difficult—which is all too true.—I am, etc.,

Emsworth, Hants. E. B. MCDOWALL.

SIR,—With reference to the article by Drs. William Tegner, Desmond O'Neill, and Anna Kaldegg (July 23, p. 201), surely an attempt to define "psychogenic rheumatism" as a clinical entity is somewhat unprofitable in the present state of knowledge of psychodynamics. While no one will be disposed to deny that "significant psychiatric abnormality" is more likely to be found in patients who show no evidence of an organic aetiological factor, it is certain that a considerable proportion of patients who do show organic pathology show in addition the operation of emotional factors (in spite of the authors' claim that in 13 controls the onset of illness appeared to be fortuitous). Detailed life histories of the control group would therefore have been of at least as much interest as the case histories of the test group.

A psychosomatic affection, as defined by Halliday,[1] is "a bodily disorder whose nature can be appreciated only when emotional disturbances . . . are investigated *in addition to* physical disturbances"; and, since the authors explicitly say that they are trying to formulate a psychosomatic condition, it is unreasonable of them to take as a diagnostic criterion "failure to conform to an established organic syndrome." It must be emphasized and re-emphasized that the psychological and physical approaches to diagnosis—and treatment—are not mutually exclusive. They are complementary. To say that a syndrome is either psychogenic or organic in origin is to oversimplify to a dangerous extent. It would be of considerable interest if the authors were able to correlate the complaint of rheumatic pain—with or without organic changes—with any particular type of personality or with any particular kind of emotional reaction-pattern. The short case histories published are of little help in this respect.

There are two other questions to which the answers would be interesting. (1) Would not group psychotherapy of the control group be worthy of study? Even if this is considered to be therapeutically valueless, it might help to clarify the personality pictures and emotional reactions of members of the group. (2) Is there any evidence that sufferers from rheumatism who have organic pathology regard their suffering as less "important, interesting, and worthy of sympathy" than those in whom no organic lesion is found?—I am, etc.,

Glasgow. JAMES R. MATHERS.

REFERENCE

[1] *Psychosocial Medicine*, 1948, London, p. 45.

SIR,—The article by Drs. William Tegner, Desmond O'Neill, and Anna Kaldegg (July 23, p. 201) is interesting in its content and clearly the result of painstaking work. Nevertheless, it suffers from a lack of precision in the definition of the precise syndrome under investigation. If the term "psychogenic rheumatism" is to serve any useful diagnostic purpose it must be clearly differentiated from psychoneurosis with accompanying somatic symptoms. Otherwise the whole trend of the argument is merely to prove the existence of something that is already widely accepted and described in standard textbooks.

The crux of the matter appears to be the use of the word "rheumatism." As far as can be seen it is being used because this group of patients display somatic symptoms of apparent skeletal origin that cannot be rationalized to a recognized pathology. But can this be accepted as a reason for the introduction of a new syndrome? Is there anything in the clinical description or diagnostic criteria that is not equally applicable to a psychoneurosis with somatic manifestations? Are we therefore to jettison the term psychoneurosis completely except in those patients where the somatic symptoms are absent?

It is hard to see what has been gained and easy to see the difficulties added to an already confused diagnostic picture. For the picture is confused. At one end of the scale there is the frank psychoneurosis with diffuse, sometimes contradictory, somatic symptoms. At the other end there is the "organic" non-articular rheumatism; the "neuralgia" of approximate segmental distribution; the fibrositis conforming to a recognized anatomical and physiological pattern. In between there is every shade of variation in the clinical picture presented.

Others may feel with me that an either/or approach to the problem is a fallacious simplification and that the approach should be in terms of the whole organism, psyche and soma, in relation to its environment.

The authors give five diagnostic points under the heading "Diagnosis and Treatment." I feel it would be wrong to pass over without comment the fifth point they list—"lack of response to physical treatments." Surely the essence of diagnosis is that it should be made on positive evidence, and this is generally recognized to be of particular importance in the psychoneuroses. Initial fruitless treatment based on an error in diagnosis undermines the confidence of the patient when the error is corrected and may tend to fix the somatic pattern more firmly. In addition subsequent treatment is rendered more difficult. We all make such errors frequently, but it should always be recognized primarily for what it is, an error, and not be elevated to the false dignity of a justifiable diagnostic "point." Furthermore, if we accept the validity of this view, the converse is equally acceptable. That is that the success of organic therapy in the relief of symptoms can be accepted as satisfactory proof that the organic diagnosis was correct. It only needs to be stated for the weakness of the reasoning to be apparent. The physiotherapy departments to-day bear witness to this faulty logic.—I am, etc.,

London, W.2. A. F. KENNEDY.

"Fibrositis" and Rheumatism

SIR,—It is a great pleasure to me to find Dr. W. S. C. Copeman (July 23, p. 191) ranging himself on the side of those who, like myself, no longer believe that the fibrous tissue in the muscles of the trunk becomes inflamed for no apparent reason and a disease called "fibrositis" results.[1] This support indeed helps, as Dr. Copeman claims, to turn over a fresh page. The question is, however, whether in connecting pain at the posterior aspect of the trunk with fatty lobules there he is turning the page backwards or forwards.

The fatty lobule idea arose in the following way. Finding that healthy young men were apt to suffer "fibrositic" pain in the lower back, Copeman and Ackerman[2] carried out post-mortem dissections on the lumbar muscles in a number of young soldiers, whether they had previously had backache or not. Had their assumption been securely based all might have been well. They found the muscles normal, but discovered lobules of fat in and about them, to which they then related "fibrositic" pain. Their article does not mention any investigation of the joints of the lower back. Their work thus rested on the dubious postulate that lumbar pain results not from articular but from muscular disorders and that it is in the muscles that the cause must be sought. Since Dr. Copeman now mentions disk lesions as a possible cause of lumbar pain he must be aware of the criticism invited by this muscular hypothesis.

The article, so exhaustive in other respects, mentions no physical signs whereby those cases can be distinguished in which tender deposits in muscle are and are not causing symptoms. Tenderness is stated to be considerable over lobules causing symptoms, less so over those that are not. This is not much help, and invites deception in cases of functional pain, when great tenderness is usually a prominent feature.

In fact there exists a very simple clinical test distinguishing between pain originating from a joint and from adjacent muscle. The function of muscle is to contract; if it does so fully and painlessly it cannot be causing the patient any pain, however tender or nodular it happens to be.[1] If a muscle is made to contract against such resistance that no movement takes place the tension on the muscle alters, but the joint remains stationary. If this attempt at movement causes or aggravates pain a muscle lesion is present. Since it is clearly desirable in any case of backache, before proceeding to palpation, to find out whether the lesion is muscular or articular, the joints and muscles should be tested separately first. This is the more important since referred pain, referred tenderness, myalgic spots, and trigger points are all commonly present at the site of pain in the dural and nerve-root lesions set up by disk protrusion. Trigger points, etc., result from the lesion causing pain; they are not primary.[4]

The clinician's only safeguard is to test each muscle individually against resistance; this singles out the muscle at fault—if there is one. This is the only way to find out whether or not to disregard the tender fat lobules that Copeman and Ackerman's own dissections, no less than everyday clinical experience, have shown to exist in many normal subjects without interfering with muscle action.

I have spent many years examining muscles and joints in this way and warmly commend it to those who would like to know at what structure to look for the lesion in cases of pain in the trunk or indeed about any part. Another virtue of this method is the quick detection of functional symptoms that it provides. When the active, passive, and resisted movements at a joint are tested, patients who have no local lesion must answer at random, and a self-contradictory pattern soon emerges. This system, so quick and simple to use by the examiner, confuses only those patients whose pain possesses no organic basis. We have found it, in reverse, a valuable criterion for detecting genuine local lesions in patients obviously neurotic; a common injustice is thus avoided. Dr. Tegner and his colleagues (July 23, p. 201) have done us a great service in emphasizing the frequency of functional symptoms in patients sent for physiotherapy.

Every layman knows what "rheumatism" is, but there exists no acceptable medical definition. If it is to mean anything at all (except of course in rheumatic fever) it must indicate some non-specific lesion of moving parts, chiefly of muscles and joints. My disagreement with Dr. Tegner is therefore only on nomenclature. Psychogenic "rheumatism" is self-contradictory, for if the lesion lies in the patient's sensorium the word rheumatism becomes inappropriate. "Functional" or "psychogenic pain" avoids all attempt at fusion of two incompatible words and provides an unambiguous alternative.—I am, etc.,

Strains of Bact. coli

SIR,—It seems quite likely that whenever a new publication appears on the subject of *Bact. coli* in relation to gastro-enteritis it will be found that the authors have coined a fresh name for the bacteria or the strains which they have isolated, although these may in fact be *Bact. coli* of the same serological type. Giles and Sangster[1] have stated that the strains they isolated in Aberdeen were identical serologically with those originally isolated at Hillingdon by Bray.[2] Drs. Joan Taylor, B. W. Powell, and Joyce Wright (July 16, p. 117) say that their strains are identical serologically with those of Giles and Sangster. It follows therefore that the D 433 strains of Dr. Joan Taylor and her colleagues are identical with Bray's original strains—a point which they did not make in their paper.

A summary of the nomenclature up to date is as follows. (1) Bray, 1945, and Bray and Beavan,[3] 1948, referred to these bacteria as *Bact. coli neapolitanum*, and the two strains in circulation among bacteriologists are called Lindsay and G. R. (2) Giles and Sangster, 1948, and Giles, Sangster, and Smith,[4] 1949, refer to the bacteria as *Bact. coli neapolitanum* type *alpha*. The *beta* type described by them, also in association with gastro-enteritis, is a serologically distinct type. (3) Taylor, Powell, and Wright, 1949, refer to the bacteria as *Bact. coli* D 433. I shall also immodestly add (4): in Holland, where these bacteria are being found (personal communication by Dr. ten Seldam), they are even referred to as *Escherichia coli bray*.—I am, etc.,

Zoster and Varicella in the Same Patient

SIR,—I was interested to read letters from Dr. A. Courts (June 11, p. 1052) and Dr. C. E. Taylor (July 9, p. 100) on the coexistence of herpes zoster and varicella. This combination cannot be considered rare and is in fact not uncommon in a hospital admitting infectious diseases from a considerable catchment area.

I have had five such patients under my care at the Neasden Hospital during the last three months. In one case the two manifestations appeared concurrently. In four cases the varicella developed in periods of 2–15 days after the appearance of herpes zoster and before it had healed. The nervous lesions involved the area of the first, second, third, and fourth lumbar roots in one case, and the second, third, and fourth sacral roots in another; in the remaining three cases it was the ophthalmic division of the fifth cranial nerve.—I am, etc.,

London, N.W.10. W. F. TWINING MCMATH.

SIR,—Further to the letters on this subject in the issues of June 11 (p. 1052) and July 9 (p. 100) we record particulars of another instance of this occurrence.

A male patient aged 84 years was recently admitted with well-marked herpes zoster involving the distribution of the posterior root of the second cervical nerve, accompanied by a typical attack of mild chicken-pox with characteristic distribution. No contact history with either complaint could be established, and he had no recollection of a previous attack of chicken-pox. The herpes zoster had preceded the onset of the varicella by six days.

As some of the immature varicellous lesions presented a haemorrhagic appearance and the base of some of the mature lesions was unusually hyperaemic, the possibility of vitamin-C deficiency was considered likely, especially as the patient admitted he seldom partook of fresh fruits. The ascorbic acid saturation test showed a considerable deficiency of vitamin C, although no other clinical evidence of deficiency was apparent.

Apart from the relative infrequency of this concomitance of chicken-pox and herpes zoster the case is additionally interesting in view of the very advanced age of the patient.—We are, etc.,

Ilford, Essex. J. H. WEIR. G. LAING BROWN.

Eclampsia and Peritoneal Haemorrhage

SIR,—I have read with much interest the article entitled "Rupture of Liver Associated with Parturition" by Dr. Jean R. C. Burton-Brown and Dr. J. A. Shepherd (May 28, p. 941). The prophetic suggestion of Rademaker that sudden death during eclampsia may sometimes be due to a ruptured liver was rejected by the writers of the article. The following brief notes of a case may prove of interest to your readers.

An East Indian woman of 30, para 8, was admitted to hospital with a history of having had a fit at 6 a.m. on Feb. 4. In the ward she had two fits—the first at 7.30 a.m., and the second at 9.30 a.m. At 4 p.m. her condition was satisfactory. The patient died suddenly at 5.15 p.m. Post-mortem examination revealed that the peritoneal cavity was full of fluid blood and blood clot. This had come from a very large subcapsular haemorrhage on the upper surface of the left lobe of the liver, which had ruptured the capsule at one point. The liver showed advanced eclamptic changes. The kidneys were pale and the cortex swollen. Nothing else abnormal was noted. Death was attributed to peritoneal haemorrhage and eclampsia.

—I am, etc.,

Port of Spain, Trinidad. JAMES A. WATERMAN.

The M.R.C.P.

SIR,—In the annotation "The M.R.C.P." (Aug. 6, p. 327) you ask a pertinent question, but do not suggest an answer. Thus you write, "When the College states that membership 'should signify a knowledge of general medicine that justifies further training as a consultant' the question must be asked, What further training is to be considered necessary, and who is to decide at the end of such training that the possessor of the M.R.C.P. is or is not 'a failed consultant'?" May I suggest several answers to your question?

First, it would be well if the M.R.C.P. were really considered to have the significance suggested by the Comitia of the R.C.P., because it would then be a qualification open to the general practitioner whose interests are mainly in general medicine, while it would also be a jumping-off place for the future consultant. If this were admitted there should then be a further examination for those who consider themselves fit to be consultants; and this examination should be adapted to the desires and capabilities of the individual candidates. Thus, for the men who wish to become general physicians (and let us hope that the race is not to become extinct), the higher examination would be one in general medicine; while for the aspiring specialist the examination would be, primarily at least, in his chosen subject. If the second suggestion were accepted there should be no limitation on the candidates in the matter of their "specialty," although if a man proposed a new subject he would have to justify his opinion that it deserved to be considered as a "specialty."

Such a plan would convert the present M.R.C.P. into a sort of primary examination for the Fellowship (for I suggest that those who passed the second examination should automatically become Fellows), while the whole machinery would be so flexible that there would be no difficulty in establishing new specialties so long as their exponents could convince the College that they were valuable. Details would, of course, have to be worked out. For instance, it might be wise for the regulations for the Fellowship to include a demand for a thesis or for submission of published work, while it would probably be wise to limit admission to the examination to those over the age of 30, or perhaps even over 34.

I am sure that some will ask how the member is to qualify himself for the Fellowship examination, and I feel strongly that he should have complete freedom in the matter, because, although the rudiments of a specialty can be taught, the task of really learning to be a specialist is a matter of personal initiative. Such a procedure would represent a real islet of freedom in our medical system, because each candidate could prepare himself as he thought best, although, of course, if he proposed to be examined in a "new" subject he would first have to convince the College that it was sufficiently important to be regarded as a specialty. I do no more than throw out these few suggestions, realizing that there may be some difficulties in carrying them into effect.—I am, etc.,

London, W.1. A. PINEY.

Mepacrine Dermatitis

SIR,—May I be permitted to suggest a small correction in your annotation (July 30, p. 275) on the above condition? The correction is in reference to the sentence, "It is now agreed that the ingestion of 0.1 g. or more daily of mepacrine for several months was the cause of this condition." I would point out that I stated in the article following that of Peterkin and Hair (*Brit. J. Derm. Syph.*, 1946, 58, 263) quoted in the annotation that I had observed lesions of mepacrine dermatitis in troops newly arrived in India—i.e., who had been on suppressive mepacrine therapy for a few weeks only.

The subject of mepacrine dermatitis has been one of interest to the North of England Dermatological Society in the past year. I have shown a case producing identical lesions—a case of rheumatoid arthritis under gold treatment. Other members of the Society have described similar cases, and Dr. Twiston Davies has mentioned two cases of cardiac oedema taking Guy's pill, producing lesions similar to those of mepacrine dermatitis. It appears therefore that mepacrine is only one of a number of drugs capable of producing this type of skin manifestation.—I am, etc.,

Bradford. ALLAN BIGHAM.

Syringes

SIR,—I observe that Dr. Douglas Gairdner has made a plea (July 30, p. 282) for the standardization of the Luer nozzle or hub fitting on all hypodermic syringes. I would like to reinforce this plea, as these syringes (being of American manufacture) are now unobtainable here and, as I have previously indicated (*Proc. R. Soc. Med.*, 1946, 39, 460), have particular advantages for ophthalmic work. This has been brought home to me with considerable force recently, as the few in my possession are wearing out and the contrast with the standard British fitting which I am compelled once again to use is very great.—I am, etc.,

Leeds. JOHN FOSTER.

Treatment of Stress Incontinence

SIR,—I join with my colleague Mr. Keith Vartan (July 9, p. 99) in admiring the technique of Mr. Wilfred Shaw's operation for the cure of stress incontinence. I do assert, however, that these arduous and technically difficult fascial sling operations are unnecessary. My operation[1] for the cure of this condition restores, underneath the urethra and particularly the neck of the bladder, those tissues which support these structures under stress, and is thus physiological in principle.

But it is results which count. In over 150 operations for the cure of stress incontinence (either for this condition alone, or combined with cystocele, or even vault prolapse) I have had two failures, one of course being in a "private" case. It has once been successful in "virginal" stress incontinence, and in another case where three attempts elsewhere had been made to cure this condition. These figures almost bring their own condemnation, for they show a success rate higher than in almost any constructive operation. They are, nevertheless, true. The fact remains, however, that, in my hands at least, the operation I have devised is so eminently successful that I can see no necessity for any form of sling operation. May I suggest that my operation be tried first, and if it be true that I am suffering from "the optimism which affects all inventors of operations for stress incontinence" I shall be only too glad to abandon my operation and join with Mr. Vartan in his enthusiasm for slings.—I am, etc.,

London, W.1. MORTIMER REDDINGTON.

Growth of Foetal Head

SIR,—In a recent paper by Blair Hartley[1] on the radiological detection of foetal abnormalities there occurs a very important paragraph which asks a question and carries a challenge demanding answer. He writes:

"A point to which further attention should be given is the statement which has been repeated in the past, that the foetal head continues to enlarge at the same rate during the later months of pregnancy. The late R. E. Roberts, for example, based his method of estimation of foetal maturity upon this assumption, but I have long had doubts regarding its correctness, and I have recently had the opportunity of examining the work of Dr. Sydney Josephs, who has already measured many foetal skulls by precision *x*-ray methods at 36 weeks and at birth, and he has been unable to show in the foetuses examined any increase in the diameter of the foetal head during the last four weeks of gestation. Indeed, is there any precise evidence to the contrary? It is important to emphasize the point that this applies only to normal-looking foetal skulls. It does not apply in hydrocephalus."

Now this appears to be a question to which a definite answer should be expected. Either the foetal skull increases its diameters by one-tenth of an inch (0.25 cm.) each week after

the thirty-sixth week or it does not. In all humility I suggest the radiologists are the only people who can answer the question accurately. If, as Blair Hartley suggests, the foetal head does not enlarge during the last four weeks, then all those who induce labour prematurely for apparent disproportion, either in primigravidae or in multiparae, will need to have a very clear idea of what they hope to achieve thereby. For, apart from the size of the skull, the mere bulk or weight of the foetus is the only other factor which can helpfully be reduced by premature induction of labour. And while it can be argued that such reduction in bulk is of great importance in breech delivery it can hardly be considered of common importance in cephalic delivery. It is for this reason that I suggest that this question is of no little significance.—I am, etc.,

London, S.E.18. ARCHIE G. MURRAY.

What is Social Medicine?

SIR,—In the *Journal* of July 16 (p. 125) you published a paper by Professor W. Hobson entitled "What is Social Medicine"? I happen to be one who has spent a lifetime in the Public Health Service and in the study and practice of preventive medicine, and I confess I have been somewhat mystified by the term "social medicine" which has become so fashionable in recent years, wondering in what way it differed from the public health work with which I had been connected. So, with the hope of having my doubts answered by Professor Hobson, I read his paper with great interest and expectation.

Although I must say I found the paper admirable in many respects, I could not find in it anything to show that social medicine in its objects and practice is very different from the old public health or preventive medicine as practised in this country during, say, the last 25 years. Social medicine is defined by Professor Hobson as the study of those environmental factors which affect health and the application of that study to the benefit of man. Surely this is nothing new, for such study and application have always been the role of public health work. Indeed, by quoting a sentence from the Memorandum of the Ministry of Health on the duties of medical officers of health to the effect that he, the medical officer of health, should endeavour to acquire a knowledge of the influences—social, environmental, and industrial—which may operate prejudicially to health in his district, Professor Hobson himself shows that all these factors were not overlooked in the old public health.

Professor Hobson says that the term "social medicine" is necessary because the older terms—public health and preventive medicine—are too limited in their scope, and that there are many factors not mentioned in the Public Health Acts which affect health. This is quite true, for the Public Health Acts deal mainly with requirements which can be enforced by law, but surely it is not true to say that public health work in the past has been confined to the enforcement of these Acts. Indeed, Professor Hobson himself supports this view when he quotes as an example of the need for studying factors outside the physical environment the researches of the late Dr. M'Gonigle on the health of people transferred from slums to new housing estates, but Dr. M'Gonigle was a medical officer of health, and no doubt he regarded these inquiries as part and parcel of his official duties. A study of the annual reports of medical officers of health for many years past, or the annual reports of Arthur Newsholme, George Newman, and their successors at the Ministry of Health, will demonstrate that many and varied researches have been made by these officers and their staffs into matters now considered to be the particular concern of social medicine.

It is true that during the last century and in the earlier years of this century public health work, apart from infectious diseases, was almost wholly concerned with drainage, water supplies, nuisances, and the like, but with the introduction of maternity and child-welfare and school medical services, followed by those for tuberculosis and venereal diseases, a great change came over the scene, and public health became infused with new interests, largely social in character. I have been concerned in this letter only to vindicate, if that is not too strong a word, the work of "public health" in the past, for I see clearly that great changes are impending, and are indeed unavoidable. I can see a great break-up of the environmental work of the medical officer of health, and if social medicine can infuse new life into a service which is threatened with death by inanition then I say, God speed to social medicine.

I hope Professor Hobson will forgive me the few mild criticisms which I have submitted, for I really enjoyed reading his paper and agreed with much he had to say, particularly where he pleads for a closer integration between preventive and curative medicine.—I am, etc.,

Torquay. THOMAS GIBSON.

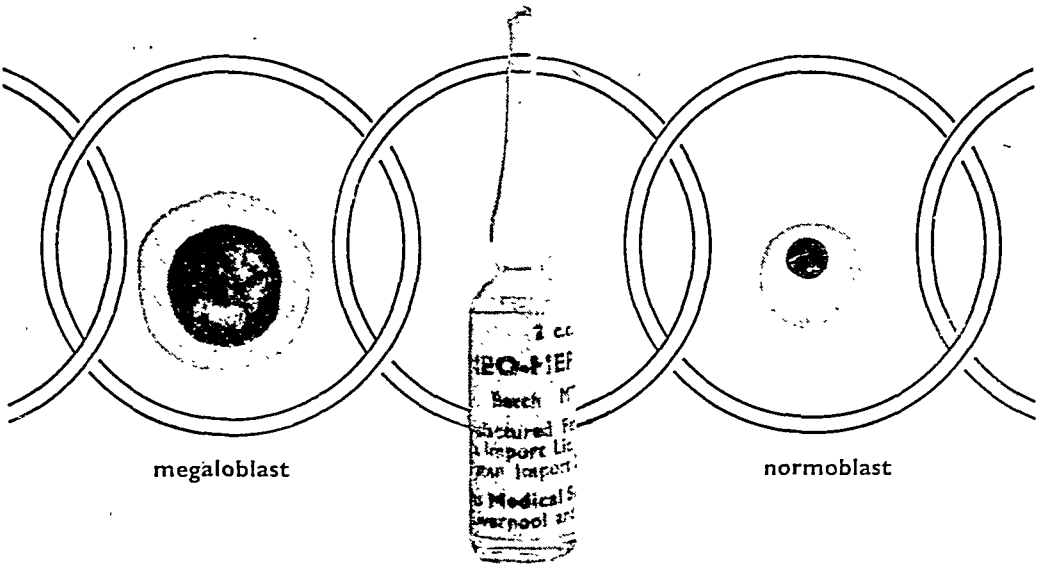
Intrauterine Manipulations

SIR,—With reference to the "overglove" for intrauterine and other manipulations described by Dr. J. A. Moyse (July 23, p. 230) I should like to mention a similar device designed by me and described in *Ginekologia, Polska* (1933) under the title "Sterile Access to the Uterine Cavity."

It consists of a rubber cuff about 4½ in. (11 cm.) long which extends at one end into a flattened shield with a metal frame attached to its edge. The longitudinal silk threads inside the rubber prevent stretching of the cuff lengthwise while the transverse stretch remains unhampered. The cuff is lined with gauze, the folds of which allow the cuff to be stretched transversely but not longitudinally. When in use the metal frame is attached with clips to the sterile sheet covering the operating field in such a way that the flat rubber shield covers the perineum and the surrounding skin of the vulva and the opening of the cuff comes opposite to the introitus of the vagina. Then the cuff may be inverted into the vagina when the hand passes through the vagina, or by a tubular or any other vaginal speculum.

Because the cuff is non-stretchable lengthwise, it cannot slip over the surface of the vaginal membrane when inverted, and it thus prevents the transfer of the bacterial flora from the lower to the upper part of the vagina. The gauze lining, which is turned towards the skin of the vulva and the membrane of the vagina, absorbs the mucous secretion which otherwise would be spread over the rubber surface of the cuff, and it thus prevents the transfer of organisms to the upper part of the vagina. The grasp of rubber in the frame takes the place of the hand pulling the "overglove" in Dr. Moyse's diagram, and thus the left hand is free. This is important, as the free hand should be placed on the abdomen over the fundus of the uterus when passing the other hand through the vagina to the uterine cavity.

The usefulness of the instrument was confirmed by the bacteriological examination of the pieces of the gauze lining taken from several places corresponding to the different levels of the vagina after the instrument had been used.



This instrument can be used for vaginal examination before or during labour, and for all obstetrical operations done by hand or instruments inside the uterine cavity. Although the consequences of infection are less dangerous now in the era of sulphonamides and penicillin, there is no doubt that Dr. Moyse is right in his opinion that the problem of the sterile access to the uterine cavity will always be one of great importance.—I am, etc.,

London, W.3. C. UHMA.

Breast-feeding

SIR,—Dr. F. H. M. Dummer will not mind an observation on one sentence of his excellent article (July 2, p. 14) from a classmate and fellow breast-feeding supporter. He says, "The number of babies completely breast-fed at 6 months was estimated at the low figure of 13.2%." Now rightly or wrongly this gives the impression that a higher figure would have been considered more desirable. If it is correct that it is necessary to give a breast-fed baby vitamin supplements from an early age, then presumably Nature, which could not have foreseen the generosity of the Ministry of Food, must have intended

NEO-HEPATEX

An essential link

Neo-Hepatex is an essential link in the chain of chemical reactions leading to normal erythropoiesis.

Within six to ten hours of the initial injection a remarkable change occurs in the megaloblastic marrow of pernicious anaemia. The nuclei of the megaloblasts become smaller and in 32 to 72 hours the megaloblastic picture has become normoblastic.

Neo-Hepatex is a non-toxic, highly fractionated, proteolysed extract of liver containing 10 microgrammes of Vitamin B_{12} per ml.. estimated by a combined method of paper chromatography and microbiological assay, using *Lactobacillus lactis* Dorner. Each batch is controlled by clinical tests on hospital cases of true, uncomplicated Addisonian anaemia.

LAWS OF MEDICINE

Goodell's Law

"When the cervix is as soft as one's lips, the woman is probably pregnant; when it is as hard as the tip of one's nose, the womb is most likely empty."

Goodell's gynæcological examination table. WILLIAM GOODELL, A.M., M.D. (*1829-94*) *was Professor of Clinical Gynæcology in the University of Pennsylvania.*

Goodell speaks of 'probabilities'; and even today there is no method of finding an infallible early answer to the question 'Is she pregnant?'

But much is now known about the hormone excreted in pregnancy urine. Boots' research chemists have contributed to this knowledge, and have been conspicuously successful in solving problems of hormone production.

In every branch of drug manufacture the constant aim of the Boots organisation is to keep pace with the latest advances made by medical science.

NOVUTOX

Self-Sterilising

LOCAL ANÆSTHETIC

½%, 1% & 2% SOLUTIONS

FOR

MINOR & MAJOR SURGERY

Absolutely non-toxic in therapeutic doses and tolerated by even the most sensitive tissues, Novutox has the added advantage that it possesses a remarkable chemo-therapeutic action which promotes very rapid and clean healing of wounds.

Available in:

½%, 1%, *and* 2% *Solutions:* - - - *BOTTLES of* 2 *ozs. and* 20 *ozs.*
1% *and* 2% *Solutions:* *AMPOULES* 2 *c.c.* *Boxes of* 12 *and* 100.
CARTRIDGES of 2% *Solution are available in boxes of* 20 *and* 100.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinofoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

PHARMACEUTICAL MANUFACTURING CO. LTD.
THE LABORATORIES, CHELTENHAM, GLOS.

Unanimous

OPINION is unanimous on the need for acid control in the *treatment of peptic ulcer.* It is the action of pepsin in a highly acid medium which prevents healing and predisposes to recurrence. This corrosive environment can be neutralised instantly by 'ALUDROX' therapy, which stabilises the stomach contents at pH 3.5—4.0, the optimum condition for healing since normal digestion is left unimpaired.

'ALUDROX' quickly relieves pain and in conjunction with a bland diet and rest promotes rapid healing of the ulcer.

'ALUDROX' is available in two forms: a suspension of 5·6% colloidal aluminium hydroxide in gel form, in 6 oz. and 12 oz. bottles and in 10 gr. tablets in boxes of 60 tablets.

'Aludrox' *Aluminium hydroxide gel*

that mixed feeding should begin much earlier than is the common practice.

The opponents of unconditional breast-feeding are, I believe, more opposed to breast-feeding being carried on too long, and to breast-feeding insufficient in quantity and not assisted by bottle-feeding after each breast-feed, than to breast-feeding in general. Possibly some reconciliation of the two viewpoints could be achieved along these lines, and, much more important, more mothers might be willing to breast-feed if they were told that weaning might be commenced at 4–5 months and completed at 6–7½ months, depending on health and size, instead of begun at 6 and finished at 9 months, as seems to be the common practice, quite unnecessarily, with bottle-feeding.—I am, etc.,

Saxmundham, Suffolk. JOHN SLEIGH.

Child-guidance Clinics

SIR,—According to your report (July 9, p. 90) of the meeting of the Sections of Child Health and Preventive Medicine on June 30, Dr. D. D. Payne suggested that reference of pupils to a child-guidance clinic should be by the school medical officer. His reported statement infers that other sources of reference should be closed. Not long ago, at a formal meeting arranged to discuss child guidance, a county medical officer of health said that in his opinion (an influential one) there was no need for child guidance in his county, and that in any case he did not believe in it.

My own experience of child-guidance clinics during the past six years has been that the majority of cases were referred by the family doctor, who surely is in the best position to know of the need for this highly specialized treatment.—I am, etc.,

Wimborne, Dorset. J. S. HORSLEY.

The Children Act

SIR,—Dr. John Dale (July 30, p. 284) does not appear to have read the Children Act. The Act is designed to enable local authorities, through their children's committees, to stand *in loco parentis* to children who for one reason or another fall into public care and thereby lose home background. In implementation of the Children Act the local authority children's committees are empowered to find individual children suitable substitute homes. It is also their responsibility to form proper liaison with the health and education committees of the council, and to ensure that children have adequate medical care and educational opportunity.

Dr. Dale can be assured that the care of children deprived of normal home life is not restricted to "health and hygiene," which still remains the prime concern of the health authorities.—I am, etc.,

Birmingham. HELEN MURTAGH.

Memorial to Sir John Fraser

SIR,—There must be many who would be eager to contribute to a memorial to Sir John Fraser, Bart., the late Principal of the University of Edinburgh. These would include his old students, his patients, and all those who had the pleasure of working with him in the course of the many public duties to which he gave himself so unsparingly.

With the consent of Lady Fraser and her family, a small committee has been formed to receive donations to a fund for this purpose. The form which the memorial might take is a matter for suggestion and discussion; it is felt, however, that the income of the fund might be applied in the provision of a scholarship, prize, or travel grant to be awarded annually to some young surgeon or surgeons of promise.

Contributions, which should not exceed ten guineas, should be sent to Mr. John Bruce, C.B.E., F.R.C.S.Ed., Department of Surgery, Teviot Place, University of Edinburgh, not later than Dec. 1, 1949.—We are, etc.,

EDWARD V. APPLETON.
F. E. JARDINE.
J. M. GRAHAM.
JAMES LEARMONTH.

Edinburgh.

POINTS FROM LETTERS

Petroleum Jelly as a Dressing

Dr. R. E. HOPE SIMPSON (Cirencester) writes: Sterilized petroleum jelly is much used as a dressing on raw areas in the belief that it will prevent gauze, lint, or other material from sticking. In fact it does no such thing, and dressings of this type adhere at least as firmly as dry dressings. There may be virtues in soft paraffin dressings, but not that of non-adhesion, and removal of such dressings after 24 hours is tedious and painful.

Mind, Machine, and Man

Dr. J. B. ELLISON (London, S.W.17) writes: While much entertained by Dr. J. A. V. Bates's letter (July 16, p. 177) on the alleged powers of electric computing machines, I must confess I was puzzled. It is not hard to see how, given the first move, an "electric brain" might always succeed in such a contest as the old game of nim. This game has an exact mathematical basis, so that actions needed to win could no doubt be transformed into mechanical operations which a machine would infallibly perform; juggling with rows of 0s and 1s is just what it does so well. But play chess? Can one envisage any machine on, say, the sixth move of a queen's pawn opening hazarding an advance of the king's pawn to its fourth square in order to avoid the "Cambridge Springs" variation because it knows that old Lobcockski (needing one point for first prize) has made a profound analysis of this variation and will be put off by such unorthodoxy? That is what I would call *playing* chess. And what would the poor machine do when confronted with a deep sacrificial combination? Could it refuse an offered queen (surely one of the highest priorities of "value"), foreseeing mate in the offing by "Philidor's Legacy"? This I do not believe—to speak of a machine playing a game is a fallacy of equivocation. But when it comes to the sonnet I am still more puzzled. First, as to these relative values. I wonder why Dr. Bates thinks that Miss Rita Hayworth on an alp is more "sonnetogenic" (to coin a word by analogy) than a Japanese soldier in Shoreditch. I know of a dozen modern poets who would certainly think the reverse. And how does the wretched machine know that it is looking at Miss Hayworth in the Alps rather than at Miss Lana Turner in the Himalayas or Miss Betty Grable in the Dolomites, and how would it assess the relative merits of such a galaxy? Of course it could decide nothing of the kind: the decisions are all made by the human mind outside that feeds the brute (that ghost horse of a recent radio discussion).

Mr. A. R. JORDAN (Dover) writes: As one interested in both chess and the ideas suggested by these new calculating machines I am intrigued by the letter of Dr. J. A. V. Bates (July 16, p. 177). I have some misgivings about the electronic chess player. No doubt it could play a legally correct game, but the difficulty would lie in the correct "instructions as to value." The standard openings have all been analysed for a few moves in this way, and invariably the limit is reached when a number of situations arise between which the greatest masters cannot decide the values. If the machine went on playing over to itself every possible sequence I have an idea that it would sooner or later find one where it went on for ever without a checkmate unless a new rule were introduced limiting the number of moves, and this would defeat the whole business. It still could not discover which was the "better" move. However, I have no doubt at all that a machine could be constructed which could solve any chess problem. . . . But could a machine be constructed to compose chess problems? I should say undoubtedly not. It would merely produce a series of end-games out of which some "mind" would have to select those which contain those elements of "difficulty" and "beauty" which constitute a true chess problem, and I do not see how such values could be put into the machine.

*** This correspondence is now closed.—ED., *B.M.J.*

Harrogate Appreciated

Mr. PHILIP GAUNT (Chairman, North Eastern Local Board of the Chartered Society of Physiotherapy) writes: On behalf of the members of the Chartered Society of Physiotherapy in this area, may I, through your *Journal*, offer our sincerest thanks for the generous concession made by the responsible committee in permitting us admission to the meetings of the Scientific Sections during the recent Annual Meeting of the B.M.A. in Harrogate? This was appreciated by all the members who were able to attend. The meetings were felt to be of real value and a help in keeping us scientifically equipped to enjoy our place as members of the team in which the medical profession plays the senior role. By example of the generous gesture of the Association during that week the right team spirit will always be maintained. Our thanks are also due to Dr. J. V. Wilson, Honorary Local Science Secretary, for the arrangements he made for us and for the patience he showed at a busy time in answering any requests and queries.

Obituary

T. STACEY WILSON, B.Sc., M.D., F.R.C.P.

Dr. Theodore Stacey Wilson, who died in Birmingham on July 30 at the age of 88, was the senior consulting physician of the United Birmingham Hospitals, sixty years having elapsed since he was appointed assistant physician to the General Hospital in 1889.

Stacey Wilson was educated at Grove House School, Tottenham, and at Edinburgh University, where he obtained the B.Sc. in 1881 and the M.B., C.M. and M.R.C.S.Eng. in 1883. In 1892 he proceeded M.D., and was awarded the Gold Medal for his thesis. After study in Vienna and Berlin he became resident medical officer of the Birmingham General Hospital in 1885, assistant physician in 1889, and honorary physician in 1892. In 1917, under the old rule which permitted only twenty-five years on the full honorary staff, he retired when only 56 years old, although he continued as extra physician until the end of the 1914–18 war. In 1919 he became consulting physician, and continued in active consulting practice until the last war. Wilson was lecturer in medicine to dental students and consulting physician to West Bromwich and other hospitals and institutions. He was twice married, and had one daughter.

An exact contemporary of Almroth Wright and Gowland Hopkins, Stacey Wilson displayed the enthusiasm of each but the scientific inhibitions of neither, though he exhibited the enterprising outlook of genius. Nervous in manner, quick in step and in speech, he was tall and spare and had brown hair and a moustache which turned to grey only in the last decade. Though he was a gentle and earnest physician who had lived for forty years in the Victorian era, retaining his frock coat until far into the present century, he never lost the sparkling optimism of youth, which, gleaming through his spectacles, induced him to observe new clinical signs and symptoms, to deduce hypotheses which appeared more attractive than likely, and to retain his interest and his convictions until some fresh observations drew his thoughts on to new trails. In the old-fashioned arts of palpation, percussion, and auscultation he was expert, though sometimes he claimed to perceive more than others could agree to. Chronic disorders of the stomach, the colon, and the heart interested him most.

He set out his views, with unfortunately little reference to the findings of other workers, in treatises on *The Early Diagnosis of Heart Failure, Thought Transference: Speculations upon Psychology and Religion, The Tonic Colon,* and other books. For those who gathered the grains of wheat from the mixed corn and chaff the exercise was stimulating and not without reward, but little that he did has survived the test of research and time, for the medical pendulum has swung from the qualitative region of clinical observation and speculation to the quantitative assessments of the laboratory, the machine, and the statistician. He did not tire of his patients nor they of him, and rewards in money or in status did not appeal to him. In earlier days he excelled at skating, and he was a competent golfer; until an advanced age he enjoyed the rod and the gun.

As a kindly physician he will long be remembered with appreciation by students and colleagues, who were stimulated by his untiring enthusiasm. Sufferers from chronic disease found in him a sympathetic attendant when other doctors had come to the end of their resources and of their patience.—H.W.F.

RALPH PEMBERTON, M.D.

Dr. Ralph Pemberton, professor of medicine at the Graduate School of the University of Pennsylvania and Honorary Fellow of the Royal Society of Medicine, London, died suddenly on June 17.

Dr. Pemberton was born in Philadelphia in 1877, and graduated at the university there successively B.S., M.S., and M.D. While still a hospital resident he became deeply interested in, and distressed by, the plight of the many chronic rheumatic patients for whom so little was done. His research and writings on the various aspects of chronic arthritis soon made him well known both in America and also internationally. After the first world war, in which he served as a major in the U.S. Army Medical Corps, he returned to his home town as Woodward Research Fellow in physiological chemistry, working for subsequent periods in Berlin and Strasbourg. On his return his wide and novel outlook and great energy inspired a group of younger men to join him, and resulted in the formation of his well-known arthritis clinic at the Abingdon Hospital, of which he was senior physician at his death.

In 1938 he became president of the Ligue Internationale contre le Rhumatisme. His illness tragically prevented him from attending its recent congress in New York, for which he had worked so hard. He was also National Consultant in Rheumatism, and ex-president of the American Rheumatism Association. In 1946 he was awarded the Gold Key of the American Congress of Physical Medicine in recognition of his research on arthritis and his contributions to physical medicine. A true "internationalist," he had friends all over the world, and was a great pioneer in the difficult field of medicine which he made his own.

W. S. C. COPEMAN.

HARRY HORSMAN McNABB, M.D.

The death on July 28 of Dr. Harry Horsman McNabb, of Manchester, is a great loss to ophthalmology, and especially to Manchester, where he practised for nearly fifty years.

Dr. McNabb graduated M.B., Ch.B. in 1898 at Owens College, Manchester, and proceeded M.D. in 1902. After spending a short time in general practice he started his ophthalmic training as junior and senior house-surgeon at the Manchester Royal Eye Hospital. He later became assistant honorary surgeon and then honorary surgeon. Nine years ago he was appointed consulting honorary surgeon and was active in hospital duties and a busy practice until a few weeks before his death. Among his appointments were those of clinical lecturer in ophthalmology at Manchester University and consulting honorary surgeon to many local hospitals. For many years he was surgeon to the Henshaw's Blind Asylum, and he was also vice-president of the Section of Ophthalmology at the Annual Meeting of the B.M.A. at Manchester in 1929. He was a member of many learned societies and often contributed to ophthalmic literature. One of these papers—on an "Alternative to Excision of the Sac in Dacryocystitis," in the *Transactions of the Ophthalmological Society of the U.K.*—advocated a simple, direct, and effective method as compared with the usual operation for excision of the lacrimal sac.

Everyone knew "Sandy" McNabb, and his social qualities were loved by so many that wherever he went he knew somebody and was known by somebody. He was very quiet in his manner and speech, but was always cheerful and had a twinkle in his eye. Dapper and helpful to everyone who asked for his advice or help, he never criticized anyone harshly, said an angry word, or lost his temper. The remarkable beauty of his hands was reflected

in his operative ability, which was a joy to watch. His operating, which was done very quietly, was perfect in its execution and ingenuity. A clinician all the time and a diagnostician of the first class, he was a mine of information on old and new ocular therapeutics, but never forgot the old methods, which often triumphed when modern treatment had proved inconclusive. As an expert ophthalmic witness he had few if any rivals, and his mere appearance in court carried weight for his client's case.

His persistent courage when in the middle period of his life he was smitten by phthisis, and how he announced it to his friends and fought it to a successful conclusion, was the admiration of all. When the tragic illness which caused the death of his elder son hit him sorely he never complained, but we all knew how afflicted he was. His married life was ideally happy, and his Scottish wife and he were both expert fishermen. To be entertained in their house was always a delight. The loss of "Sandy" McNabb is the loss of a friend, mentor, teacher, and colleague. His host of friends will sympathize deeply with his widow and son in their tragic loss. He was a perfect and gentle person of humour and understanding.—W.S.

WILLIAM ROBERT ACKLAND, M.R.C.S., M.D.S.

The death of William Robert Ackland on July 26 at the age of 85 years in a nursing-home at Clifton, Bristol, removes the last of five brothers distinguished in dentistry. He was the second son and last surviving child of the late Mr. and Mrs. Ackland, of Exeter. All the brothers qualified in medicine and dentistry, practising the latter. Each became one of the leading practitioners in London, Bristol, Bath, Exeter, and Bournemouth.

On leaving school W.R., as he was affectionately known, entered Charing Cross Hospital Medical School and the Royal Dental Hospital School, where he carried all before him. He obtained the Saunders Scholarship at the Royal Dental, and every prize it was possible to win—proving the most brilliant student of his year. He qualified L.D.S. R.C.S. in 1884, and took the M.R.C.S. in 1886, before the formation of the Conjoint Board. After acting as house-surgeon and demonstrator in operative dental surgery at the Royal Dental Hospital he joined one of the leading practitioners in Harley Street and was appointed assistant dental surgeon to Charing Cross Hospital. In 1888 the Bristol Royal Infirmary decided to establish a dental department with an honorary visiting dental surgeon. After some persuasion Ackland applied for the post. He was appointed, and returned to his beloved West Country, setting up in private practice at 5, Rodney Place, Clifton. His ability and charm soon won him a special place in the locality. Ackland may be looked upon as the father of the Bristol University Dental School. He was appointed lecturer and internal examiner in dental surgery at the Bristol University College. He retired from the staff in 1924, and was appointed consulting dental surgeon to the Royal Infirmary and the Minehead Hospital.

A member of various professional and learned societies —the British Medical and Dental Associations, the Bristol Medico-Chirurgical Society, and the Odontological Society of London—he took a keen interest in all their activities, delivering some interesting and original papers. His special interests were focal sepsis and its relation to systemic disease, and drainage of the maxillary sinus, for which he devised a special drainage tube. During his active years he occupied the chair of the Bristol Medico-Chirurgical Society, and was also president of the Odontological Society of London. In 1914–15, and again in 1933–4, he served as president of the Bath, Bristol, and Somerset Branch of the B.M.A., and in 1931–2 as president of the West Somerset Division.

After the passing of the 1921 Dental Act he was elected one of the original members of the Dental Board set up by the Government, and he was appointed an examiner to assess the fitness to practise of the unqualified practitioners. He also served on the General Medical Council. The University College of Bristol was granted its charter as a university in 1909. Ackland received the Service degree of M.D.S. in 1913 as a mark of appreciation of his work in the Dental School. During the 1914–18 war he served as major in the R.A.M.C. and acted as second in command of the 2nd Southern General Hospital in Bristol.

W.R. was deeply interested in the arts, and gathered together some beautiful specimens of china, antique furniture, and paintings. His waiting-room in Clifton was of perfect Georgian period. Among other interests was a love of horses: he spent most of his spare time hunting. A serious fall when out with the Beaufort Hunt resulted in concussion, and he had to give up his beloved sport. In 1917 he married the widow of Judge Buckle.

He retired from practice in 1937. When his wife died in 1945 her last surviving child, Mrs. Cotterell, and her husband came to live with him, caring for him in his last years. He died peacefully in his sleep, and his friends mourn the loss of a charming and most lovable man.

Medico-Legal

SALE OF PENICILLIN

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The Penicillin Act, 1947, was passed in order to restrict the sale of penicillin to qualified persons. Section 1 provides that no person shall sell or otherwise supply penicillin unless he is (*a*) a duly qualified medical practitioner, or a person acting in accordance with the directions of any such practitioner, or (*b*) a registered pharmacist or an authorized seller of poisons selling or supplying under the authority of a medical prescription. A shopkeeper, Mr. C. J. Coombs, who was neither a registered pharmacist nor an authorized seller of poisons, sold drugs and surgical appliances in his shop. On four occasions in August, 1948, he supplied penicillin ointment under a National Health prescription signed by a qualified medical practitioner. An inspector of the Pharmaceutical Society, Mr. W. R. Roberts, preferred informations against him for contravening the Act, but the Middlesex justices dismissed them, finding that the defendant was "acting in accordance with the directions" of a practitioner, that he sold or supplied the drug in accordance with the directions of a practitioner on each occasion, and that therefore he had committeed no offence. The inspector of the Pharmaceutical Society appealed, and the Divisional Court reversed the decision and remitted the case to the justices with the intimation that the offences had been proved.[1]

Lord Goddard, Lord Chief Justice, said in giving the judgment of the Court that if anyone could sell penicillin on a prescription under provision (*a*) there would be no object in provision (*b*). If the justices were right, a registered pharmacist would be at a disadvantage compared with an unregistered one. The words "in accordance with the directions of" a medical practitioner in paragraph (*a*) of Section 1 must, to be intelligible, include such cases as that of a doctor who told his dispenser to make up a penicillin preparation; but if the doctor gave a prescription to a patient that prescription must be made up by a registered pharmacist. A prescription, in other words, was not "directions" within the meaning of Section 1 of this Act.

[1] *Roberts* v. *Coombs*. *The Times*, May 5, 1949.

Medical Notes in Parliament

PENSIONS

Mr. BLENKINSOP on July 20 moved that the draft National Health Service (Superannuation) (Amendment) Regulations, 1949, be approved. He said these regulations cleared up minor difficulties which had shown themselves in the first year of the working of the superannuation scheme for the staff of the National Health Service. He understood that the various staff organizations were fully in agreement with them. The main provision was one under Regulation 10 designed to encourage those who had already retired on pension or were eligible to do so to continue in employment up to a further five years and thus earn an increased pension when they finally retired.

Mr. WALTER ELLIOT said it might be that further amendments would be necessary in the immense volume of regulations to which these amendments were proposed. In July, 1948, it had been estimated that the superannuation scheme covered 300,000 persons. This scheme obviously covered more people. He thought it covered the employees of the regional boards, the employees of the medical bodies, teaching hospitals, executive councils, and other bodies set up under the Act. He was informed that it also covered medical practitioners and dental practitioners, although not ophthalmic practitioners or chemists. He asked whether Regulation 10, in which employees were encouraged to continue in employment up to ten years beyond the possible retiring age, also covered those who returned to the Service, and what rebates or allowances were granted to those who had been out of the Service for a period. The strain on the Service just now was very great, and one of the simplest ways of relieving it was to recruit from those who had already been fully trained in one branch or another.

He remarked that Mr. Blenkinsop had not touched on the cost of the regulations. The estimated gross total for the Health Service this year was some £352,000,000, against which appropriations in aid amounted to £92,750,000. The contributions paid to the insurance scheme were only one-ninth of its cost. The insurance contribution of 6% paid by contributors towards the cost of the superannuation scheme amounted to a substantial sum. The appropriations made last year had been estimated at £44,000,000 for England and Wales, but rose to £62,000,000 when the estimates had been completed. Through these superannuation benefits there had accrued to the Exchequer in England and Wales £30,694,000. The only payment at present under the superannuation regulations was a sum of just under £2,000,000 for England and Wales. The Exchequer had a temporary surplus of over £30,000,000, which would run off as the liabilities began to accrue.

Apply to Specialists

Sir HUGH LUCAS-TOOTH said Regulation 16 (*c*) was applicable to specialists. Regulation 16 (*c*) of the original regulations enabled general practitioners within the Service to choose if they preferred to continue with a privately arranged insurance scheme to obtain benefit from the employing authority equal to the amount that the executive council would have had to put aside for their benefit if they had come within the general scheme. He thought the House would welcome the extension of this proposal to specialists. Under the original arrangements doctors who wished to continue their own insurance schemes had to give notice within three months of the appointed day in the original Act. Under the National Health Service (Amendment) Bill now passing through Parliament a number of general practitioners might come in at some future appointed day and might have insurance schemes which they wished to continue after the new appointed day. He feared this class might fall between the two regulations. They were not specialists, they were not covered by the new regulations, and they had not been within the schemes on the original appointed day.

Mr. BLENKINSOP pointed out that these amending regulations did not extend the scope of the scheme or bring in further groups with the exception of the small number of chaplains. They made the provision of the regulations more acceptable to those concerned but did not involve extra expense. Replying to Mr. Walter Elliot's questions, he said the new regulations covered those who would return to the scheme after a short break of service. The Government was providing for those who continued for an extra five years or for a shorter period under the scheme, for those who returned to the Service after a break, and for those who entered the Service after leaving some other superannuated service. The period was five years. Regulation 6 brought the injury provisions into line with the Civil Service provisions. Previously the Ministry of Health had followed the local government provisions. Persons who came back into service after a gap were covered in Regulation 10.

The provisions in Regulation 16 (*c*) of an option for part-time specialists to contract out had been made to meet a point raised by the British Medical Association. Practitioners coming in after the appointed day were not covered. The provision in Regulation 16 (*c*) was a special concession, and he doubted whether it could be extended. He did not deny there might be points worthy of consideration as the Ministry's experience extended. It would obviously be necessary to consider from time to time further amendments to the regulations.

Mr. WALTER ELLIOT trusted that Mr. Blenkinsop would look at the National Health Service (Amendment) Bill to see whether it was not possible in subsequent stages to bring in medical practitioners who would enter the scheme at a second appointed day and make it possible for them to be covered by the regulations. In view of Mr. Blenkinsop's pledge that this was not the occasion on which books were to be closed and no further amendments introduced the Opposition was willing to approve the regulations.

The draft National Health Service (Superannuation) (Amendment) Regulations were then approved.

Scottish Superannuation Regulations

The draft National Health Service (Scotland) (Superannuation) (Amendment) Regulations, 1949, came before the House of Commons on July 27. Mr. WALTER ELLIOT said these regulations covered large sums of money and considerable numbers of employees. For Scotland alone something like £2,500,000 was being brought in to diminish the apparent cost of the National Health Service, and the only payment out was a sum of £140,000. He inquired how the number of employees was related to the original number estimated. It was time the Government became more precise on these matters.

Mr. WOODBURN said these regulations amended the original regulations, but the adjustments were slight and the money involved was negligible. Nothing was added to the cost of the scheme. About 50,000 employees were covered, but there was no increase there.

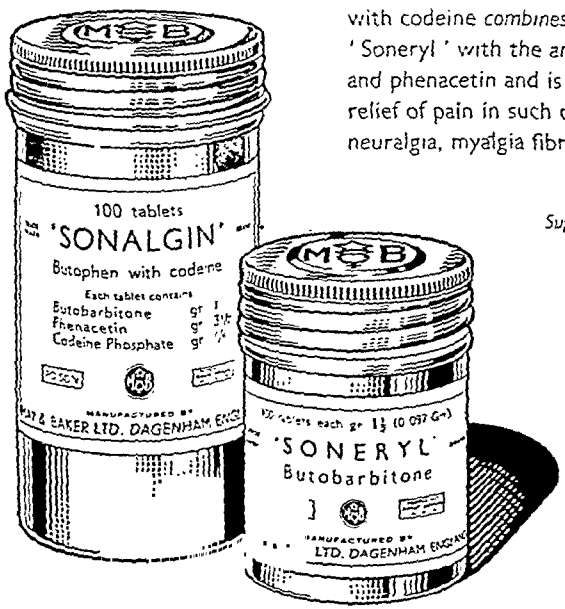
The House agreed to the draft regulations.

Parliament Adjourned

Parliament stands adjourned till Oct. 18. The Report and Third Reading of the National Health Service (Amendment) Bill are set down for Oct. 19 in the House of Commons. The Second Reading of the Nurses (Scotland) Bill is down for the following day.

Barnet Victoria Hospital

Mr. SPEARMAN asked the Minister of Health whether he knew that local concern had been caused by the decision of the North-West Metropolitan Regional Hospital Board to convert the Victoria Hospital, Barnet, into a maternity department for the Wellhouse Hospital, Barnet.



Mr. BEVAN replied on July 29 that if a petition was sent to him he would certainly consider it. It would be more appropriate if, in the first place, it was addressed to the regional hospital board, who had delegated powers for the planning and development of hospital services in their area which did not require them to obtain approval before they made changes in the use of particular hospitals.

. . . . . *for sleeplessness*

trade mark **'SONERYL'** the original brand of butobarbitone provides the ideal hypnotic for all cases of insomnia whether of mental or physical origin. It is rapid in action producing a natural dreamless sleep within half an hour, which is maintained from six to eight hours.

. . . . . *where sleeplessness is associated with pain*

trade mark **'SONALGIN'** brand butophen with codeine combines the hypnotic properties of 'Soneryl' with the analgesic actions of codeine and phenacetin and is of particular value in the relief of pain in such conditions as dysmenorrhœa, neuralgia, myalgia fibrositis and migraine.

Supplies :

'Soneryl' tablets in containers of 12, 25, 100 and 500 x gr. 1½ (0.1 Gm.)

'Soneryl' suppositories in boxes of 5, each containing gr. 3, gr. 5, or gr. 10 of the active product

'Sonalgin' tablets
butobarbitone gr. 1 (0.065 Gm.),
codeine phosphate gr. 1/6 (0.011 Gm.)
phenacetin gr. 3½ (0.227 Gm.)
containers of 25, 100 and 500.

Treatment of exudative dermatoses

Investigation has shown that titanium oxide possesses dessicant properties considerably greater than the powders usually employed in the treatment of the dermatoses. Siccolam contains 21% titanium oxide together with zinc oxide and kaolin in a fat-free base. Laboratory tests have indicated that Siccolam is seven times more effective as a dessicant than zinc oxide (*Brit. J. Dermatol. & Syphilis*, June 1941, vol. 53, p. 177). There are no contra-indications to the use of Siccolam and it may be applied before a final diagnosis has been made without prejudice to subsequent treatment. Anti-bacterial agents or other medicaments may be incorporated with Siccolam if desired.

COLLAPSIBLE TUBES of 2 and 4 oz. CONTAINERS of 1 lb.

Cancer Research

Brigadier MEDLICOTT on July 28 asked Mr. Herbert Morrison whether, in view of the serious increase in deaths from cancer during the last 30 years, he would make a statement on the research now being conducted under the auspices of his department, or with his encouragement; and, in particular, say what joint research or co-operation with America was taking place.

Mr. MORRISON replied that research on cancer formed a very important part of the programme of the Medical Research Council. It was also promoted, with official encouragement, by bodies such as the Imperial Cancer Research Fund and the British Empire Cancer Campaign. There was particularly close co-operation in this field between British workers and their colleagues in America. The Medical Research Council's expenditure on cancer research was estimated at £145,000 for 1948–9 and at perhaps £200,000 for 1949–50. Mr. Morrison declared that real progress was being made in research and that the limiting factor was not finance.

Free Drugs for Private Patients

Mr. H. D. HUGHES asked on July 28 what would be the increased cost of allowing private patients to obtain drugs recommended by their doctor free of charge.

Mr. BLENKINSOP said that if the estimated annual rate of expenditure on the pharmaceutical services were proportionately increased in respect of the 5% of the population of England and Wales not on doctors' lists the increase would amount to about £1,000,000.

Pneumoconiosis

Mr. JAMES GRIFFITHS states that from Jan. 1, 1949, to June 25, 1949, assessments under the Industrial Injuries Act of disablement due to pneumoconiosis were made at 100% in about 20 cases, and at less than 100% in about 1,900 cases. In addition, in the same period 276 men who had left the industry before July 5, 1948, were certified under the Workmen's Compensation Acts; of these 134 were found to be totally disabled. During the corresponding period of 1948, 843 men were certified under the Workmen's Compensation Acts, of whom 87 were found to be totally disabled. These figures are not strictly comparable with those for 1949.

Tuberculosis Examinations.—Foreign workers recruited under official schemes for which the Minister of Labour is responsible are required to undergo a general medical examination and an x-ray examination to detect tuberculosis before they are accepted and brought to this country. In proportion to the numbers recruited cases of serious sickness have not been numerous, but as these workers are mostly displaced persons the privations which they have undergone may have resulted in some cases in breakdown in health after their arrival.

Glasses and Wigs.—At a rough estimate about 4,500,000 pairs of spectacles have been supplied under the Supplementary Eye Service. Between 3,000,000 and 4,000,000 pairs are on order. No information is available as to the number of dentures. Up to May 20, 8,000 wigs were ordered, and 2,600 supplied, through the Ministry of Pensions on the advice of specialists.

Dental Emergencies.—Procedure for emergency treatment under the Health Service by dentists of patients who are in pain is being used for over 25,000 patients a week.

Bristol Patients.—The average number of patients on the panel of doctors at Bristol on April 1 last was 2,300—the highest something over 4,000, the lowest 2.

Ophthalmic Opticians.—The number of ophthalmic opticians in England and Wales now employed in providing optical treatment within the National Health Service is 5,662. The Government hopes for an increase in the number.

According to a report in *The Times* (June 30), the chairman of the British Tourist and Holidays Board has stated that the "clean food" campaign which the Board began a year ago has been a great success, and efforts will be continued to raise the standard of hygiene in hotels, restaurants, and cafés. "The problem of hygiene in the catering industry," the chairman said, "is more than 70% a problem of personal hygiene."

Universities and Colleges

UNIVERSITY OF LONDON

Dr. John Thomas Aitken has been recognized as a Teacher of Anatomy at University College, and Dr. Robert Douglas Harkness has been granted probationary recognition as a Teacher of Physiology at University College for a period of two years from June, 1949.

Shenley Hospital, St. Albans, has been added to the list of recognized mental hospitals for the degrees of M.B., B.S.

The Mary Scharlieb Research Studentship for 1949 has been awarded to George Philip Arden, F.R.C.S., for one year in the first instance. The studentship, which is of the value of £250, is tenable for one or two years and is offered to graduates of the University who are either registered medical practitioners or in possession of qualifications which in the opinion of the Senate would enable them to undertake postgraduate medical research.

The A. H. Bygott Scholarship for 1949 has been awarded to Howard Temple Phillips, M.B., B.S. The scholarship, of the value of approximately £100 and tenable for one year at the London School of Hygiene and Tropical Medicine, is offered annually for the course for the Academic Postgraduate Diploma in Public Health. Candidates must be registered medical practitioners who are serving in public health departments or who intend to enter or have already entered the Public Health Service either at home, in the Dominions, or in the Colonies.

Robert Knox, M.D., M.R.C.P., has accepted an invitation to the University Chair of Bacteriology, tenable at Guy's Hospital Medical School, from Oct. 1.

The title of Professor of Bacteriology in the University has been conferred on Frederick Robert Selbie, M.D., Ph.D., D.Sc., in respect of the post held by him at Middlesex Hospital Medical School.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on July 28, with Sir Cecil Wakeley, President, in the chair, it was decided on the recommendation of the Faculty of Dental Surgery to institute an annual Dental Lecture to be entitled the "Lord Webb-Johnson Lecture" to commemorate the indebtedness of the dental profession to Lord Webb-Johnson.

Dr. J. Hall Best, President of the Twelfth Australian Dental Congress, was elected to the Fellowship in Dental Surgery.

The Hallett Prize for 1949 was awarded to Graham Roland Anderson (Queensland).

The date of the annual meeting of Fellows and Members was arranged for Wednesday, Nov. 9.

Diplomas of Membership were granted to the 117 recipients of the L.R.C.P. whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of Aug. 6 (p. 340).

Diplomas in Public Health, in Tropical Medicine and Hygiene, and in Medical Radio-Diagnosis were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN PUBLIC HEALTH.—A. Bashir, B. A. Bhatti, Mary Brooks, T. H. Elias, J. E. Francis, Joan K. Griggs, W. E. Hadden, D. G. Levis, G. K. Lim.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—J. P. Satterwhite, A. F. H. Stewart, S. W. W. Terry.

DIPLOMA IN MEDICAL RADIO-DIAGNOSIS.—D. Chisholm, J. J. Wallis.

The following hospitals were recognized under paragraph 23 of the Fellowship regulations: Poplar Hospital, London (resident medical officer, resident surgical officer, and senior house-surgeon); St. Stephen's Hospital, London (two surgical registrars and one house-surgeon); Maidenhead Hospital (resident surgical officer).

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.S.Glas: A. E. Barr, Margaret H. Batty, Constance E. Belton, W. E. Bennie, M. C. Berenbaum, L. H. Berman, D. G. Brown, E. L. R. Brown, W. F. Blair, Diana P. M. S. Cargill, S. L. Chinchin, L. I. Davidson, G. M. Daya, J. Devine, D. J. Docherty, F. Doherty, Helen E. Ferguson, L. M. Foegal, V. Gallone, G. T. W. Gowdie, Joan F. Greaves, Muriel S. Hill, D. D. Hillier, J. B. M. Hirst, H. Jackson, J. Jackson, R. G. Jacomb, Ruth W. Joelson, Valerie Jones, H. Justitz, J. D. Keir, Rosemary C. Kennedy, R. C. Lamberty, V. K. Moodaley, D. B. Murray, R. McNeill, G. S. C. Nzegwu, Rosemary A. Page, B. Raeburn, Gwyneth Richards, Helen M. Roberts, F. Starer, C. Stewart, M. Stock, Christina E. C. Taylor, T. H. Walker, B. T. Walters, D. B. S. Watt, D. Ll. Williams.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 23. [No. 29

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

The total numbers of notifications in England and Wales for the week ended July 30, 1949, were: poliomyelitis 147 (96), polio-encephalitis 22 (3). (Figures for the previous week are shown in parentheses.) Counties reporting more than one case (poliomyelitis and polio-encephalitis together) were: London 20 (7), Bedford 2 (0), Berkshire 2 (3), Cambridge 2 (1), Chester 6 (0), Cornwall 8 (1), Dorset 2 (0), Durham 2 (1), Essex 8 (4), Gloucester 3 (2), Hertford 3 (1), Kent 3 (0), Lancashire 12 (8), Leicestershire 5 (6), Lincolnshire, Lindsey 4 (1), Middlesex 13 (11), Nottinghamshire 3 (1), Oxfordshire 2 (0), Southampton 7 (8), Suffolk West 4 (3), Sussex West 4 (1), Warwick 6 (1), Westmorland 2 (0), Yorkshire East Riding 2 (1), Yorkshire West Riding 24 (17), Denbigh 2 (0), Glamorgan 3 (0), Monmouthshire 2 (0).

The rise in notifications this week has been considerable, and it is unlikely that a consistent fall can be expected yet. However, in comparison with 1947 the rise this year has been irregular, and in the week ended July 26, 1947, corresponding to the week under discussion, there were 302 notifications of poliomyelitis and 34 of polio-encephalitis. In 1947 the peak was reached in the week ended Sept. 6 (thirty-sixth week), but notifications in the week ended Aug. 16 (thirty-third week) were almost as high, and there was a small recession in the two intervening weeks.

The geographical distribution of the notifications underwent little change. The largest centres of infection were Yorkshire West Riding 17; Middlesex 10 (Hornsey M.B. 5, Finchley M.B. 4); Southampton 8 (Southampton C.B. 4); Lancashire 7; London 7; Devonshire 7.

Quarterly Returns for England and Wales

The birth rate during the March quarter was 17.4 per 1,000 compared with an average of 18.2 for the first quarter of the five years 1943–7. The infant mortality was 40 per 1,000 live births and was the lowest rate ever recorded for a first quarter, being 1 below the rate for the first quarter of 1948 and 24 below the average rate of the 10 preceding first quarters. The general death rate was 15.0 per 1,000, and was 3.7 above the rate for the March quarter of 1948 and 0.2 above the five-years average of 1943–7.

Quarterly Return for Northern Ireland

The birth rate during the March quarter was 21.8 and was 1.0 below the average rate for the five preceding first quarters. Infant mortality was 55 per 1,000 registered births and was 2 above the rate for the corresponding quarter of last year but 16 below the five-years average. The general death rate was 14.0 per 1,000—an increase of 1.2 on the rate for the March quarter of 1948 but 1.6 below the five-years average. There were 118 deaths from the principal epidemic diseases; they included 49 from influenza, 45 from diarrhoea and enteritis, and 13 from whooping-cough. Deaths from pulmonary tuberculosis numbered 197, and there were 34 from other forms; these were 39 and 31 respectively below the average for the five preceding first quarters.

Quarterly Return for Eire

A birth rate of 21.9 per 1,000 was recorded during the March quarter. This was 0.3 above the rate for the preceding first quarter. Infant mortality was 55 per 1,000 registered births and was 8 below the rate for the March quarter of 1948. The general death rate was 14.7 per 1,000 and was 0.5 above the rate for the preceding first quarter. Deaths from the principal epidemic diseases numbered 125, and included 72 from diarrhoea and enteritis, 35 from whooping-cough, and 12 from measles. Deaths from pulmonary tuberculosis numbered 631, from other forms 153; these were 61 and 11 respectively below the totals for the first quarter of 1948.

Discussion of Table

In *England and Wales* decreases in the number of notifications were reported for measles 324, whooping-cough 180, diphtheria 28, and acute poliomyelitis 16, while increases were notified for scarlet fever 114 and dysentery 22.

The largest falls in the notifications of measles were London 111, Lancashire 68, and Devonshire 61, while the largest rise in incidence was Kent 56. The only large variations in the local trends of scarlet fever were rises in Yorkshire West Riding 31 and London 25. The chief features of the returns of diphtheria were decreases in London 10 and Warwickshire 9 and a rise of 8 in Cheshire due to an outbreak of 7 cases in Birkenhead C.B. The only fluctuation of any size in the returns for whooping-cough was a decrease of 30 in Lancashire.

The chief centres of paratyphoid fever were Lancashire, Liverpool C.B. 25, and Cheshire, Birkenhead C.B. 11. The rise in dysentery was mainly due to Lancashire, where the notifications rose from 5 to 26 (Oldham C.B. 12 and Liverpool C.B. 11). A further 33 cases of dysentery were reported from the outbreak in Warwickshire, Warwick R.D. Of the 172 cases of food-poisoning 82 were notified in Yorkshire West Riding.

In *Scotland* a decrease occurred in the number of notifications of measles 57 and scarlet fever 16; increases were reported for dysentery 21 and diphtheria 8. The rise in dysentery was contributed by Glasgow, where the notifications rose from 15 to 45.

In *Eire* decreases were recorded in the number of notifications of measles 64, whooping-cough 46, and diarrhoea and enteritis 18. An outbreak of 23 cases of measles was notified from Kerry, Listowel R.D.

In *Northern Ireland* the only fluctuation of any size in the returns for the country was a decrease of 38 for measles.

Week Ending July 30

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,045, whooping-cough 1,795, diphtheria 98, measles 4,266, acute pneumonia 263, cerebrospinal fever 27, acute poliomyelitis 147, dysentery 94, paratyphoid fever 50, typhoid fever 3.

Medical News

Visit to Canada and the U.S.A.

Sir Lionel Whitby, Past President of the B.M.A., is visiting Canada and the U.S.A. from the middle of August to the beginning of October, and will attend a number of Divisional Meetings of the Canadian Medical Association, including the Maritime States.

Contaminated Pears

The Ministry of Food states that some pears now arriving from Italy still retain a slight trace of an antiparasitic spray. We understand that the spray contains a small amount of arsenic. It can be removed by wiping with a cloth, and the health authorities are examining all the pears now arriving to ensure that this is done where necessary before the fruit is offered to the public. The Italian authorities have taken steps to prevent further affected fruit from being exported.

New Diploma in Psychological Medicine

The Royal Medico-Psychological Association will hold the first examination for its diploma in psychological medicine in November this year. Applicants should apply before Sept. 1 to the Registrar, Southfield, Shipton Road, York. Applications for recognition as training schools for the diploma should be sent to the Secretary of the Association, 11, Chandos Street, Cavendish Square, London, W.1. Further information about the examination may be obtained from the same address.

British Society of Periodontology

This society has recently been formed for the purpose of promoting the study of periodontology. Dr. E. W. Fish has been elected president. The society will provide the means for those interested to meet and discuss their problems. It will meet during the winter months, and papers, communications, or demonstrations will be presented. The initial membership is about forty. Correspondence may be addressed to the hon. secretary at the Institute of Dental Surgery, Eastman Dental Clinic, Gray's Inn Road, London, W.C.1.

N.A.P.T. Scholarship for Scottish Nurse

A scholarship of £100 to £150 will be awarded by the National Association for the Prevention of Tuberculosis to a registered female nurse working at the time of her application in a hospital in Scotland. The scholarship will enable her to spend a period of from three to six months in postgraduate study in hospitals or clinics in (*a*) Scotland, (*b*) England, or (*c*) Scandinavia. Candidates should state age, qualifications, previous experience, and reasons for wishing to do postgraduate work in tuberculosis, and should affirm their intention to continue in tuberculosis work after attaining the scholarship. Application should be made by Nov. 1 to Miss A. J. Weir, Scottish Secretary N.A.P.T., 65, Castle Street, Edinburgh, 2.

Second Century

The *Registrar-General's Return* for the quarter ended March 31, issued on Aug. 5, is No. 401, and inaugurates the second century of its publication. The statement which appeared in the first of these *Returns* is of even more significance now than it was then: "The present arrangement will show, at short intervals, how many marry, how many are born, and how many die in England; and will thus appear in time to enable the public and the Legislature to take the indications which the returns may furnish into account in the conduct of affairs." Some results of the sample Sickness Survey included in it are published in the *Supplement* at p. 79.

Rationalist Press Association

The fourth Annual Conference of the Rationalist Press Association was held at Oxford on Aug. 5–9. Dr. Alice M. Stewart said that during the last five years a few medical schools in this country had established departments of social medicine in an attempt to bridge the gap between hospital and domiciliary medicine. At present over 90% of the teaching was done by specialists who were concerned with the minutiae of disease but need have no first-hand experience of general practice. There was a tendency for medical students, the majority of whom were destined to become general practitioners, to overrate the importance of diagnosing and treating established disease, and to underrate the importance and also the interest of preventive medicine. Departments of social medicine provided a setting in which clinicians might work outside hospitals and yet retain contact with medical students. They should therefore be in a unique position to institute new lines of research and to explore new methods of teaching. At present they were finding difficulty in obtaining full co-operation from other departments which are slow to recognize the need for fundamental reform. Dr. C. P. Blacker said that recent preoccupations with declining fertility had closed their eyes to the fact that over much of the world the Malthusian dilemma still pressed. The possible effects of birth control methods in backward countries must be considered. Parental instincts, dissociated from their sexual precursors, would increasingly determine fertility. Few social innovations were unreservedly beneficial, and new problems might emerge. Surgeon Vice-Admiral Sir Sheldon F. Dudley said that our boasted and boosted National Health Service was in reality a medical or ill-health service, an institution for taking care of the sick and unhealthy at the expense of the healthy. It would require years of experimental research by sociologists and psychologists before we could hope to discover what degree and kind of social security would produce the greatest health and energy for the greatest number of the citizens.

Institute of Venereal Disease Technicians

The inaugural conference of the Institute was held at Manchester on July 23, and was attended by representatives from each regional hospital area. Mr. R. A. Henderson, the honorary secretary, said that the primary function of the Institute would be the recruitment, training, and setting of professional examinations for selected State-registered nurses, with the object of producing a highly skilled V.D. technician of a standard and quality which venereologists would have confidence in. Before they could get recognition they must have the support and approval of the venereologists.

Diabetics and Sweet Rationing

When sweet rationing is started again on Aug. 14 diabetic patients will still be able to obtain packets of glucose tablets for use in emergency without surrendering personal points. These tablets are prepared specially for medicinal use, and chemists should reserve them for customers whom they know to be diabetic. By the terms of the new Ministry of Food Order patients will not be able to have glucose barley sugar ordered for them on Forms E.C.10. A doctor may, if he wishes, give a patient an "approved order" (not being an E.C.10), which may be taken to a chemist only and the barley sugar obtained on payment by the patient.

Medical Library Association

The 48th annual meeting of the Medical Library Association was held at Galveston, Texas, on April 10–14. It was announced that an "Interim List of U.S.A. and Canadian Holdings of German Medical and Dental Periodicals, 1939–48" would be ready for distribution within a few months. Officers elected for the year 1949–50 were: president, Dr. Sanford V. Larkey, librarian, Welch Medical Library, Baltimore; vice-president (president-elect), Miss Marjorie J. Darrach, librarian, Medical Science Department, Detroit Public Library; honorary vice-president, Admiral George W. Calver, physician to Congress, Washington, D.C.; secretary, Miss Helen Hlavnac, New York University, College of Dentistry Library; treasurer, Mrs. Edith Dernehl, librarian, Marquette University Medical Library, Milwaukee, Wisconsin. The 49th annual meeting will be held at Boston in June, 1950.

Medical Sickness Society

The annual general meeting of the Medical Sickness, Annuity and Life Assurance Society, Limited, was held in London on July 25. Mr. R. J. McNeill Love, chairman of directors, said that the society had been able to help many of its members both by advice on the difficult questions which arose out of the Superannuation Regulations and by devising new policies to meet the altered conditions. Their widow's protection and pension protection policies had solved the problems of many doctors who were concerned with the lack of provision for their wives and children under the new Service. They had decided to abolish the war clause in all their policies. They had also decided to abolish extra premiums for residence overseas in any capacity, save in very exceptional circumstances. There was now no extra premium for those serving in H.M. Forces. These remarks applied only to life assurance policies, ut they had also made substantial concessions as regards sick- ss insurance for those who reside overseas. In approved ses, although the policy limited benefit to residence in the nited Kingdom, they were allowing full cover in other parts of the world, subject to reconsideration at the end of five years. A private limited company, the Medical Sickness Finance Corporation, Ltd. (see *Journal*, July 23, p. 239), had been *incorporated with a capital of £25,000 in £1 ordinary shares.* The corporation operated from the society's offices. The facilities were available not only for members of the society but for all medical and dental practitioners, and in approved cases those connected with the professions. Advances were made on cars and on medical and dental equipment, and it would be found that the rates of interest charged were far lower than those usually required by ordinary commercial companies.

COMING EVENTS

International Union of Nutritional Sciences

In connexion with meetings of the Committee of the International Union of Nutritional Sciences, to be held in Copenhagen on Sept. 12 and 14, some scientific sessions will be held, as well as visits to institutes near Copenhagen of interest to nutritionists, between Sept. 12 and 16 inclusive. Those interested are invited to communicate with Professor H. Dam, Biology Department, Polytechnic Institute, Ostervoldgade, 10 L II, Copenhagen, Denmark, or with Dr. Torben K. With, Rigshospitalet, Copenhagen, Denmark.

Bengué Memorial Lecture

Professor René Sand, Professor of Social Medicine in the University of Brussels, will deliver the Bengué Memorial Lecture at the Royal Institute of Public Health and Hygiene, 28, Portland Place, London, W., on Thursday, Sept. 15, at 3 p.m. His subject is "World Trends in the Teaching of Social Medicine and Public Health."

Symposium on Amino-acids and Protein Hydrolysates

The Food Group of the Society of Chemical Industry has arranged a symposium on amino-acids and protein hydrolysates to be held at Senate House (William Beveridge Hall), University of London, Bloomsbury, W.C., on Sept. 28, 29, and 30. The programme is as follows: Sept. 28, 6 p.m., opening address by Professor E. C. Dodds, F.R.S. Sept. 29, 10.30 a.m., Mr. K. Bailey, Ph.D., "Some Features of the Amino-acid Composition of Proteins"; Dr. A. Neuberger, "Properties of Proteins"; Mr. G. R. Tristram, Ph.D., "Amino-acid Analysis." 6 p.m., Mr. E. C. Barton-Wright, D.Sc., "The Microbiological Assay of Amino-acids"; Mr. R. L. M. Synge, "Chromatographic Methods in Amino-acid Analysis"; Mr. C. H. Lea, Ph.D., "The Role of Amino-acids in the Deterioration of Food—the Browning Reaction." Sept. 30, 10.30 a.m., Messrs. C. Ockrent, Ph.D., R. O. Atkinson, and C. Simons, Ph.D., "Methods for the Manufacture of Amino-acids"; Mr. S. M. Partridge, Ph.D., "Displacement Chromatography as a Preparative Method for Amino-acids." 2.30 p.m., Messrs. G. M. Dyson, Ph.D., and E. M. Bavin, B.Sc., "The Preparation of Protein Hydrolysates"; Mr. H. G. Rees, Ph.D., "Applications of Amino-acids and Protein Hydrolysates in the Food Industry." 6 p.m., Dr. D. P. Cuthbertson, "Amino-acids and Protein Hydrolysates in Human and Animal Nutrition." An open discussion will follow each session. The registration fee for participation in the whole symposium is 10s., payable to the Society of Chemical Industry, 56, Victoria Street, London, S.W.

Course in Public Health and Industrial Health

The Royal Institute of Public Health and Hygiene announces that the next course of instruction for the Certificate in Public Health and for the Diploma in Industrial Health (Part 1) will commence on Sept. 30. Full details may be obtained from the secretary of the Institute, 28, Portland Place, London, W.1.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Conway.—On July 19, 1949, at Glasgow, to Dr. Lilian I. Conway (née Donald), wife of Dr. Hugh Conway, M.R.C.P., a daughter.

Johnson.—On July 7, 1949, at Kuala Belait Hospital, Brunei, Borneo, to Betty Jane (née Powell), wife of Dr. A. W. Johnson, a son.

Nauth-Misir.—On July 25, 1949, at Oldchurch Hospital, Romford, Essex, to Iris (née Hall), wife of Dr. T. N. Nauth-Misir, M.B., M.R.C.P., D.C.H., a son—Nigel Isridutt.

Seward.—On July 10, 1949, at the Charlton Nursing Home, Plymouth, to Margaret Mary (née Vaughan), wife of F. W. R. Seward, M.R.C.S., L.R.C.P., of Redlands, Bridgetown, Totnes, Devon, a daughter—Suzanne Margaret Linda.

MARRIAGES

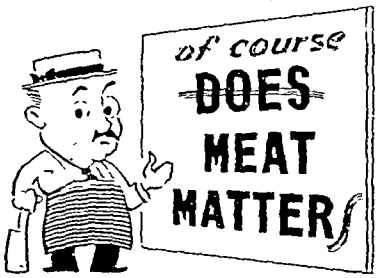
Evans—Mitchell.—On July 31, 1949, quietly, at the Church of the Ascension, Blackheath, Dr. Carlton John Evans, of Lewisham, to Dr. Alexa Mitchell, of New Cross.

Harris—Burr.—On August 2, 1949, in London, Nigel H. Harris, B.A., M.B., B.Chir., of Grimsby, Lincs, to Elizabeth Burr, of Hallingbury, Herts.

DEATHS

Butler.—On July 29, 1949, Hedley Ormonde Butler, M.B., B.Ch., late of Chiswick.

MacKenzie.—On July 25, 1949, at Croit Mhairi, Tain, Ross-shire, Colin MacKenzie, M.B., Ch.B.



O'Neill.—On July 27, 1949, at North Cheam, Surrey, William O'Neill, M.B., B.Ch., D.M.R.E., aged 57.

Rosser.—On July 25, 1949, Richard Picton Rosser, M.B., Ch.B., of 3, Royal Chase, Tunbridge Wells, Kent, formerly of Darlington.

Southey.—On July 21, 1949, at 111, Tonbridge Road, Maidstone, Herbert Watson Southey, M.R.C.S., L.R.C.P., aged 81.

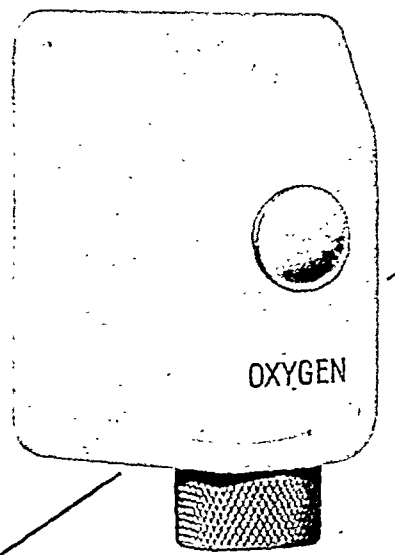
Wagstaff.—On July 25, 1949, at a nursing-home, Charles Bertrand Wagstaff, M.R.C.S., L.R.C.P., of 15, Huntly Road, Bournemouth.

Williamson.—On July 23, 1949, at Grimsby and District General Hospital, Jessie, the dearly loved wife of Dr. Joshua Williamson, of Cleethorpes, Lincolnshire, aged 71.

You can hear how much it matters by listening in the shopping queues!

Well, everyone's working hard, and the harder people work the more they hanker after good satisfying meals. And "a good satisfying meal" to most people means a meat meal. Nothing else (they feel) can give the same fine sensation of well-being. Nothing else (they think) can keep them in hard-working trim.

Of course medical experience shows that this is only subjectively true—that although most people are accustomed to *enjoy* meat, and miss it when they can't get it, other foods can supply, and, in fact do supply the amino-acids in which meat's nutritional value lies.



For patients requiring a generous protein intake, Bemax will be found an invaluable supplementary food. Its protein content is higher than that of most other common foods, and amino-acid analysis shows its protein to be more like that of 'animal' than 'vegetable' origin. Actually, weight for weight, Bemax supplies *more* protein than does lean beef, and comparison of essential amino-acid contents shows it to be of *equal protein value* with beef.

* * * * *

The recommended daily ounce of Bemax supplies in a week more protein than the meat ration (taken as steak). *This in addition to its well-known vitamin contents!*

VITAMINS LTD UPPER MALL LONDON W.6

MODERN HOSPITAL PLANNING

This small unit, neat and compact, is all that need be seen or heard of the oxygen supply to a hospital ward.

THE BRITISH OXYGEN COMPANY LTD

WEMBLEY MIDDLESEX • RUSHOLME MANCHESTER

Incorporating Coxeter & Son Ltd. and A. Charles King Ltd.

INCREASED PREVALENCE OF HYPERACIDITY

One legacy of war-time strain persists. It is evidenced by the number of patients exhibiting symptoms of gastro-intestinal disorder.

The same stress factors of overwork, hurried, irregular meals and the inability to relax completely still prevail.

In such instances, 'Milk of Magnesia' is invaluable in securing rapid control of discomfort. A colloidal suspension of magnesium hydroxide, it soothes the inflamed mucosa, and neutralizes the excess acid, without liberation of gas. Furthermore, its mild laxative action ensures removal of toxic waste products.

'Milk of Magnesia' may be prescribed with confidence equally in the mild case of dyspepsia or the acute ulcer stage where sustained alkaline treatment is essential.

'Milk of Magnesia' contains approximately 8.45% Magnesium Hydroxide in colloidal suspension.

". . . the ports of slumber open wide
To many a watchful night!"
II Henry IV, iv, 4.

In insomnia . . .

In 'Carbrital' capsules the rapid, but relatively brief, hypnotic action of pentobarbitone sodium is combined with the prolonged sedative effect of carbromal. In insomnia 'Carbrital' produces slumber simulating natural undisturbed sleep of adequate depth and duration, and patients awaken refreshed and alert.

'Carbrital' is also indicated as a general sedative in neurasthenia, etc., for pre-operative sedation, and routinely in minor operations.

'Carbrital'

Each 'Carbrital' capsule contains 1½ grains of pentobarbitone sodium and 4 grains of carbromal.

Available in bottles of 10, 25, *and* 250 *capsules.*

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Blood-Brain and Meningeal Barriers

Q.—*What is meant by the "blood-brain barrier," and in view of the rich capillary ramification present in the brain how does it interfere with the entry of antibiotics to the nerve cells? Also, what does the term "meningeal barrier" mean?*

A.—The blood-brain barrier is the physiological mechanism which determines which substances can pass from the blood to the brain parenchyma and in what concentration. Oxygen and glucose are examples of substances which cross the barrier readily, while the bile pigments circulating in the blood in obstructive jaundice are an example of those that cannot. Akin to, but distinct from, the blood-brain barrier is the blood-cerebrospinal-fluid or "meningeal" barrier. This determines which substances can pass from the blood to the cerebrospinal fluid.

The mode of action of neither the blood-brain nor the blood-cerebrospinal-fluid barrier is as yet fully understood. Experimental work with dyes, however, suggests that the electrical charge on the ionized molecule plays an important part. Thus certain basic dyes, bearing a negative charge, when injected into the blood stream will stain the cerebrospinal fluid but not the brain, while acid dyes, carrying a positive charge, will stain the brain but not the cerebrospinal fluid. This factor is probably more important than the actual size of the molecule.

Most of the work on antibiotics has been concerned with their ability to pass the blood-cerebrospinal-fluid or "meningeal" barrier. This ability has proved to be very variable. For example, sulphadiazine passes the barrier more readily than does sulphathiazole, while the threshold for both penicillin and streptomycin is extremely high. Again, active inflammation of the meninges tends to increase the permeability of the blood-cerebrospinal-fluid barrier, but in different degrees for different substances. Thus, in active meningitis the passage of arsenicals from blood to cerebrospinal fluid is slightly facilitated, that of streptomycin is considerably increased, while that of penicillin is not significantly affected. The ease with which antibiotics can cross the blood-brain barrier is technically much more difficult to estimate; there is accordingly very little accurate information available on this subject. It seems possible, however, that penicillin may enter brain tissue more readily than it enters the cerebrospinal fluid.

Transitory Retrobulbar Neuritis

Q.—*What may be the cause, apart from disseminated sclerosis, of a transitory attack of retrobulbar neuritis?*

A.—In cases of transitory retrobulbar neuritis the differential diagnosis is from functional disease, local pressure on the nerve, or a vascular lesion either local or intracranial. Various authors differ in ascribing causes for retrobulbar neuritis, one stating that nasal disease heads the list, another that focal sepsis is the main cause, and a third that disseminated sclerosis overshadows all others. It is important to remember that there is a natural tendency to spontaneous recovery, and so the application of any remedial measure may be followed by recovery, suggesting a wrong aetiology. A transitory retrobulbar neuritis may result from either a rapid spontaneous recovery or transitory activity of the causative factor. The usual causes of the condition may be given as disseminated sclerosis, alcohol and tobacco, diabetes, pernicious anaemia, syphilis, plumbism, post-partum haemorrhage, sepsis, inflammation of surrounding orbital tissue, disturbances in nutrition, pregnancy, and menstrual disorders. Some attempt has been made in this list to indicate the frequency of the causes, but this is not put forward as incontrovertible.

Deficiency of 11-Corticosteroids

Q.—*A woman suffering from Addison's disease appears to have a deficiency of the 11-corticosteroids, and perhaps the as yet not isolated group of adrenal hormones. In her case salt and water balance is easily upset, and she develops symptoms of potassium deficiency on low doses of cortical extract. Are the synthetic 11-corticosteroids yet available?*

A.—This clinical picture is not infrequently met with—that is, one in which hypoglycaemia and lack of well-being appear to be more important than the salt and water depletion. The pure 11-corticosteroids are not available as such. They are present in some degree in the usually obtainable cortical extracts, and they occur in much higher concentration in a relatively new lipid adrenal extract made in the U.S.A. but not yet commercially available in this country, probably because of currency exchange difficulties.

Fertility with Advancing Years

Q.—*Is there any basis for the belief that the fertility of woman decreases progressively after a certain age, usually placed in the region of 30? As ovulation occurs only once in each menstrual cycle, and as this normally continues to about 45 or later, one would expect the chances of conception to be the same throughout the years of normal menstruation.*

A.—Observations carried out among various races all go to show that fertility decreases progressively long before the menopause, and, moreover, it is not fully developed for some considerable time after puberty. In white women fertility is relatively low until the age of 17 or 18 years, reaches a maximum at 20 to 25 years, falls slowly up to the age of 35 years, and thereafter rapidly. Although such statements are based largely on a study of the marriage-conception interval at different ages, without allowance always being made for other factors which may be concerned, and although there are individual exceptions, they are generally accepted.

Contrary to the implication in the question, regular menstruation does not necessarily mean regular ovulation, and it seems likely that all women occasionally have anovular cycles. The frequency of this phenomenon remains uncertain, but it is common, if not the rule, during the years immediately after the menarche, and it occurs more often after the age of 40 than during the more fertile years. Sometimes it appears to be the cause of sterility in young women, and it is generally assumed to be the main cause of physiological low fertility at the extremes of reproductive life. Nevertheless, other factors may be concerned—alterations in the function of the cervix and the body of the uterus, the age of the husband, the decreased frequency of coitus with advancing years, etc. The subject of physiological infertility as it affects animals and the human being is dealt with by M. F. Ashley Montagu in *Adolescent Sterility* (1946, Illinois).

"Irritable Eyelids"

Q.—*A professional woman aged 44 has been suffering for over eight weeks from "irritable eyelids." The itching is particularly marked at night, but during the premenstrual period it is very intense even during the day. There is a history of other allergic manifestations and vasomotor disturbances. Calcium injections have proved ineffective; "benadryl" has given only occasional and temporary relief. Can you suggest further treatment? Is any hormonal therapy indicated, in view of the premenstrual exacerbations?*

A.—One would suggest in the first place a complete ophthalmological examination, as astigmatism, early presbyopia, and other eye conditions may sometimes cause this condition. If these are excluded, skin reactions to the common inhalants (pollens, house dust, feathers, orris root, and moulds) and to the common and seasonal foods should be tested as a guide to the possibility that the irritation is due to the atopic type of allergy. Contact dermatitis might also be considered. Hazen (*Arch. Derm. Syph.*, 1944, 49, 253), in a series of 36 cases of dermatitis confined to the eyelids, found the following to be offenders: nail lacquer, orange peel, carbon

paper, wave-setting lotion, hair dye, face powder, dog hair, cold cream, sulphur ointment, ammoniated mercury, and soap powder. Premenstrual exacerbations of allergic reactions are not unusual, and are presumably due to increased oedema of the tissues at this time. Hormonal therapy is in general disappointing, but stilboestrol is worth a trial. Symptomatically, one of the other antihistaminic drugs, such as "phenergan" ("3277 R.P.") or "anthisan" (pyranisamine maleate), might be worth trying.

Medical Treatment of Myopia

Q.—*Is there any evidence that calcium lactate and parathyroid extract are of use in preventing the progress of myopia in children? If so, what dosage should be given, and for how long should treatment be continued? Is the parathyroid extract likely to cause any glandular disturbance?*

A.—The medicinal treatment of myopia was in vogue several years ago but is not now much used. It would appear that the results in the past with calcium and parathyroid extract have not been encouraging. In these days chief reliance is placed on ordering a full correction at as early an age as possible. The glasses should be worn all day long.

Toxic Effects of "Diparcol"

Q.—*Are there any dangers associated with the administration of the new drug "diparcol" in the treatment of Parkinson's disease?*

A.—Toxic effects which have been noted with "diparcol" (diethylaminoethyl-N-thiodiphenylamine) are somnolence, a slight feeling of drunkenness, and sometimes, though rarely, severe vertigo. These call for a reduction, possibly only temporary, in the dosage of the drug. A more distressing complaint, again rare and a sign of overdosage, is a temporary or almost complete paralysis, but this passes off in a matter of an hour. The drug sometimes also produces a temporary aggravation of Parkinsonian symptoms. The French workers who introduced this drug reported a fatal case of agranulocytosis, but considered this to be due to other drugs used at the same time; nevertheless, an occasional check on the leucocyte count is probably desirable. In debilitated patients, if the drug is stopped suddenly some degree of "collapse" may occur, and for this reason its administration should always be tailed off gradually. The same applies to its substitution for any of the solanaceous alkaloids: the change-over should be gradual. The two may safely be given together for a time. *It is best to* follow accurately the gradually increasing scale of dosage recommended by the makers.

Pus Cells in Semen

Q.—*The semen of a man aged 36, married ten years but with no children, is coloured yellow; motile sperms are absent, but there are a number of pus cells. The colour change is only recent. There is no history of venereal disease or trauma, but six months ago the testicles ached continuously for three weeks. There are no other signs and symptoms and the urine is clear. What is the cause? What investigations do you advise, and is there any treatment?*

A.—An attempt must first be made to discover the source of the pus cells in the semen. These may come either from infection of the prostate or vesicles, or else from a low-grade infection of the seminiferous tubules themselves. To exclude the former, cultures should be made of the urine passed after prostatic and vesicular massage. If nothing is grown from this, the semen itself should be cultured and the infecting organisms identified. But it is quite likely that what have been regarded as pus cells are actually spermatocytes exfoliated from the tubules. The cause of this may be some systemic or constitutional departure from health, which may be discovered by a careful medical overhaul. If nothing is revealed, a biopsy should be carried out to discover the exact state of the testicle. The outlook is poor, but, should the biopsy specimen reveal healthy testicular tissue, an attempt may be made to stimulate spermatogenesis by injections of chorionic gonadotropin prepared from pregnant mare's serum.

NOTES AND COMMENTS

Vaccination.—Dr. F. W. A. FOSBERY (Bristol) writes: I beg a small amount of your space to comment on the practice of vaccination as done by too many qualified doctors. Vaccination is compulsory for entry into the U.S.A. Too often have I to treat badly swollen, septic arms, caused by bad technique. The method of choice is: (1) to cleanse the skin; (2) drop (by any means, even gravity) a small bead of vaccine lymph on the chosen site; (3) puncture the skin through the bead, and wipe off excess; (4) do not cover. This is all that is required to produce immunization and avoids the crippling, unnecessary secondary sepsis favoured by covering the site. The international certificate requires a notation of the "reaction" (and this is more important than the fact of vaccination for entry into the U.S.A.), and the wording of the certificate should be quite accurate—i.e., (1) reaction of immunity; (2) vaccinoid; or (3) typical primary vaccinia. The term "successfully vaccinated" merely means that a needle has been passed over the skin. A certificate of "no reaction" is a reflection on the powers of observation of the doctor who certifies it.

Deafness after Penicillin Injection.—Dr. JOHN S. MEIGHAN (Bridge of Weir, Renfrewshire) writes: I recently had a patient, a man in early middle age, who complained of transient deafness and faintness following the intramuscular injection of a half mega unit of the sodium salt penicillin dissolved in 1.5 ml. of apyrogenic water. Three subsequent injections had no such effect, but he was made to lie down immediately after them. I would be very interested to know if anyone else has had this experience.

Bee-stings.—Dr. ALFRED R. HARGREAVES (C.M.S. Hospital, Gaza, Palestine) writes: Having been a bee-keeper for nearly 50 years I was interested in the question and answer on bee-stings ("Any Questions?" June 11, p. 1061). I would like to add to your expert's advice by suggesting that the best way to remove the sting, which, by the way, is barbed, is to scrape it out with the edge of a pocket knife. To pick it out with the fingers would only squeeze more of the venom into the victim. I always keep my open pocket knife handy when manipulating them. For treatment of the sting itself I find a drop of honey on the spot is very effective. I can imagine that there is more to this than mere hypertonicity and osmosis.

Adrenaline and Blood Pressure.—Professor HENRY BARCROFT and Dr. H. KONZETT write from St. Thomas's Hospital, London, S.E.: In the answer in "Any Questions?" (July 9, p. 111) it is stated that isopropyl-*nor*-adrenaline ("aleudrin," "aludrin," "neo-epinine," "neodrenal") causes a fall of blood pressure even when injected intravenously. This is so in anaesthetized animals[1]; in man (unanaesthetized), however, it caused a rise in the systolic pressure and a fall in the diastolic without much change in the mean pressure.[2] *During inhalation* of therapeutic doses of isopropyl-*nor*-adrenaline the arterial blood pressure is usually unchanged. In the isolated perfused dog's lung, administration of isopropyl-*nor*-adrenaline by means of an inhaler caused a slight fall of pulmonary arterial pressure.[3] Whether this happens in man is not yet known.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 13 1949

SURVEY OF SICKNESS

The Registrar-General's return for the quarter ended March 31 publishes the results of investigations carried out by the Social Survey into the rates of sickness and of medical consultation, comparing the figures for part of 1946 and the whole of 1947 and 1948. The samples interviewed consisted of about 3,000 people aged 16 and over "so selected as to be representative of the adult population of England and Wales." A different sample is chosen each month. At the interview the person is asked about his or her health during the two previous calendar months, the number and nature of the illnesses and injuries he suffered, the number of days of incapacity they caused, and the number of times he consulted a doctor.

Table I shows monthly sickness rates in the form of numbers reporting some illness or injury in the month per 100 people interviewed. The rates are higher for those over 65 than for those under 65, and in both age groups are higher for women than for men.

TABLE I.—*Monthly Sickness Rates*

		16–64		65+		16+
		M	F	M	F	Persons
1946	October	65	74	78	87	72
	November	63	75	83	89	72
	December	67	75	82	89	73
1947	January	65	74	77	88	72
	February	65	71	80	86	70
	March	60	69	79	84	67
	April	55	67	81	85	65
	May	57	67	75	85	65
	June	54	64	73	87	62
	July	53	62	72	84	61
	August	53	62	72	84	61
	September	58	68	74	84	66
	October	62	71	81	87	70
	November	62	72	79	87	70
	December	62	72	78	89	70
1948	January	60	68	79	87	68

	March	58	69	77	84	66
	April	55	66	75	85	64
	May	55	67	73	84	64
	June	56	66	70	81	64
	July	55	67	74	84	64
	August	53	66	75	85	63
	September	57	69	77	84	66
	October	61	72	76	88	69
	November	64	73	78	88	71
	December	65	75	83	88	73

Monthly medical consultation rates are shown in Table II. These rates are the number of visits made in the month to or by a doctor per 100 people interviewed. The doctors include ophthalmologists and other specialists. The figures exclude attention whilst an in-patient in hospital, and dental attention. The rates are similar between men and women of the same age, but are considerably higher for the elderly than for younger adults. The consultations referred to are mainly between patients and their family doctors.

Changes in the rates since July, 1948, indicate how the Health Service has influenced adults in seeking medical advice, comparison being made between the same seasons of the years. A comparison for the quarter October–December, 1946, 1947, and 1948, is illustrated in the figure below.

TABLE II.—*Monthly Medical Consultation Rates*

		16–64		65+		16+
		M	F	M	F	Persons
1946	October	38	41	64	55	43
	November	40	42	62	61	44
	December	42	42	54	68	45
1947	January	48	45	63	79	50
	February	45	38	64	89	46
	March	40	41	68	73	45
	April	37	39	60	73	42
	May	33	38	61	60	39
	June	28	35	49	46	34
	July	32	35	64	48	37
	August	31	34	50	48	35
	September	32	33	44	46	34
	October	36	35	47	51	37
	November	37	48	39	72	45
	December	35	41	53	65	41
1948	January	36	39	71	59	42
	February	39	41	80	69	45
	March	41	42	73	61	45
	April	33	36	80	57	39
	May	34	35	59	62	39
	June	35	39	49	47	39
	July	32	39	58	73	40
	August	31	35	42	65	36
	September	29	41	43	52	37
	October	35	48	59	61	45
	November	42	44	64	81	47
	December	38	45	61	88	47

For the December quarter the consultation rate for all adults in 1948 increased by 12% over that for the December quarter, 1947, and by 5% over that for the same quarter of 1946 among men aged 16 to 64, though with little difference between the rates for the corresponding periods in the three years. Among

women the rate for the December quarter, 1948, was 12% and 10% higher respectively than for the December quarters, 1947 and 1946.

For elderly men the rate was 30% higher in the December quarter, 1948, than it was in that period of 1947, but only 2% higher than two years before. The rates for elderly women in the December quarter, 1948, were 22% higher than those in 1947, and 26% higher than those in 1946 in the same period.

The report comments that since this section of the population has on economic grounds been most prone to go without sufficient medical attention in the past, this increase under the new health service is not surprising.

HELP FOR WAR DISABLED

MINISTRY OF PENSIONS SERVICE

Though most of the hospitals in the country now come under the Ministry of Health, the Ministry of Pensions still retains its own hospitals, regional examination centres, appliance clinics, and limb service centres. It provides medical services specially for the war disabled—services that are additional to, but do not replace, those of the National Health Service.

The Minister of Pensions has recently written to all the war disabled for whom his department is responsible, informing them of the benefits available and asking them to make sure that they are getting all they are entitled to. He has also sent them a pamphlet giving advice on obtaining medical treatment, telling the pensioner that he should first consult the doctor with whom he is registered under the N.H.S. If the treatment needed exceeds what his own doctor can supply, the local office of the Ministry can help. The Minister hopes that doctors will establish contact as necessary with the regional commissioners of medical services of the Ministry, whose names and addresses are given below.

London (South)	Dr. T. Sheedy	Sanctuary Buildings, 20, Great Smith Street, London, S.W.1
London (North)	Dr. T. H. Sims	25, Gordon Street, London, W.C.1
Tunbridge Wells	Dr. J. H. T. Harrington	Forest Road, Hawkenbury, Tunbridge Wells
Bristol ..	Dr. W. A. Date	Government Buildings, Vassal Road, Fishponds, Bristol
Reading ..	Dr. S. Vatcher	Whiteknights Road, Wokingham Road, Earley, Reading
Cambridge ..	Dr. G. P. Thorold	Brooklands Avenue, Cambridge
Birmingham ..	Dr. W. L. Fulthorpe	Dalton House, 94, Corporation Street, Birmingham
Nottingham ..	Dr. T. M. Bellew	35, Carrington Street, Nottingham
Manchester ..	Dr. W. L. Nicholson	Sunlight House, Quay Street, Manchester, 3
Liverpool ..	Dr. G. S. Swan	Orleans House, Edmund Street, Liverpool, 3
Leeds	Dr. A. L. McCreery	Government Buildings, Lawnswood, Leeds, 6
Newcastle ..	Dr. J. W. James	81, St. Mary's Place, Newcastle-upon-Tyne, 1
Cardiff ..	Dr. J. W. Davies	Dumfries Place, Cardiff
Edinburgh ..	Dr. J. W. McCagie	17, Rothesay Place, Edinburgh
Glasgow ..	Dr. A. S. Henderson	134, Sauchiehall Street, Glasgow
Belfast ..	Dr. H. Emerson	Tyrone House, 13, Ormeau Avenue, Belfast
Dublin ..	Dr. G. S. Moran	24, Merrion Square, Dublin

TREATMENT OF MERCHANT SEAMEN IN PORT

The Ministry of Health has informed executive councils that their responsibilities under the National Health Service extend to arranging for all necessary medical treatment given to seamen on shore in their area, including vaccination and inoculation for whatever purpose required. Seamen, unless on the list of the doctor providing the treatment, will be entitled to apply to be treated as temporary residents. Where a ship, British or foreign, lies at a wharf or within a port area controlled by a port authority, a doctor on the list of the council may agree to treat cases on board, and if so the temporary resident arrangements apply there also. Services for merchant seamen have in the past been given by doctors employed by the Shipping Federation; most of those doctors are also engaged part-time in the provision of general medical services, and in so far as this is the case it is thought that they will be included on the medical lists of executive councils and will continue to provide the treatment under the National Health Service. A small number of doctors have, however, been employed whole-time by the Shipping Federation; their position is being separately considered. It may sometimes be necessary for a number of seamen to be vaccinated or inoculated together, and in these cases it would clearly not be appropriate for the doctor to be paid on the basis of the usual fees for temporary residents. Sessional fees for such cases will be arranged instead, and are under consideration. Examinations by Shipping Federation doctors to decide on a seaman's fitness to go to sea remain the responsibility of the Federation and no claim will be made on the council. The question whether the Central Practitioners Fund includes an adequate amount to cover the expense of treating foreign seamen is being discussed, and additional information will be issued by the Ministry later.

REPEAT PRESCRIPTIONS

The Minister of Health has decided that a doctor, in order to avoid unnecessary calls on his time, may give patients two or more prescriptions, or carbon copies of the same prescription (all bearing original signatures), dated at suitable intervals. The type of case referred to is when the doctor considers that the patient's treatment should continue for longer than the first supply of medicine will last, and does not think it necessary to see the patient again or for a considerable time. These arrangements apply also to dressings—e.g., for chronic patients.

This decision has been made in accordance with advice by the Standing Medical and Pharmaceutical Advisory Committees of the Central Health Services Council.

HEALTH SERVICE IN LIVERPOOL

Addressing the Liverpool Executive Council recently the chairman, Mr. A. J. Murnaghan, said that the number of persons on doctors' lists—namely, 795,000—was equal to the estimated population. These lists were inflated owing to some previously insured persons making fresh applications, and the registers were being examined to correct it. The amount paid to 344 doctors was, in round figures, £665,000, of which £5,000 was for maternity services.

There were 165 dentists, who dealt with 85,000 patients and had been paid £543,000. This sum would have been greater by £34,000 but for the restriction that any amounts over £400 per month were to be reduced by one-half for a period of six months.

So far as the Supplementary Ophthalmic Service was concerned the list included 28 ophthalmologists, 116 ophthalmic opticians, and 13 dispensing opticians. No fewer than 164,000 persons had had sight tests at a cost of £139,000, and the cost of glasses so far supplied was £224,000.

Eight doctors had been allowed to have a trainee assistant; 31 had been given a basic salary of £300, and one an inducement grant of £200. Twelve medical practices had become vacant during the year, and with one exception they had been filled with the concurrence of the Medical Practices Committee.

SICKNESS BENEFIT CERTIFICATES

LONGER INTERVALS

Draft regulations that came into operation on Aug. 4 allow medical certificates for sickness benefit to be given at longer intervals in cases of prolonged illness. Before that date a chronically sick person submitted special intermediate medical certificates at maximum intervals of eight weeks if he was not seeing his doctor for examination or treatment at more frequent intervals. One effect of these provisions was that a patient who had to see his doctor every week for a renewed prescription or an injection was obliged to submit weekly certificates although both the doctor and the patient might know that the illness was going to last a long time.

The new regulations extend the intervals from eight weeks to 13 weeks and enable these certificates to be given even though the sick person is being examined or treated by the doctor at more frequent intervals.

The regulations have been made provisionally pending the report on them by the National Insurance Advisory Committee. The committee will consider objections to them which are sent before Aug. 26 to the Secretary, National Insurance Advisory Committee, 6, Curzon Street, London, W.1.

HOSPITAL BOARD APPOINTMENTS

The Minister of Health has made the following appointments.

To Regional Hospital Boards

Oxford.—Professor T. POMFRET KILNER, in succession to Professor A. W. Ellis.

South-West Metropolitan.—Mr. R. Chick, in succession to the late Alderman Wooley.

Leeds.—Mr. Henry J. Bambridge, to be chairman.

To Boards of Governors of Teaching Hospitals

Charing Cross Hospital.—Miss Kathleen Proud, in succession to Sir Sydney Parks.

Eastman Dental Clinic.—Mr. C. F. BALLARD, L.D.S., and Mr. G. A. MORRANT, L.D.S. R.C.S., in succession to Miss R. Caseley and Mr. C. Endicott.

National Hospital for Nervous Diseases.—Dr. MACDONALD CRITCHLEY, in succession to Dr. J. Purdon Martin.

Hammersmith, West London, and St. Mark's Hospitals.—Dr. L. COMYNS, M.P., in succession to Mr. R. Poots.

Royal Free Hospital.—Miss E. Burton, in succession to Mrs. F. E. Cayford.

London Hospital.—Mr. S. F. Johnson, in succession to Mr. W. H. Butler.

Leeds United Hospitals.—Mr. H. J. Bambridge, in succession to the late Mr. J. E. Fattorini.

HEARD AT HEADQUARTERS

Charities Ball

The Charities Ball held by the Metropolitan Counties Branch in May was a great success. A cheque for £500 has been sent in, of which £150 is to go to the Dain Fund, £150 to the Sir Charles Hastings Fund, £100 to the Royal Medical Benevolent Fund, and £100 to the Medical Foundation of Epsom. All those who worked so hard to make the evening enjoyable for the guests and so successful for medical charities are to be congratulated, particularly Dr. J. W. McCarthy, who was chairman of the Ball Committee.

The Press and Harrogate

The Public Relations Officer of the Association has had an amusing tilt with the *New Statesman and Nation*, which had stated that the whole tenor of the Harrogate meeting was "so grossly distorted by some Right Wing papers that the B.M.A. had to send protests to the editors of two of them." Actually no protests at all were sent by the B.M.A. to any paper—Right Wing, Left Wing, or Middle Wing. The Press, as the Public Relations Officer points out, can safely be left to look after itself. A number of interesting sidelights were obtained at Harrogate on the way the Press does its work. One newspaper correspondent told us at the end of the week that he had sent out as many as 80 "stories" from the meeting. In obtaining his "stories" the pressman has his own technique. In one of the Sections a woman doctor read a highly technical paper, which, like the whole of the discussion, could have no interest for the popular press. But at one point she broke off to relate a personal experience. Immediately after the meeting she was tackled by pressmen with their intimidating notebooks, and the first question which one of them asked her—asked in so many words, without the slightest apology or hesitation—was, "How old are you?" Rather taken aback, instead of boxing the ears of an impertinent young puppy, she said that she was 36. When the reporter was remonstrated with afterwards by one who was offended by this method of approach, he said that inquiry into the exact age of any person concerned in a news item was now the rule, and he maintained that the method was preferable to giving a vague impression of "young" or "middle-aged." But the thing for a doctor to do if he is betrayed into making a remark at a public meeting which has any news value is to run away afterwards with all speed unless he is prepared to disclose his age, his habits, and his domestic circumstances. Incidentally, there used to be a rule forbidding admission of the lay press to Sections except Medical Sociology and the like which have a certain public interest.

Not So Much a Problem

At conference after conference on the care of the elderly we hear it discussed how old people are to be "dealt with"—an infuriating phrase. The people who talk in this way are very earnest and public-spirited, but it might be useful for them to hear the comments of those who are discussed. A much sounder note was struck at a conference on this subject the other day by Dr. C. A. Boucher, a medical officer of the Ministry of Health, when he said that, although it was customary to talk about the "problem of the aged," he was not at all sure that there was such a problem. There was a much greater danger, he said, that we might be creating a problem for ourselves by trying to do more for the aged than they wanted us to do for them. He reminded his audience that the old are independent people who want to keep their individuality, and, while they are grateful for help and guidance, they do not want to be extracted out of the general pool or to feel that they themselves are not contributing to that pool.

Questions Answered

Appointed Factory Doctor

Q.—*What are the duties, and by whom is the appointment made, of (a) Certifying Factory Surgeon, (b) Appointed Factory Doctor. I believe that (b) is the correct designation as stated in the N.H.S. Act, but have no means of checking this; it is, I take it, a new office.*

A.—It is not a new office. "Appointed Factory Doctor" is the new name given by the Factories Act, 1948, to the Examining Surgeon (formerly known as the Certifying Factory Surgeon). The appointments are made by the Chief Inspector of Factories, Ministry of Labour. The Appointed Factory Doctor carries out certain statutory medical examinations, including examinations of young persons (under 18) entering industry as to their fitness for employment, follow-up examinations of young persons, and periodic examinations of persons engaged in certain dangerous processes. His other duties include the investigation of and reporting on certain cases of gassing and industrial disease. He has no statutory duties under the National Insurance (Industrial Injuries) Act, 1946, but his services are used by the Ministry of National Insurance for the diagnosis of cases in which injury benefit is claimed under this Act.

The South Caernarvonshire Medical Society, which was established early in 1948, states in its first annual report that it has constantly pressed for (and will continue to do so) some provision towards heavy telephone costs, free postage on Health Service matters, adequate payment for treating temporary residents, a Government contribution towards the costs of surgery maintenance, and other improvements. Appeals have been made to the Minister of Health, the B.M.A., and other bodies, and the society has emphasized that the capitation fee must be satisfactory to general practitioners. Medical practitioners all over the country, it states, must unite in strong and definite action.

MEDICINE IN NIGERIA

REPORT ON PRIVATE PRACTICE

Under a commission appointed on July 24, 1948, Sir Sidney Phillipson was appointed "to review the present system relating to the private practice of medicine and surgery by officers of the Department of Medical Services (Nigeria), and in the light of that review to make recommendations regarding future policy and the most suitable means of giving effect thereto." The report has been published.[1]

Sir Sidney Phillipson found that Government medical officers recognized the need for a material change in present arrangements, though their views on how they should be changed differed widely. On Aug. 31, 1948, there were 200 officers in the Department in the higher professional grades, including dental officers and assistant medical officers. Of these, 50 were debarred from private practice and received no staff pay, 18 were debarred from private practice but received staff pay, 81 were allowed private practice, and 51 were temporarily allowed private practice by local dispensation.

There were two main divisions of private practice. The first comprises that system under which officers of the Department are allowed by their conditions of service to charge directly patients who do not come within the categories of patients for whom they are required by the terms of service to provide free medical attention.

Injection Practice

The second division is "injection" practice. This practice, "at one time very extensive in certain parts of Nigeria and still largely followed," consists in giving injections "more or less on demand, normally without clinical examination, to those who ask for them, a fee being recovered for each injection given."

He discusses injection practice in a separate part of the report. Many people in Southern Nigeria have great faith in the efficacy of injections for all human ills. This faith is said to have originated some 20 or so years ago when N.A.B. injections were used in the treatment of yaws. The remarkable effect of a single injection in clearing up the symptoms deeply impressed the people. Since then injection practice has enormously increased. Sir Sidney concludes that it is undesirable and should be regulated.

He recommends that injection practice should be brought under rigorous and comprehensive control for both Government medical officers and private practitioners. No injections should be given by Government medical officers on tour at points other than Government hospitals and dispensaries. Fees for injections should be paid into Government revenue if the injections are given at a Government institution, or into Native Administration revenue if they are given at a Native Administration institution with drugs supplied by the Native Administration. "All measures savouring of advertisement of injections shall be strictly forbidden."

Prescribed Scale of Fees

Among his recommendations on ordinary private practice conducted by Government medical officers he says that fees for professional services (including operations) rendered in public institutions should be in accordance with an officially prescribed scale. The scale should provide for adjusting fees according to the means of the patient, and it should be worked out in consultation with representatives of the unofficial private practitioners. Of the fees prescribed for certain non-routine operations performed within Government institutions 50% should be paid to the medical officers who performed them.

Government medical officers should be allowed the fees prescribed for consultations in respect of cases referred to them by unofficial private practitioners. These payments should be made from a special medical fund. The medical fund would be created from the fees for professional services rendered in public institutions.

[1]Government Printer, Lagos. Obtainable in England from the Crown Agents for the Colonies, 4, Millbank, London, S.W.1.

Health Insurance Scheme

He also recommends that some form of health insurance scheme should be studied in relation to large employers of labour. The scheme would provide for contributions by the firms and their employees. The employee would have the right to select his own private practitioner from a panel drawn up after consultation between the Government, the private practitioners, and the firms concerned.

GENERAL MEDICAL SERVICES COMMITTEE

At the meeting on July 28 of the General Medical Services Committee, part of which was reported in the *Supplement* of Aug. 6 (p. 74), certain questions relating to dispensing for temporary residents were referred to the Rural Practitioners Subcommittee.

The committee considered the treatment of seamen as temporary residents by doctors engaged in the Service. The Deputy Secretary reported on a meeting convened by the Ministry of Health at which representatives of the Shipping Federation were present. A point which arose concerned the temporary-resident fee in the case of persons in ships which port medical officers were required to visit. The visit sometimes necessitated a long boat journey. The Federation's representatives undertook to explore the possibility of settling the matter by an internal adjustment. The further question arose whether a doctor under his terms of service was required to visit a vessel at sea and, if so, at what distance out. The area of an executive council includes rivers, but wide estuaries and ships some distance from shore seem to open up new problems. A cognate question concerned boys in training on board ship and their status as temporary residents. Here, however, it was pointed out that they were a picked class, having undergone routine examination (which examination would be outside the terms of service), and that if any did fall ill they were likely immediately to be sent home or to hospital.

Liaison with Dentists

The British Dental Association had accepted the suggestion that there should be an exchange of observers on committees representing the common interests of general medical and dental practitioners. The committee appointed Dr. F. Gray as observer on the corresponding committee of the B.D.A.

Resolutions of A.R.M.

The committee examined the many resolutions of the recent Annual Representative Meeting which had been referred to it, and decided on appropriate action to be taken. A number of them were listed to be taken up with the Ministry of Health at the next meeting with the Ministry's officers. On the question of the resolution which was carried by the narrowest of majorities at Harrogate, declaring that a defendant doctor before a Medical Services Committee should be represented by a paid advocate or solicitor if he so desired, the general feeling of the committee was that in view of the narrow vote this question should be deferred until the next session and reconsidered in the light of experience, when the constitution of Medical Services Committees might also be considered. The chairman pointed out that one objection to paid legal advocacy which occurred to him was that the other side might retain a specialist lawyer who would go from place to place cross-examining with a certain facile skill in a way which might put an innocent practitioner in a difficulty.

The resolution protesting against the steady exclusion of general practitioners from work in hospitals was referred for immediate action, the chairman remarking that in contacts with practitioners from other countries it appeared that they were all associated with some hospital.

On the resolution supporting the principle that general practitioners should be able to order stock drugs on Service prescriptions, Dr. Jope said that the Ministry itself was anxious to introduce this on the ground of economy. Dispensing fees

had been fixed on the assumption that there would be 140 million prescriptions annually; in fact there had been 200 million.

Filling of Practice Vacancies

Dr. Howie Wood brought forward the unfortunate case of a doctor who had travelled a return journey of 500 miles on the strength of a letter from an executive council which suggested that he was the only candidate for a vacancy invited to attend. He had asked beforehand for information about accommodation should he be appointed to the practice, but received no reply, and on attendance at the interview he discovered that there was the most unsatisfactory and indeed untenable position with regard to accommodation, and withdrew his application. The practitioner whose retirement had created the vacancy had sold his house, from which the practice was conducted, and apparently the only hope of accommodation for the newcomer was a nursing-home shortly coming on to the market and not well placed in relation to the practice. He felt that applicants should be supplied with full information before being put to the trouble and expense of an interview.

The committee, while expressing sympathy with the practitioner concerned, felt that the case was wholly exceptional. It was explained that it arose owing to the illness of the clerk of the executive council and the misunderstanding of a deputy, and the committee decided to take no action.

NORTH WALES BRANCH CENTENARY

The North Wales Branch of the Association celebrated the centenary of its foundation on July 20, and Dr. Leslie Jones was elected president. In his address[1] he emphasized the enthusiasm with which the pioneers of medicine contributed to the foundation of the Branch. The early meetings had been attended by doctors who rode in forty miles on horseback.

The celebrations opened with a service at Bangor Cathedral, which was taken by the Bishop of Bangor.

Speaking at a dinner given in the evening Sir Henry Morris-Jones, M.P., said that Wales had made greater contributions to medicine than to any other profession. Rural practitioners in Wales were among the finest types of country doctors in the Kingdom. Dr. Leslie Jones said that the rural practitioner, though hard-worked, had many compensations. One was the intimate relationship between patient and doctor which did not exist in the towns. Colonel R. D. Briercliffe emphasized the need for a medical school at Bangor as well as a large up-to-date hospital. Professor G. I. Strachan, of the Welsh National School of Medicine, said he was in sympathy with the need for a better hospital and a medical school at Bangor, but they should remember that the question was a big one and delicate. He was afraid that much water would flow under the bridges before a medical school could be established at Bangor.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

[1] *North Wales Chronicle*, July 22.

The Minister of Health has decided that travelling and subsistence allowances of the two members appointed by the university to attend meetings of the local medical committee at which applications for training grants for assistants are considered may be regarded as administrative costs of executive councils.

Correspondence

Grading of Hospital Staff

SIR,—Your leading article (*Journal*, July 23, p. 220) rightly voices the widespread dissatisfaction that exists over the grading of specialists, but it also raises several other points of considerable moment to those of us in the depressed class of trainee specialist.

Your sympathy with those of registrar status is appreciated, but it is a little surprising that you single out for particular mention those who have been qualified for four or five years only. Such men even before the war, when their 'prentice period was not interrupted by a year and a half of National Service, could hardly have expected to find their way into consultant or specialist work at the age of 27 or 28. There must be a very much larger number of would-be specialists who graduated before the war or in its early years and who were in the Forces for five or six years, some of them attaining specialist status.

Those of us in this group were encouraged to specialize by the repeated forecasts of great expansion in specialist services under the N.H.S. and by the provision of Class III grants. We have been grateful for the latter, without which specialization for most of us would have been impossible, and (particularly that majority of our number who have hostages given to fortune in the shape of wife and family) have borne with comparative equanimity a necessarily straitened standard of living and a deepening furrow on the brows of our bank managers in the hope of eventually finding ourselves freed from financial anxieties and congenially employed in the work for which our training and laboriously acquired qualifications have fitted us.

We have been repeatedly advised to hang on until hospital establishments are settled, but are now left with the impression that few, if any, additional specialist posts are to be created. The proverbial, if unphysiological, cardiac emetic action of *hope deferred leaves us* wanly facing the question whether or not the time has come to cut our losses and enter general practice, in the role of assistants perforce, along with and under the same conditions as recent graduates (and at a very considerable financial disadvantage compared with our newly qualified dental colleagues). No sneer is intended at general practice, which has its own satisfactions, but a shotgun wedding is inevitably disquieting, even though the union prove a joyful one.

The hope expressed in your leading article that retiring general-practitioner consultants may be replaced by outstanding general practitioners from the district has caused immense surprise among trainee specialists of my acquaintance and has occasioned reflections on whether it is an inspired indication of B.M.A. policy. Is it tacitly indicated that the outstanding general practitioner chosen will relinquish his practice and undergo a period of intensive training before assuming his new responsibilities? It is felt that the technique and complexities of modern medicine and surgery as specialties are such that a direct transition from outstanding, and presumably very busy, general practitioners to consultants is hardly likely to be successful.

It would be greatly appreciated by all trainee specialists, I am sure, and would relieve their universal chronic anxiety state if information could be given about whether there is likely to be any significant increase in the present number of specialist posts, particularly as general physicians and surgeons, and, if so, if some rough indication could be given of what proportion of the existing triers are likely to succeed. It has been estimated that pre-war about one registrar or trainee in three or four eventually reached consultant status. The odds against would now appear to be considerably larger.—I am, etc.,

Edinburgh. W. A. L. MACFADYEN.

SIR,—"Qualified Consultant" (*Supplement*, July 16, p. 50) has put into words what I have felt for some time. The profession has been split into castes, with the teaching hospitals

loath to associate themselves with the non-teaching groups, and the consultants determined to keep apart from their lesser-graded brethren.

That this is so can be seen by the arbitrary way in which *all* the visiting staff in teaching hospitals were "unanimously" graded as consultants, irrespective of the fact that some were indulging in private general practice and N.H.S. general practice and some had no higher qualification, yet in the case of those on the less-exalted hospitals these three factors were vehemently stressed.

"Qualified Consultant" asks who has let us down. The answer is our own colleagues. The gradings were performed by members of our profession who, contrary to all expectations and to frequently stressed guarantees, reversed the Ministerial rulings and supported dead-end grades, and almost with enthusiasm demoted their colleagues and trampled on the lifelong devotion to a specialty which these down-graded—and to some this spells degraded—doctors had so unselfishly given, in most cases in a purely honorary capacity, prior to July, 1948.

Even local consultants advisory committees have excluded some of their colleagues, sometimes their senior colleagues, from participating in their present deliberations.

Don't you feel, Sir, that if those responsible for gradings had stood firm and unselfishly behind their colleagues and the committees referred to had refused to accept any contrary gradings, and the B.M.A. had staunchly defended and supported the principle of the "job determining the grade and the remuneration" the whole bitterness and shattering of ideals which this affair has caused would have been avoided, and many of those merrily at work now would carry on equally merrily in the future? Do you honestly think, Sir, that a down-graded man, *if* he does remain in the Service as such, would be happy knowing his ambitions have been crushed, and crushed by his fellow men?

To quote "Qualified Consultant's" last paragraph, "Never in the history of medicine in any country has such a situation been imposed by a Government on an honourable profession"; may I add, "And implemented by members of that profession themselves"?—I am, etc.,

"K."

SIR,—Although your leading article on the above subject (July 23, p. 220) casts a useful ray of light upon the subject, it is to be hoped that you will be able to elaborate one of its comments further. You say: "There would seem to be a case for the grade of S.H.M.O. in mental hospitals, tuberculosis sanatoria, and fever hospitals."

I personally find it a little difficult to stomach this discrimination. A substantial group of us, including not a few who served in the Forces during the war, and many of whom are married and have families, have laboured diligently and been at great pains to acquire higher qualifications appropriate to our specialties, or are at present conscientiously doing so. Would you have each of us accept it that because he has chosen psychiatry, tuberculosis, or infectious diseases he must ultimately expect lower professional status than would be the case if he specialized in dermatology, orthopaedics, or general medicine?

Your next sentence seems to imply that a child suffering from diphtheria is a less valuable life than is an older subject afflicted by cardiac decompensation, that an intelligent executive afflicted by an obsessional neurosis matters less than a (usually duller) individual the victim of gonorrhoea, or that a promising career threatened by tuberculous infection is less to be considered than his friend who is in the throes of a spinal caries. Else why is it suggested that the assistant in the fever hospital cannot be designated as a specialist, when presumably his equally well qualified colleague in general medicine, dermatology, orthopaedics, or anaesthetics presumably can?

I shall hand it to you, if you wish, that the specialist surgeon has a right to consideration above all other groups, although I gravely doubt the wisdom of any such distinction; but to relegate the practitioners of three specialties to subordinate status is, in the event, to degrade the specialties themselves. If the practitioner in one of these branches who aspires to the D.P.H., the M.R.C.P. or M.D., or the D.P.M. must accept lower status than the holder of M.R.C.P. or M.D. in general medicine, then he may as well save himself the trouble of the necessary study or else deny his services to the branch of medicine for which he is most fitted.

I hope that you will comment further, so as to clarify the position and to relieve psychiatry, etc., of any special stigma.—I am, etc.,

Leicester. DAVID T. MACLAY.

SIR,—Dr. Arthur S. Wigfield (*Supplement*, July 23, p. 58) complains of the shabby treatment of the specialty of venereology in Liverpool. Yet on his own figures Liverpool has been treated absolutely fairly, and received the only possible grading—if I understand the present basis of grading.

Unfortunately those responsible for grading seem to have fallen into the trap set by a too simple nomenclature.

When a doctor holds a whole-time appointment he is clearly a hospital doctor. When he is head of his department he is clearly the senior hospital doctor. Since he has a whole-time appointment he is not available for consultation for any few remaining valued private patients. He can, then, scarcely be a consultant, but is clearly senior hospital medical officer. Q.E.D.

The part-time man, who is available for consultation anywhere, unfortunately is not senior to his chief, so could not possibly be graded higher. Q.E.D.

When I was a schoolboy Q.E.D. meant "Quite Easily Done." I am afraid it will not be quite so easily undone. We shall need to define professional status as distinct from qualifications or appointments.—I am, etc.,

Crowthorne, Berks. H. D. FORBES FRASER.

SIR,—May I use your columns to make a plea on behalf of those specialists working in the tuberculosis service and particularly those in sanatoria?

By the large-scale use of the grades of S.H.M.O. and J.H.M.O., never envisaged by the Spens Committee but introduced by the Ministry of Health with the obvious intention of obtaining the services of specialists on the cheap, many doctors in the tuberculosis service find that they will be very much worse off than they were led to believe they would be when the Government announced their acceptance, in principle, of the recommendations of the Spens Committee.

My case is, I think, judging from the opinions expressed at a meeting held recently in this region, fairly typical of what is happening to doctors in the tuberculosis service.

I have been qualified nearly eight years and have been working whole-time in a sanatorium for almost four years, and I hold a higher degree obtained on the strength of my specialized experience. I have just been graded as a J.H.M.O., and this grading has been confirmed on appeal. I may therefore expect to receive a salary of £850 per annum rising to a maximum of £1,000. This compares with a salary of £1,200 in terms of 1939 money recommended by the Spens Committee for a Grade I potential specialist in his fourth year. But comparison of grades and salaries offered bear little relation in many cases to the recommendations of the Spens Committee, for their proposals, although accepted in principle by the Government, have been largely discarded by the Government in its search for cheap specialist services.

Much protest has been raised against the grade of S.H.M.O., but I feel that much more protest can fairly be raised against the grade of J.H.M.O. This grade is, I submit, entirely unnecessary, as all the practitioners placed in it could fairly be placed in one of the registrar grades and promoted to S.H.M.O. or consultant in due course, with the advantage that appointments in the registrar grade are limited in time in almost all cases, and promotion may be expected to follow in due course. On the other hand, the grade of J.H.M.O. appears to be a complete dead-end with little or no prospect of promotion, as it is reasonable to assume that appointments to the grade of S.H.M.O. and consultant will be made from the registrar groups. It thus seems highly probable that a practitioner in the J.H.M.O. grade is likely to stay in that low grade

indefinitely, for appointments in this grade do not appear to be limited by time.

In this region this grade appears to have been freely used in grading members of the staff of sanatoria, and its use can hardly be calculated to encourage practitioners to enter this branch of medicine; and those already in this field must consider whether or not they should change to a branch of medicine where their experience and capabilities will obtain higher recognition.—I am, etc.,

"J.H.M.O."

SIR,—From time to time in the past you have been good enough to allow me a little space to express my views on some clinical matters. In common with many other practitioners at this time my mind has turned from the patient to a consideration of what is happening to medicine and those who practise it. It is on this subject that I hope you will allow me some further space. I refer, particularly, to your leading article (*Journal*, July 23, p. 220) on the grading of specialists.

The policy of the B.M.A. appears to be to resist all attempts to make further additions to the grade of senior hospital medical officer. But then one goes on to read that those doctors working in "mental hospitals, tuberculosis sanatoria, and fever hospitals" are not generally thought to be on sufficiently specialist work to be graded as consultants.

My own specialty being psychiatry, I am unable to make any suggestions about tuberculosis sanatoria and fever hospitals. It would seem, however, that practitioners in other branches of medicine are even less enlightened than the general public when it comes to the growing front of psychiatry. I would like to point out that at present only a comparatively small proportion of psychiatric work is carried out outside mental hospitals or the mental health services run by mental hospitals. To relegate the majority of psychiatrists to a lower status must mean either that they are regarded by the rest of the profession as having less professional skill and experience, or, which is more likely, that the mental hospital is still regarded as the place for custodial care of the chronic insane. We know that there are many who would like to see this happen and would prefer early and recoverable psychiatric cases to be treated outside mental hospitals.

I am quite certain that this development would be a disaster for the mental health of the country and would result in the best psychiatrists in the profession being driven out of the mental health services.

It does not seem to be sufficiently realized that the practice of psychiatry requires a degree of devotion and a peculiar kind of skill scarcely to be found in any other branch of medicine. Perhaps this is why many doctors have worked unceasingly and uncomplainingly in the past in mental hospitals under poor conditions and on inadequate pay.

In future, when the desire for adequate pay and status is becoming a collective urge which few of us can resist, one can only look forward to progressive diminution of the numbers of those training in psychiatry, unless others in our own profession are prepared to give us their support. The lay Committees of Visitors to mental hospitals have, of recent years, accorded to recent advances in treatment some of the recognition which they deserve. The development of insulin treatment, the discovery of electric convulsion treatment, and the operation of prefrontal leucotomy have all arisen in mental hospitals. There are many who feel that, without being fanatical, E.C.T. ranks with penicillin as a medical development. These discoveries have been mostly made by younger men. Is it too much to ask that young psychiatrists who have contributed to their own specialty shall be graded as consultants at 32, as Spens anticipated? To put the question in another way: What is expected of the doctor of 32 in the way of qualifications and experience so that he can be graded as a consultant?

It is time, therefore, that our own colleagues, and in particular those on the Council of the B.M.A., gave some recognition and acknowledgment to this work, bearing in mind recent estimates that up to 30% of the population suffer from neurosis at some time or other during their lives.—I am, etc.,

Warlingham, Surrey. R. A. SANDISON.

Doctors and Midwives

SIR,—Dr. Thomas B. L. Bryan (*Supplement*, July 16, p. 51) surely overlooks two important points. One is that the British midwife has, over a long period of time, won for herself the position which the midwife in this district quite rightly claims as hers—namely, that all normal confinements should be undertaken by the midwife, and that a doctor should be called in only for emergencies. This position is supported by Acts of Parliament as well as by the agreement of most medical practitioners.

Secondly, if this position is reversed and the midwife merely becomes a maternity nurse, or the doctor's handmaid, not only will this be, in our opinion, to the detriment of the patient, since few medical men have the necessary time to spare to remain with the patient as long as does the midwife, but it will discourage well-qualified women from entering the profession. On all grounds, therefore, it would seem that Dr. Bryan's suggestion is a completely retrograde one.—I am, etc.,

London, S.E.1. J. ELISE GORDON, *Editor, Nursing Mirror.*

SIR,—Dr. Thomas B. L. Bryan (*Supplement*, July 16, p. 51) and one of the midwives in his district do not seem to be working in harmony, the bone of contention being whose is the responsibility for normal midwifery.

This antagonism between doctors and midwives is no new thing, and I cannot do better than quote from the historical section of the report of the Working Party on Midwives, which I commend to Dr. Bryan, in which it is written: "The obscene invective which professional men directed at female competitors during the nineteenth century is well matched by that which women midwives directed against male competitors in the eighteenth."

We may be more gentlemanly and ladylike nowadays, but the difficulty remains unless both sides can take the wide view. It is not in the patient's interest that either the midwife or the doctor should monopolize the case. They must work together as a team. For abnormal cases the doctor obviously must be in charge. For normal cases a satisfactory apportion of duties is that the midwife conducts the actual delivery and that the doctor, if he wishes to be present, supervises any analgesia or anaesthetic required.—I am, etc.,

Manchester. C. SCOTT RUSSELL.

The New Civil Servants

SIR,—Dr. William Morton (*Supplement*, July 16, p. 50) states that one of H.M. Inspectors of Taxes has stated that a whole-time specialist is a Civil Servant.

This is surely quite wrong, as I know for a fact that officials previously employed by a Government department had to resign from the Civil Service on accepting employment with the regional hospital board.—I am, etc.,

ARCH. R. MILLER.
Hon. Sec., Glasgow and West of Scot and Branch.

Manor House Hospital

SIR,—It was a little surprising to hear on Sunday, July 24, a broadcast appeal by Lord Uvedale on behalf of Manor House Hospital and especially to hear him say that "the restoration of the poor and crippled to health is an object worthy of sacrifice and effort." Perhaps Lord Uvedale will explain why, in view of its intimate association with the trade unions, this hospital scorns inclusion in the National Health Service, from which it could obtain all its needs, and prefers to rely for support on a method which the Labour Party believes to be unnecessary, undignified, and unworthy of a great nation.—I am, etc.,

Cambridge. FF. ROBERTS.

Domiciliary Midwifery Service

SIR,—The new statement on the domiciliary midwifery service (*Supplement*, Aug. 6, p. 74) has made a very tardy and unfortunate appearance. Unfortunate in this way: that when people

realized that they could book the doctor for their confinement—having, for financial reasons, had the district nurse before—they not unnaturally expected to have *all* the antenatal examinations, the doctor to be in attendance, at any rate during the second and third stages of labour, and to put in post-natal visits. And even though the fee is not over-generous one felt that it was only right to undertake these services, which one did.

Now one is supposed to say, "I'm sorry, Mrs. Blank, but you won't be having your pethidine and scopolamine, and your whiffs of chloroform at the end, which were such a boon to you before; and I shan't be coming near you for six weeks, unless Nurse sends for me."

I have no intention of letting down my patients—and my profession—in such a manner.—I am, etc.,

Aylesbury, Bucks. W. A. BELLAMY.

Regional Consultants and Specialists

SIR,—I should be grateful for the hospitality of your columns to announce that the Regional Hospitals' Consultants and Specialists Association has instituted associate membership of the association for the following classes of medical practitioners in the hospital service:

(1) Those who are graded as registrars by a regional board.
(2) Those who hold a post of registrar status, whether that post is recognized by a regional board or not.
(3) Those who, in the opinion of the council, are of similar status.

The membership fee is 10s. 6d., payable on joining and carrying associate membership until the termination of the calendar year next after the date of joining. Associate members will have representation on the regional committees of the association but will have no vote.

A list of the regional representatives from whom, in each region, further information should be sought by prospective associate members is as follows:

Newcastle: Mr. R. E. Jowett.
Leeds: Mr. Donald Watson, Mr. A. R. Lister, Mr. R. R. Simpson.
Sheffield: Mr. L. Dougal Callander, Dr. J. W. Brown, Dr. P. H. O'Donovan.
East Anglia: Mr. J. M. Ridley Thomas.
N.W. Metropolitan: Miss A. H. Baker, Mr. C. Hope Carlton, Mr. A. Clifford Morson, Mr. Harold Dodd.
N.E. Metropolitan: Dr. F. Murgatroyd, Mr. J. B. M. Green, Dr. R. B. Niven.
S.E. Metropolitan: Mr. J. R. H. Turton, Mr. I. Monro Robertson, Dr. H. A. Treble, Mr. T. Meyrick Thomas.
S.W. Metropolitan: Mr. Nigel Cridland, Mr. N. Ross Smith, Mr. H. S. Taylor-Young, Mr. G. N. Golden.
South-western: Mr. C. E. Kindersley, Mr. L. Henry, Mr. W. H. Bradbeer, Dr. F. D. M. Hocking.
Welsh (North): Dr. H. S. Bell.
Welsh (South): Dr. W. Esmond Rees.
Birmingham: Dr. A. I. Cheyne, Mr. B. G. Scholefield.
Manchester: Dr. F. M. Hilliard, Dr. Hugh Selbourne.
Liverpool: Mr. A. W. Holgate.

—I am, etc.,

45, Lincoln's Inn Fields, London, W.C.2. NIGEL CRIDLAND, Honorary Secretary, Regional Hospitals' Consultants and Specialists Association.

THE SURGERY OF PULMONARY STENOSIS*

BY

R. C. BROCK, M.S., F.R.C.S.

Thoracic Surgeon to Guy's Hospital; Surgeon to the Brompton Hospital

The relief by operation of certain forms of cyanotic congenital heart disease (*morbus caeruleus*), especially those associated with pulmonary stenosis, has aroused widespread interest during the last two or three years, and this seems a suitable time to review the present position. In addition to assessing the results and value of the usual operation for this condition (the Blalock–Taussig operation), a preliminary account will be given of an entirely new operation which has so far proved successful and which may offer certain great advantages.

Human and Clinical Problem of Congenital Pulmonary Stenosis

The problem of the "blue baby" has always been a tragic one in which the doctor has hitherto been powerless to offer relief either to the sufferer or to the distracted parents. Although the plight of these children has been well known, it is only since the prospect of relief by operation has been available that the incidence and full tragedy of the condition has really come to light: those of us to whom these patients are brought for advice have been almost overwhelmed by the numbers and have been very impressed by the large amount of suffering and human misery that has been revealed. Many of these children have been almost hidden away in all parts of the country, not through any deliberate policy of concealment, but because many are necessarily, from their disability, confined to the house or to their room for the whole or the greater part of their lives. A few are able to get about out of doors moderately well under favourable conditions; some can manage to walk a short distance (10–100 yards); a number more must be wheeled in a "pram" or carried by their parents if they are to leave the house at all.

In extreme cases the child is very blue and dyspnoeic even while sitting or lying in bed and cannot move about at all; we have seen children as old as 6 years who have never walked. Some have been able to get about in a restricted fashion for a few years, and with the steady increase in their disability they finally become completely immobilized.

The strain on the parents and on the family life is considerable. The mother can rarely if ever leave the child, who not only occupies most of her attention but may give rise to periods of intense anxiety if, as often happens, it is subject to attacks of loss of consciousness and deep cyanosis and distress in which it appears to be near to death, or may indeed die. The burden on the mother is so great that she may abandon any idea of having more children, a situation that only heightens the tragedy when the blue child eventually dies. It is worthy of remark that the father always accompanies the mother when the child is brought for consultation; much of the carrying about of the child falls on the father, and it is in any case quite impossible for him not to be intimately involved in the management and anxiety of the grave family and domestic problem that the disabled child constitutes.

The more severely afflicted children die young; the mortality in the first few years of life is high. A number of children reach the early or even the late "teens," but usually with increasing disability. It often happens that a bright or intelligent boy or girl who has done well at school and even won scholarships becomes increasingly handicapped by the physical disability that prevents the fulfilment of what might otherwise be a promising and useful career. Only few patients are seen in the twenties who are able to carry out any useful occupation or employment.

The prognosis is poor, and this is strikingly shown by an analysis of the age of patients with cyanotic heart disease who have attended the congenital heart clinic at Guy's Hospital, which is under the care of Dr. Maurice Campbell. An analysis of the age incidence in 340 patients seen by Dr. Campbell over a period of some 15 months shows a rapid falling off which admits of no other general conclusion than that the prognosis is bad and becomes worse as the years pass. Campbell sums it up by stating that only one in two children is likely to survive till the age of 7 years; only one in four is likely to reach the age of 14, and less than one in 10 will reach 21. Moreover, 24 of these patients died while awaiting admission to hospital. These observations of Campbell's not only are of value to us in assessing the gravity and prognosis of the disease, but are also of assistance to the parent in making their difficult decision whether to agree to submit their child to the dangers of an operation.

The Place of Surgery

Although operation on these cases carries a considerable risk, the risk is in most cases far less than that of leaving the condition untreated. Moreover, operation alone offers a prospect of relief, and, as will be shown later in a discussion of the results, it offers a very good chance of striking and dramatic relief. It is now fair to say that surgery has fully justified itself by its results.

It is scarcely necessary to emphasize that operation in these cases is both difficult and dangerous. It is a type of surgery that is not for the lone operator. The problems involved are so numerous and complex that teamwork is essential if good results are to be obtained. It is not enough for the surgeon to acquaint himself merely

*The Alexander Simpson-Smith Lecture, delivered at the Medical Society of London on June 15.

with the technical details of vascular anastomosis and to think that he can then embark upon operations with safety and success. Team-work is of course essential in the operating theatre, where in addition to the surgical and nursing assistants the anaesthetist plays a part of fundamental importance which deserves a special tribute. Rink, Helliwell, and Hutton (1948) have recently published an account of their anaesthetic experiences.

Even more important, however, than team-work in the theatre is team-work before the operation, for much must be done in the diagnosis and selection of the correct cases for operation. Although it is almost a fashion to-day to speak of the need for team-work, it is difficult to overemphasize the need for it in the problem before us. Close co-operation with a cardiologist is self-evident; good radiology is essential, and we are fortunate at Guy's Hospital in having the valuable and whole-hearted co-operation of Dr. T. Hills in this; the physiologist and clinical research worker can contribute much in the study and application of the various tests and investigations of respiratory and circulatory efficiency; the anatomist and the pathologist are also valuable helpers. At Guy's Hospital there is a body of some 15 people actively engaged in the management of these cases, and all play their part in the efficiency and success of the service.

DIAGNOSIS AND METHODS OF INVESTIGATION

Until recently there was little general interest in the differential diagnosis of cyanotic heart disease, although a few enthusiasts have made invaluable studies and presentations of these cases. Until the advent of surgery great accuracy in diagnosis was rather an academic refinement of interest to the occasional clinician, as to the pathologist. Once the possibility of relief by operation arises it becomes essential to make the diagnosis as complete as possible before operation so as to avoid the hopeless case and to recognize the ones that can be helped. Careful clinical assessment, aided by routine radiography, is clearly of first importance, and for complete accounts of the clinical presentation it is best to consult the book by Helen Taussig (1947) or the comprehensive article by Campbell (1948). To arrive at a more exact diagnosis, especially in the very difficult cases, it is necessary to use cardiac catheterization and angiocardiography, both of which afford very valuable information.

The Blalock–Taussig Postulate

In considering a case for surgery it is of fundamental importance to realize what one seeks to achieve by operation. Blalock and Taussig (1945) have pointed out that the cyanosis is due to two things—namely, mixing of venous and arterial blood and an inadequate supply of blood to the lungs. The most important element of their contribution is the conception of the part played by the second feature—an inadequate pulmonary blood flow. As a result of this they postulated that the cyanosis and disability could be relieved by improving the blood supply to the lungs by anastomosing a systemic artery to a pulmonary artery. The proof of the correctness of their postulate lies in the good results of their operation: cyanosis is often completely relieved and is always greatly lessened when a satisfactory anastomosis is possible; the disability is also greatly relieved. As the venous-arterial shunt persists it may be impossible, except in the slighter cases, to relieve the cyanosis completely, at any rate after exercise.

It follows from this that the most important matter to be considered in the assessment of a case is in regard to the pulmonary blood flow; we must try to determine whether this is decreased or not.

Radiography and Radioscopy

Radiography and radioscopy are of first importance, for by their use it is possible at once to exclude those cases in which there is evidence of a plentiful or excessive blood flow to the lungs as shown by the degree of vascularity of the lung fields and visible pulsation of the pulmonary arteries. Atrial septal defect and perhaps Eisenmenger's complex are the common examples of this; transposition of the great vessels may present a similar picture.

In contrast, a typical case of Fallot's tetralogy has clear lung fields due to poor vascularity, and there is no visible pulsation in the hilar vessels. Careful radioscopy should give the necessary information, although in a doubtful case a direct reading of the pressure in the pulmonary artery will be decisive. This can be done during cardiac catheterization.

Cardiac Catheterization

A catheter passed along a vein into the right atrium can also be manipulated into the right ventricle and thence into the pulmonary artery and into its right and left branches. If septal defects are present the catheter may pass into the left atrium and then into a pulmonary vein, or from the right ventricle into the aorta (when the aorta is overriding). Pressure readings are taken in the various positions of the catheter, and also blood samples for estimating the oxygen content. In this way a great deal of valuable information is obtained. For instance, in pulmonary stenosis the pressure in the right ventricle is raised but that in the pulmonary artery is very low. As mentioned above, in Eisenmenger's complex the pulmonary arterial pressure will be high. By noting the exact level at which the drop in pulmonary blood pressure occurs it may be possible to obtain evidence concerning the site of the pulmonary stenosis—for example, whether it is valvular or infundibular.

The information afforded by cardiac catheterization is essentially complementary to other investigations and especially to angiocardiography.

Angiocardiography

This examination is of great value, and our policy at Guy's is to use it on all patients unless there is a grave contraindication. For instance, it is occasionally waived in the case of a small child who has severe cyanosis and in whom it is felt that the examination involves a considerable extra risk. Otherwise we feel that, quite apart from the diagnostic value of the test, the anatomical information it affords the surgeon is indispensable and of a character that is otherwise revealed only by thoracotomy.

It is easy, by angiocardiograms, to demonstrate the presence of a right-to-left shunt, because the aorta and its branches may be opacified after two to three seconds, simultaneously with the pulmonary arteries. Indeed, when there is a large shunt and a severe degree of pulmonary stenosis most of the contrast medium passes rapidly into the systemic circulation and so little enters the pulmonary circulation that the pulmonary arteries may be poorly shown.

By studying the anatomical arrangement of the great vessels the surgeon can form an idea whether they are likely to be suitable for making an anastomosis. It may, for instance, be shown that the aorta is very high and the subclavian artery so short that it could not be brought

down to meet the pulmonary artery; in such a case the surgeon would know that he had to use the aorta itself for the anastomosis (Potts's operation: Potts *et al.*, 1946). It is also valuable to know if both pulmonary arteries are present or whether one is absent or so small as to be useless. Conversely, if there is no deficiency of the pulmonary circulation, or even an excessive blood supply, this also will be revealed by the angiocardiograms.

SURGICAL METHODS

Having satisfied the first postulates—namely, that there are a deficient blood supply to the lungs, a pulmonary artery to receive the blood, and a suitable systemic artery to provide it—it is necessary to consider the most suitable age for operation and the most suitable type of procedure.

Blalock does not recommend operation before the age of 2 years unless the patient's condition is so grave that he is unlikely to survive long without it. The drawback to operating on young children is that the vessels may be too small to allow an efficient anastomosis to be made, or the anastomosis may cease to be adequate as the child grows up. Our policy at Guy's has been not to operate much before the age of 5 years unless for special reasons. This is partly because we feel that the older children on our waiting-list cannot with safety wait as long as most of the younger children can. The youngest child in our series was aged 2 years 11 months. Blalock also prefers not to operate on a patient over 20 years of age if possible. With this we strongly agree, for in these older patients the operative risks are far greater. The oldest patient we have operated on successfully was aged 29 years.

Certain general technical features of the operation need brief discussion, and for a fuller consideration I would advise reference to the article by Baker, Brock, Campbell, and Suzman (1949). Most of the points raised introduce important practical problems that should concern the surgeon undertaking this work.

Blalock's Operation or the Potts Modification

The Potts-Smith modification of aortic-pulmonary anastomosis has attracted enough attention to make it desirable to discuss its advantages and disadvantages first. It does not introduce a new principle, but is a technical modification based upon the original principles laid down by Blalock and Taussig. They postulated that certain cases of cyanotic congenital heart disease in which pulmonary stenosis existed could be improved by anastomosing a systemic artery to a pulmonary artery in order to increase the blood flow to the lungs, and in their preliminary discussions mentioned the use of the aorta as a possibility in place of one of its branches. It remained for Potts and his colleagues to introduce the ingenious clamp that made this possible. There has been a tendency on the part of a number of surgeons to use the Potts operation because it seems to be quicker and easier than the Blalock operation. It is true that Potts's operation may be preferable in a small child in whom the aortic branches are too small, or indeed in any patient in whom they are too small or too short. Moreover, it is possible to vary the size of the stoma at will. On the other hand, if it is possible to use the subclavian artery to make an effective anastomosis it would appear to be unjustifiable to choose deliberately to use the aorta instead. It cannot be good surgery to interfere with a structure of the importance of the aorta if it can be avoided. If any mishap occurs while the subclavian artery is being used it should be possible to control the situation by ligating the artery. If trouble occurs when the aorta is used it may not be possible to retrieve the situation.

There would seem to be a very real danger in the size of the stoma that is made when aortic-pulmonary anastomosis is used; if it is made too large a great extra strain is thrown on the heart. Acute pulmonary oedema may appear soon after the operation, or congestive heart failure may supervene later. I have already seen one case of severe congestive heart failure after the operation.

The great advantage of the Potts operation lies in those cases in which the subclavian artery is too small or too short and in which it has been suggested that the carotid or innominate artery should be used. The use of the aorta avoids interfering with these vessels, and thus spares the patient the greatly increased mortality (33%) and also the danger of severe paralysis from cerebral ischaemia. The use of the carotid or innominate artery is no longer justified in view of the high mortality and morbidity that have occurred.

Antero-lateral or Postero-lateral Incision

Blalock's practice of using the antero-lateral intercostal incision was followed almost exclusively in our first 50 cases, but has been departed from since then. In a very ill patient the antero-lateral approach may throw a smaller strain on the lungs and circulation than a postero-lateral. In general, however, the exposure provided by the antero-lateral intercostal incision may be rather cramped, and if the ribs are awkwardly shaped so as to make a high narrow chest the difficulties of dissection and ligation of the highest branches of the subclavian artery may be extreme. In such cases the exposure commits one to a set of circumstances that really constitutes faulty surgery.

My present practice is to use the antero-lateral approach only in those cases in which it may be necessary to operate upon the right ventricle itself. For all other cases a postero-lateral incision is used, with resection of the whole length of the fourth rib from transverse process to costal cartilage. By resecting a rib instead of incising the intercostal space there is much less bleeding at the time and less risk of oozing afterwards; post-operative pain is also lessened by avoiding the need for pericostal sutures. The exposure afforded by the long postero-lateral approach is a great advantage and allows a much more easy, rapid, and safe exposure of the vessels, and inspires the surgeon with much greater confidence that he has more complete control of the situation. The performance of the actual anastomosis is rather easier than from the front. Moreover, the postero-lateral incision allows use of either the subclavian artery or the aorta according to the conditions found. I have even, on one occasion, performed a direct operation on the right ventricle through a postero-lateral incision, but it is unusual to be able to do this with ease and safety; an anterior incision is preferable.

Right or Left Side

Blalock's earlier recommendation was to use the side opposite to the aortic arch in all but adults or patients in the later teens—that is, when the aorta is left-sided a right-sided incision should be made. This is in order to use the subclavian artery as it arises from the innominate artery; when turned down it forms an easy T-junction with the parent trunk, whereas if the subclavian artery is used as it arises from the aorta it may be kinked and flattened. In his latest paper Blalock (1948) states that he uses the right side (when the aorta is left-sided) in all patients between the ages of 2 and 12, but prefers the left approach in children under 2 and in patients over 12 who have attained

most of their growth or who are more than 5 feet (1.52 metres) in height.

After using the right-sided approach in nearly 50 cases I have abandoned it except in exceptional circumstances. In spite of increased familiarity and experience with the operation the dissection of the systemic artery on the right side may be extremely difficult, not a little dangerous, and certainly very exacting; especially so when the superior vena cava is large and dilated. If the innominate artery branches high up, the subclavian may be too short to reach the pulmonary artery; hence an anastomosis is possible only if the carotid artery is divided or the innominate artery is used. As already mentioned, this is no longer considered justifiable.

Another disadvantage of the right-sided approach is that it does not permit a proper examination of the heart and origin of the pulmonary artery and aorta in order to make as complete a diagnosis as possible. When the left side is used for the approach a very thorough examination can be made if the pericardium is opened.

In no case that I have so far done from the left side has the subclavian artery been so kinked or flattened that it jeopardizes the efficiency of the anastomosis. In any case in which the artery is found to be too short to use without tension, kinking, and flattening I either employ direct end-to-end anastomosis between the subclavian artery and the pulmonary artery or use the Potts operation of aortic-pulmonary anastomosis.

Post-operative Haemorrhage

We have found that there is a great tendency for bleeding to occur into the chest after operation in older patients who are severely cyanosed and polycythaemic and in younger patients with complete pulmonary atresia who have been submitted to exploration. This tendency is extremely dangerous, and severe bleeding occurs even after every care has been taken with haemostasis. The patients may appear to be progressing satisfactorily, and then collapse and die within a few minutes. The condition is insidious and rapid in its development. The best safeguard is the use of an intercostal drain which enables the bleeding to be recognized early and spares the patient the cumulative mechanical effects of the haemothorax. Even frequent examinations and radiography may not prevent rapid deterioration, especially during the night hours.

In the average young patient we have not, until recently, used a drainage-tube, because usually one or two aspirations are all that is needed and often aspiration is never wanted. However, our 99th patient, a boy of 7 years in whom operation was straightforward, died suddenly six hours later from the same cause; we therefore now make it a rule to drain every case.

These operations can be difficult and very exacting, demanding all one's patience, skill, and endurance; they may be made more anxious by deterioration of the patient's general condition. Nevertheless, we have found that it is best to press on quietly even when things seem almost desperate, and not to give up until it becomes quite clear that success is impossible. This applies not only to anatomical difficulties but to physiological ones as well. On several occasions the anaesthetist has reported the patient's condition as very grave, and the temptation to abandon the operation has been great. In almost all of these cases continuance with the operation after a short wait has been rewarded by final success.

The most striking example of the soundness of this policy came in the case of a very ill child of 5, who was deeply cyanosed, with severe recurrent pain in the chest even when resting in bed; she was incapable of any activity at all. During induction of anaesthesia her breathing stopped, and her heart also. The heart's action was restored after intracardiac injection of adrenaline. Spontaneous respiration did not return for over 40 minutes. Her condition was of course desperate. At the end of an hour her condition had begun to improve and it was decided to proceed with the operation. This was completed with success. The child made an excellent recovery and has continued to do well; she walks and runs about easily, a thing she was quite unable to do before.

Results

In his latest paper Blalock (1948) reports 610 cases treated by operation in which the overall mortality was 17%. The mortality ranged from 9% when the subclavian artery was used to 33% with the carotid or innominate. In the first 50 cases from Guy's (Baker, Brock, Campbell, and Suzman, 1949) seven deaths occurred, a mortality of 14%. The total number of cases in which the Blalock or Potts operation has been done or attempted at Guy's is now 83, and 13 of these patients died—a mortality of 15.5%. Among these 83 were many severely ill patients who were very poor risks; also included were a number in the late teens and the twenties.

Blalock states that the result was excellent in about 75% of his cases. The first 50 of our cases have been carefully followed and assessed by Campbell, who states that, in addition to the seven who died, in three there was no improvement and in four the result was only "fair." "This leaves 33 (66%) in which the result was almost perfect. The patients' capacity was enormously increased, up to walking several miles instead of a few hundred yards, or getting about all day instead of being an invalid mainly in the house. To the parents the improvement seemed almost miraculous."

The results in the good cases are indeed strikingly dramatic; in addition to the banishment of disability the cyanosis is usually changed to a good normal pink, although in some a mild cyanosis remains or can be noticed after exercise. It should be realized that the right-to-left shunt persists, and so it is not surprising that some degree of cyanosis may remain in the more severe cases, especially after exercise.

It would be possible to cite case after case of really dramatic improvement in the amount of activity possible. A typical case may be mentioned of a boy of 14 years who could walk only some 20 yards before becoming distressed and squatting down. Within a few months of operation he was able to walk several miles, could ride a horse, was learning to ride a motor-cycle, and is hoping to become a dirt-track rider.

It is a regular and rather heartening experience to receive letters from parents who state that they feel they must write and say what a joy and relief it is for them to watch their child setting off happily to school or playing with other children without distress, whereas before the operation such activities were quite impossible. In not a few cases a steady deterioration with increasingly frequent attacks of deep cyanosis and unconsciousness and the probability of death within a few months has been changed for apparent good health with no cyanosis or disability and complete cessation of the alarming attacks.

DIRECT ATTACK UPON THE STENOSIS

Although the Blalock-Taussig operation is brilliant in its conception and results, it has certain possible disadvantages, at any rate in theory. It is, in effect, a short-circuiting operation in which an obstruction is by-passed,

and in this respect is comparable in the soundness of its conception and the excellence of its results to the other classic short-circuiting operations in surgery such as gastro-jejunostomy for pyloric obstruction.

It differs from these operations, however, in that by creating an arteriovenous leak it actually imposes a new burden upon the body; in effect it gives the patient an artificial ductus arteriosus, a condition which, when it occurs naturally, we prefer to treat by operative closure.

On the other hand, there can be little doubt that in many cases this is the lesser of two evils, and, as Blalock and Taussig themselves say, there is no justification for letting a patient suffer and die from anoxaemia to-day just because he may develop trouble from his artificial ductus arteriosus in later years. Moreover, they suggest that in the presence of the interventricular septal defect and the overriding aorta the arteriovenous leak may not have the same significance as in an otherwise normal heart.

Whatever the answer to that question is, and time alone can tell, it is certain that surgery is not static, and that we must try to assess the feasibility and efficacy of direct operations upon the pulmonary stenosis in an attempt to relieve it. When one contemplates the small hole through which all the blood to the lungs must pass, whether the obstruction be at the pulmonary valves or lower down, it seems as if surgery should be able to offer relief to this mechanical obstruction.

Valvular Stenosis

In its simplest form the pulmonary stenosis may consist of a pure valvular stenosis with no interventricular septal defect, a condition that can be recognized clinically and can be confirmed by appropriate investigations. In most of these cases cyanosis is absent or slight in early life and appears later, usually during the teens; this is probably due to the effects of an increasing obstruction which in the presence of a patent foramen ovale causes a right-to-left atrial shunt to develop. In this type of stenosis it is certain that Blalock's operation is wrong, because it merely imposes an extra strain on the left ventricle and does nothing to relieve the strain on the right ventricle.

In a certain number of cases of Fallot's tetralogy (the exact proportion as yet being unassessed) the stenosis is also valvular in type.

The correct treatment for this condition is relief of the valvular obstruction by valvulotomy, an operation which I recorded a year ago (Brock, 1948) and which I have performed with success in five cases. In one of these not enough time has elapsed to assess the final result, although so far it would appear to be good; in two the result is moderately satisfactory and in two it is excellent. The valve is divided by inserting a special valvulotome through the wall of the right ventricle and passing it up into the pulmonary artery; haemorrhage from the heart is controlled by two rows of interlocking mattress sutures.

The actual valvulotomy is formidable, perhaps alarmingly so, but is not technically very difficult. The difficulties in the way of successful operation lie in the liability of the heart to fail quite suddenly soon after the chest is opened or as soon as it is touched. This is probably directly due to the extremely small size of the pulmonary outlet; while the heart is beating efficiently the circulation is maintained, after a fashion, but as soon as any fall in peripheral pressure occurs, with a corresponding fall in cardiac output, too little blood passes through the pinhole valve orifice to maintain the circulation. The coronary circulation suffers; the heart's action deteriorates further and soon ceases altogether.

Pulmonary valvulotomy was attempted in 10 cases, but in three the heart failed soon after the chest was opened and all three patients died. In the last of these three, as it was clear that the heart was making no response to all efforts at resuscitation, valvulotomy was performed in order to relieve the strain on the right ventricle and to enable blood to pass to the lungs. The effect was dramatic, for the heart at once revived and its powerful action was fully restored. Unfortunately the circulation had been arrested too long for the brain to have escaped injury, and, although the blood pressure was well maintained, death occurred six hours later from cerebral damage. From my experience with these three cases I am convinced that when a pulmonary valvulotomy is planned one must be prepared for the heart to fail soon after it is exposed, and if this occurs it is essential to perform valvulotomy *at once* and then to concentrate on reviving the heart; for unless this is done the heart is not likely to respond at all, or not before fatal cerebral damage has occurred.

Of the remaining two deaths, one occurred on the table from heart failure after the valve had been divided, but it was a badly chosen case of a woman in the twenties with a rigid calcified valve; the other patient (a woman aged 27) died from a haemothorax some hours after operation.

One of the patients in whom the result is classed as excellent is one of the three cases previously reported (Brock, 1948; Case H 107, Case 2). This patient, a girl aged 11, is a normal colour and leads a normal life. One other of the successful cases is worthy of special mention.

The patient, a married woman aged 26 (Ref. No. 0207), was deeply cyanosed and could walk only a few yards; her condition was deteriorating rapidly and she obviously had little time to live unless something could be done to help her. She was even unable to eat an adequate amount of food because of the severe dyspnoea that followed a meal. All her symptoms have been relieved; she is an excellent colour and leads a normal life; she has gained over a stone in weight since her operation in December last. Also significant is the fact that, although she had been married for several years and wanted children, she had never conceived. Although warned against an early pregnancy, she has become pregnant. In view of her good general condition the pregnancy is being allowed to continue. It will indeed be gratifying if she is safely delivered of a live child.

Infundibular Stenosis

Although valvular stenosis does occur in Fallot's tetralogy it is certain that infundibular stenosis is more common, and the more cases one sees and operates upon the clearer it becomes that if direct relief of the obstruction is to be at all widely applicable to these cases it must include direct attack upon the infundibular stenosis itself. This is, of course, a far more complicated matter than relief of a valvular stenosis by valvulotomy, since it involves resection of a portion of the actual wall of the active ventricular muscle and not simple division of a narrowed valve at the exit of the ventricle: it has been said that even if it were possible to operate upon the infundibular obstruction it would probably recur after the operation. It has also been suggested that since we have such an effective procedure as the Blalock–Taussig operation it is scarcely justifiable to embark upon a more elaborate intracardiac one.

It has already been pointed out that surgery is not static and therefore the feasibility and efficacy of direct relief of the infundibular stenosis must be considered carefully and critically. A moment's reflection shows that if it were possible to relieve this infundibular stenosis it would be far better than short-circuiting it as in Blalock's operation. The obstruction would then be relieved directly and no

new strain would be thrown upon the heart by the creation of the artificial ductus arteriosus.

Moreover, another important advantage would be conferred by the operation. In Fallot's tetralogy the cyanosis and disability are due to two things—the pulmonary stenosis which allows too little blood to go to the lungs, and the septal defect with an overriding aorta which allows a mixing of venous with arterial blood. The Blalock operation increases the blood supply to the lungs but does not relieve the right-to-left intracardiac shunt (except in so far that it pays back into the pulmonary circulation imperfectly oxygenated blood that has failed to enter the pulmonary artery and has passed into the aorta). I wish to emphasize that these two factors are to a great extent interrelated, a fact to which insufficient attention has been given.

If the degree of pulmonary stenosis is severe, the blood, in ventricular systole, cannot pass quickly enough into the pulmonary artery and must be diverted into the overriding aorta; if the degree of pulmonary stenosis is slight, a far greater portion of the blood ejected during ventricular systole can pass into the pulmonary artery and a correspondingly smaller amount passes into the aorta (Fig. 1).

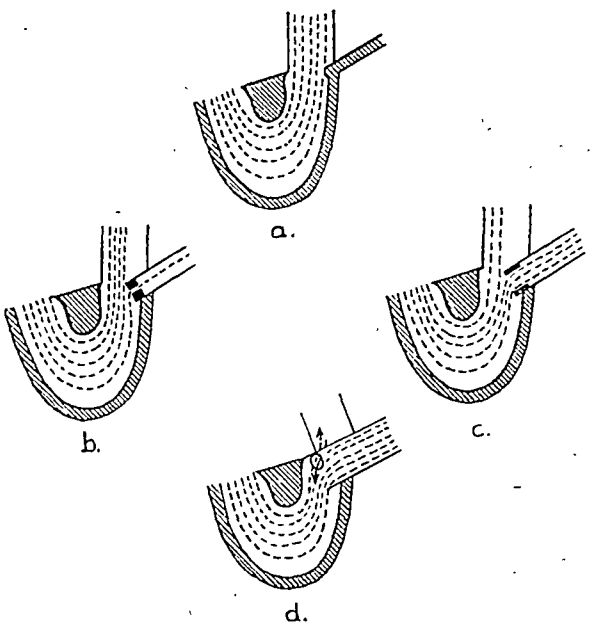

FIG. 1.—Diagrams illustrating the importance of the degree of pulmonary stenosis in determining the amount of right-to-left shunting that occurs in the presence of an overriding aorta. In *a* there is complete pulmonary atresia, and all the blood passes into the aorta. In *b* there is a high degree of pulmonary stenosis and most of the blood from the right ventricle enters the aorta. In *c*, in which the pulmonary stenosis is less or has been relieved by operation, more blood enters the pulmonary artery and correspondingly less escapes into the aorta. In *d*, in which there is no pulmonary stenosis and only a small interventricular septal defect, there is no appreciable mixing.

Nature itself provides us with instances of the two extremes: on the one hand we have the example of complete pulmonary atresia in which the exit of blood from the right ventricle into the pulmonary artery is completely prevented (Fig. 1*a*); on the other hand we have pure interventricular septal defect with no pulmonary stenosis ("maladie de Roger"), in which no apparent right-to-left mixing occurs (Fig. 1*d*). It is true there is no overriding aorta.

In the case of complete pulmonary atresia, if we imagine opening up even a small lumen to the pulmonary artery, instead of all the blood passing through the right-to-left shunt some could pass into the pulmonary arteries. Conversely, if we imagine a pulmonary stenosis supervening in the "maladie de Roger," it is clear that a proportion of the blood normally ejected by the right ventricle into the pulmonary artery would pass through the septal defect, the exact amount being directly proportional to the degree of the pulmonary stenosis; if the pulmonary artery were narrowed down to complete obliteration the only exit for the right ventricular blood would be through the septal defect and thence into the aorta.

It is not unreasonable to assume that in Fallot's tetralogy there is a similar correlation between the severity of the pulmonary stenosis and the severity of the right-to-left shunt. As the years pass by, the stenosed channel becomes more rigid, warty vegetations appear, and the lumen is further diminished. As the passage to the lungs becomes more difficult, correspondingly more blood escapes into the systemic circulation, and cyanosis and disability become worse. The pulmonary obstruction functions rather like the sluice-gates of a river, regulating the amount of flow that occurs in the main stream or is diverted to a side stream. The effect of direct operation upon the pulmonary stenosis and of relieving the obstruction to the outflow of the right ventricle will be not only to increase the amount of blood going to the lungs but to lessen the amount passing through the shunt and causing venous arterial mixing (Fig. 1*c*).

The same mechanism is seen, although it functions in a more roundabout manner, in pulmonary valvular stenosis without an interventricular septal defect but with a patent foramen ovale. There may be little or no cyanosis in early life, but as the stenosis becomes more severe the pressure behind the obstruction rises and the effect is eventually felt on the right atrium, with consequent passage of blood from right to left through the interatrial septum. By dividing the stenosed pulmonary valve one not only allows more blood to go to the lungs but the back-pressure effect is also relieved and the interatrial right-to-left shunt is corrected. The cyanosis and disability are thus relieved by a dual mechanism.

This correlation between the degree of the pulmonary stenosis and the amount of right-to-left shunt appears also to offer a very reasonable explanation for the severe attacks of cyanosis, often with loss of consciousness, that are apt to afflict these patients. They occur with slight exercise or even when the patient is at rest. Although in older patients the walls of the stenosed infundibular canal may become very fibrous and rigid, in most patients, and certainly in young children, there is much more muscle than fibrous tissue surrounding the narrowed channel. One of the functions of muscle, in addition to that of contraction, is to exhibit tonus, and this tonus can vary. It is not improbable that variation of tonus of the encircling muscle may affect the functional lumen of the already narrowed infundibular channel, diminishing further the blood flow to the lungs and also causing more blood to be diverted into the systemic circulation through the intracardiac shunt.

This concept of variations in the tonus of cardiac muscle resulting in corresponding variations in the distribution of blood through the various anomalous channels, even though largely theoretical, provides a satisfactory explanation for the dramatic variations in the patient's cyanosis and general condition. It is, in fact, difficult to picture a more satisfactory explanation. Moreover, in the heart of Fallot's tetralogy, as the cardiac output increases with exercise, the narrowed pulmonary canal is too small to take advantage of the greatly increased blood flow, most of which is

inevitably diverted into the systemic circulation, thus rapidly increasing the cyanosis and disability.

If these arguments are true it follows that by a direct operation on the stenosis, which relieves the obstruction to the blood flow to the lungs, we increase the flow of blood to the lungs and at the same time diminish the escape of venous blood into the systemic circulation through the intracardiac shunt. During exercise the pulmonary circulation is further able to avail itself of the increased cardiac output. The procedure, therefore, would appear to be superior to a simple short-circuiting operation that neither relieves the obstruction nor lessens the shunt. The only way to stop the venous-arterial shunt completely would be to close the interventricular septal defect and correct the overriding of the aorta. It would seem very difficult to achieve both these things by operation; at present we can only hope to lessen the degree of the shunting by opening up the pulmonary channel.

Observation of the types of patient presenting themselves for treatment has impressed me that it is possible to separate out two rather rough groups. Not all patients fall into these two groups; some are intermediate, but they do reveal two extremes. In one group are the very blue and disabled patients, in particular the younger children with severe heart lesions; the other group is composed of older patients, in the middle or late teens, who have less cyanosis and disability and are often bright and intelligent, have done well at school, and are held back by their cardiac condition. In the first group it is of first importance to save life. Most of the patients in it are threatened with an early death unless they are relieved in some way by operation; they are quite unable to make any use of educational facilities and are unlikely to become useful citizens. Nobody can question the justification for using the Blalock–Taussig operation to relieve these patients; the operation is life-saving and confers great benefits in the relief of severe disability.

I am always more worried about the use of the Blalock–Taussig operation in the second group—not because it will not lessen cyanosis and disability and enable the patient to make full use of his educational and mental attainments, but because of the uncertainty of the later prognosis attached to the artificial ductus arteriosus. It is for this reason that I have always felt a lurking doubt when viewing the present good result after a Blalock's operation on these patients. It would be so much more satisfactory if there was not in the background the uncertainty that in another five to ten years serious effects of the artificial ductus arteriosus will appear. It would be much better if one could feel that a bright and intelligent boy or girl of 10–18 could be spared this doubtful future.

By direct operation on and relief of the obstruction in the pulmonary channel one might be able to achieve this, and I feel that this provides another powerful argument in favour of operative relief of the infundibular stenosis; certainly so in the older and less disabled group, but by no means excluding the more severe or most severe cases.

If these arguments are correct the advantages of direct operation upon the infundibular stenosis are manifest. I am happy to be able to state that the operation is certainly possible, because I have already performed it successfully in five cases. It is as yet too early to know whether there will be a tendency for the stenosis to recur, but up to now there seems to be progressive improvement rather than regression with the passage of months. The newly made wider channel seems to be progressively increased by the improved circulation; it is of course possible that the passage of years may tell a different story, but so far the results have been extremely encouraging.

The development of an operation of this sort must be based, among other things, on a clear conception of the surgical and pathological anatomy of the condition. A complete description of this is impossible here and must be dealt with in a separate report. It must suffice to say that there are considerable variations in the position and character of the stenosis, which may be placed a short distance below the pulmonary valves or as much as several centimetres lower down in the ventricle. Fig. 2 shows diagrammatically the position and form of most of the usual types; and Fig. 3 shows two types similar to those in Figs. 2*c* and 2*d* but with a muscular outer wall to the infundibular chamber. Especially important is the variety seen in Fig. 2*d*, in which the stenosis is situated low in the ventricle and there is a large infundibular chamber separated from the main ventricular chamber by a small ostium.

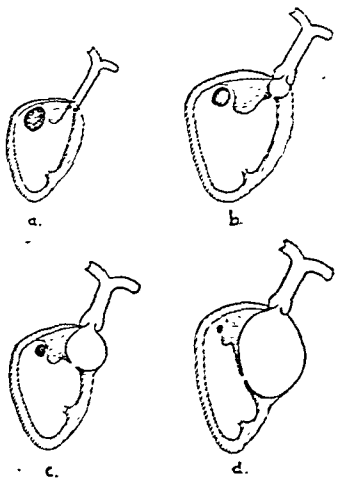

FIG. 2.—Diagrams illustrating certain forms of the commoner types of infundibular stenosis. In *a* there is a high degree of pulmonary hypoplasia with a bicuspid valve and stenosis lying just below the valve in a narrow muscular channel. In *b*, the commonest type, there is a high infundibular stenosis. In *c* there is a small infundibular chamber with a very thin fibrous wall. In *d* the thin-walled infundibular chamber is large.

This type is usually easily recognized radiologically before operation by a well-marked convex projection on the left border of the heart shadow just below the pulmonary artery; it is thrown into greater prominence in the right anterior oblique view, and the chamber itself is clearly demonstrated by angiocardiography. In view of the ease of recognition, and the considerable clearance below the pulmonary valves afforded for operative manipulations, this was the type chosen for the first resections. This resection was done by inserting a special punch through an incision in the wall of the right ventricle below the stricture. In some cases a finger has been passed into the heart, both to examine the local state of affairs more exactly and to dilate further the pulmonary canal. In one case finger dilatation was all that was done, and a good result followed.

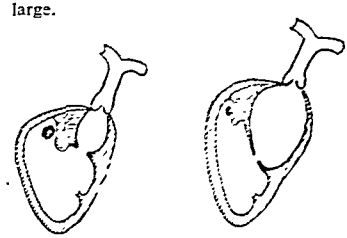

FIG. 3.—These two types are similar to those shown in Figs. 2*c* and 2*d*, except that the outer wall of the infundibular chamber is muscular.

A complete clinical account of the five successful cases will be given elsewhere in conjunction with Dr. Maurice Campbell.

In addition to these five successful cases there was one patient who died. This was a very blue woman aged 35 who, like all these patients over the age of 20, was an

extremely bad risk; an operative diagnosis of a valvular stenosis was made and a valvulotome was passed, although as soon as it was introduced it became clear that a more complicated condition existed. She died, and post-mortem examination revealed an infundibular stenosis situated just below the valves. Although not strictly an example of infundibular resection, it was felt that this fatal case should be included in the series.

Comment upon Direct Cardiac Operation

These direct operations upon the heart involve considerable anxiety, and many difficult and complex problems arise. This is not surprising, as they constitute virtually an entirely new field of surgical endeavour. Even more than in the case of the Blalock–Taussig operation they are definitely not for the lone operator, but demand the work and attention of an enthusiastic, loyal, and courageous team. Quite apart from the technical details of the actual operation upon the heart itself, there are the abstruse problems that arise in connexion with the avoidance or treatment of cardiac arrest or of the various severe arrhythmias that may occur during the operation; in addition there is the ever-present danger of temporary or permanent damage to the brain occurring as a result of arrest of, or interference with, the cerebral circulation. The various problems are being elucidated, and answers to them are being sought and found; progress is being made all the time, and we hope that the final results will justify the efforts. It is certain that by this means alone can we settle the question of the feasibility or otherwise of direct operations upon the heart for the relief of pulmonary stenosis.

It has been suggested that all this hard, anxious, and difficult work is scarcely justified for patients with congenital cyanotic heart disease, since so many of them are poor lives in any case and do not merit the effort. Morally, of course, this attitude is quite indefensible, but apart from this it must be emphasized that the issue is a far larger one and should be recognized as such. Although at present most of our efforts are being directed towards the surgical relief of congenital heart abnormalities, there is also the much vaster and more important field of the acquired heart lesions. Up to now very little has been achieved in their surgical relief, but the knowledge and experience gained by direct cardiac surgery for the congenital cases must help the development of successful operations for acquired heart lesions. We have, in fact, already at Guy's one successful case of the operative relief of post-rheumatic mitral stenosis.

Both these operations upon the heart itself and the indirect operations of the Blalock–Taussig type are tiring and anxious procedures, involving much care, responsibility, and hard work. Fortunately they have their happier side, and we are in large part recompensed for the long and difficult hours by seeing the almost miraculous change in the children themselves and in witnessing the joy and relief of the parents when they see their children running about happily and without effort like other children.

SOME ASPECTS OF POLIOMYELITIS IN NEW ZEALAND

BY

J. E. CAUGHEY, M.D.N.Z., F.R.C.P., F.R.A.C.P.

(From the Auckland Hospital)

From the study of poliomyelitis in different parts of the world it seems apparent that the clinical picture of the disease varies from country to country and from time to time in a given locality. The occasional case of endemic poliomyelitis with a minimal prodromal illness and sudden onset of paralysis, as is common in the United Kingdom, is poles apart from the type of case which occurs in epidemic form in New Zealand, where there is a high mortality and the prodromal illness is often an acute influenza-like affair with marked muscle spasm. As a result, concepts of the disease and methods of treatment in the U.K. and those of New Zealand and the North American continent are widely divergent, and we have the paradox of skilled observers in the U.K. stating that they have never seen muscle tightness in poliomyelitis, whereas competent observers in other countries aver that muscle tightness occurs in every patient with poliomyelitis. Treatment has varied accordingly.

In the United Kingdom in the past, apart from occasional minor epidemics, the disease has been endemic, but there has been a rising incidence in the last two years, and it seems probable that poliomyelitis may be about to shed its cloak of endemicity and appear in full-dress epidemic form. Whether such a change is a result of a rising virulence or is due to the advent of a new strain of poliomyelitis is not yet apparent, but if severe epidemic poliomyelitis does occur in the U.K. it seems probable that the clinical picture will be different from what it has been in the past. In view of this it might be of value to place on record some aspects of an epidemic of poliomyelitis which occurred recently in New Zealand, where poliomyelitis has been endemic since 1887 but where in addition there have been major epidemics at regular intervals, as in 1916, 1925, 1937, and 1948 (Department of Health, New Zealand, 1938).

The New Zealand Epidemics

Seasonal Incidence.—In the recent epidemic in Auckland (population 354,000), 250 patients were admitted between November, 1947, and September, 1948 (Hughes, 1949), and thereafter occasional cases occurred up till April, 1949. The onset and main intensity of the epidemic occurred in the summer, in the first three months of the outbreak. Thereafter the epidemic smouldered for 14 months. Previous epidemics in New Zealand have occurred in the summer months, whereas in an epidemic among New Zealand troops in Egypt (Caughey and Porteous, 1946) the incidence was highest in the months of January and April, unlike that of other epidemics in the Northern Hemisphere, which tend to fall in the summer months, between July and October.

Age Incidence.—The 250 patients admitted comprised 188 children and 62 adults. A study of the age incidence of notified cases in this and previous epidemics (Table I) shows a steady increase in the incidence of patients over 16 years and a fall in the 0–5 age group, in keeping with the definite shift to the higher age groups noted in the poliomyelitis statistics of New York City and elsewhere.

TABLE I.—*Age Incidence in New Zealand Epidemics*

Age (Years)	1916		1924–5		1936–7		1947–8	
	Cases	%	Cases	%	Cases	%	Cases	%
0–5 ..	200	59·3	641	55·3	245	27·3	86	34·4
6–10 ..	65	19·3	273	23·6	291	32·5	70	28·0
11–15 ..	27	8·0	115	9·9	177	19·8	32	12·8
16 + (adult)	45	13·3	130	11·3	209	20·4	62	24·8

Age and Severity of the Disease.—Study of Table II shows that the severity of the disease was greater and the mortality rate higher in the older age groups, while the morbidity rate was higher among the younger age groups.

TABLE II.—*Age Groups*

Years:	Under 1	1–5	6–10	11–15	16–
No. of patients ..	6	80	70	32	62
Deaths	0	0	1	2	9
% mortality ..	0	0	1·4	6·3	14·5

Contact Cases and Multiple Cases.—For the correct assessment of "multiple" cases consideration must be taken of mild poliomyelitis (stage 1), but it is of interest to note that of those cases regarded as severe enough for admission to hospital 16 came from seven families. A nurse and a medical officer who were working in direct contact with patients developed the disease, and 17% of the patients admitted were known to have had contact with positive cases.

Severity of Disease in Relation to Onset of the Epidemic.—During the first three months of the epidemic the cases were more severe, with a more acute onset, greater febrile disturbance, marked muscle spasm, and more paresis. The incidence of respiratory paralysis and bulbar palsy was higher, as was the mortality rate, 10 out of the 12 deaths occurring in the first two and a half months of the epidemic. Thereafter the severity of the cases steadily declined, many presenting with a mild upset with muscle stiffness, and often with a normal spinal fluid.

Portal of Entry.—Interest in tonsillectomy as a possible portal of entry for poliomyelitis was stimulated by the report by Francis *et al.* (1932) of a family of five children in Ohio who all had tonsillectomy performed on the same day. All developed poliomyelitis a few days later and three died. From the outset of the epidemic in Auckland the local health authorities and doctors advised against tonsillectomy and nasal operations while the epidemic was raging. The first 125 patients admitted were studied with this matter in mind, and in no case could recent tonsillectomy be held to be a factor in the development of the disease. One patient had undergone a nasal operation several days before the onset of the disease, and one patient had had a tooth extracted two weeks before admission.

Clinical Manifestations

The clinical picture of acute poliomyelitis in the past has been divided into a pre-paralytic and a paralytic stage or into "abortive" and paralytic poliomyelitis. In this study we have found it convenient to regard the disease as developing in three stages: stage 1, a stage of "minor illness"; stage 2, a stage with evidence of muscle spasm, with or without changes in the spinal fluid; and stage 3, in which the disease has progressed to definite paresis.

Stage 1: "Stage of Invasion"; "Minor Illness" of Poliomyelitis; "Abortive" Poliomyelitis.—During the epidemic a large number of adults and children presented with evidence of a minor febrile upset lasting two or three days and then settling without residual upset. Paul, Salinger, and Trask (1932) investigated a group of these patients among household contacts of cases of undoubted poliomyelitis and studied comparable control homes. They found a high incidence of so-called "minor illness" in the positives as compared with the contacts, and in comparable communities the incidence of "minor illness" was six times more common where poliomyelitis cases were occurring. The "minor illness" took one of two forms—acute febrile illness with sore throat, headache, and vomiting, settling after 24 to 36 hours, or mild upsets referable to the upper respiratory or the gastro-intestinal tract, with "cold" or diarrhoea. An investigation was carried out on 12 of these patients, and in two the diagnosis of poliomyelitis was established by monkey inoculation of nasopharyngeal material.

In the New Zealand epidemic Thompson (1948) carried out a careful investigation to discover how the epidemic started and how much minor illness related to the poliomyelitis had occurred (*a*) among household contacts, (*b*) in other persons residing in the same neighbourhood, and (*c*) in those parts of the urban area least affected by the epidemic. The investigation showed that the epidemic was preceded and accompanied by a large number of cases of "minor illness" of varying severity characterized by fever, headache, sore throat, vomiting, and diarrhoea. The ratio of this suspect minor illness to positive cases was very high—300 to 1. These patients were seldom admitted to hospital. They presented with an illness more or less characteristic but not specific. Most of them were probably suffering from stage 1 poliomyelitis.

Stage 2: "Pre-paralytic Poliomyelitis"; "Abortive Poliomyelitis."—Of the first 224 patients admitted to hospital 114 were in stage 2 and had had the "minor illness" of stage 1, but in addition they had developed pain and stiffness of muscles of the limbs and back and showed evidence of muscle spasm but no paresis. In the earlier days of the epidemic this type of patient usually had changes in the spinal fluid, but in the later months many stage 2 patients had a normal spinal fluid.

Stage 3: Paralytic Poliomyelitis.—Of the first 224 patients admitted 110 had evidence of paresis—76 moderately severe and 34 severe, 12 of whom died.

Signs and Symptoms

Headache.—Headache was a common presenting symptom. In a previous epidemic among New Zealand troops in Egypt (Caughey and Porteous, 1946) headache occurred in 39 out of 40 patients. In the present epidemic 45.4% of the patients complained of headache, which was usually throbbing in character and generalized or frontal in situation; but the series contained a large number of children below 5 years old, which made accurate record-taking on this point difficult. In some, headache first appeared three days after the onset, and might have been connected with the invasion of the central nervous system. Vomiting accompanied the headache in 17.4%.

Fever.—A study of the temperature charts of 115 patients (31 adults and 84 children) shows that, in general, the temperature range was highest in cases in which death or severe paralysis occurred (Table III).

Most of the patients had been ill for a number of days before admission, making estimation of the duration of fever difficult. The duration of fever after admission tended to be longer in those with severe paralysis than in those with slight or no paresis.

Table III.—*Height of Fever and Relation to Mortality and Severity of Paralysis (115 Patients)*

	Cases	Range Max. T.	Av. Max.	In Hosp.	Total
Adults (31):					
Fatal cases ..	5	101·4–104·6° F. (38·55–40·3° C.)	103·1° F. (39·5° C.)	2	4
Severe „ ..	13	99–103·4° F. (37·2–39·7° C.)	101·8° F. (38·8° C.)	5·5	8·5
Mild „ ..	7	98·4–103° F. (36·9–39·4° C.)	100·1° F. (37·85° C.)	4·5	7
Non-paralytic	6	98·6–105° F. (37–40·6° C.)	102·6° F. (39·2° C.)	3	5·5
Children (84):					
Fatal cases ..	3	102–104·2° F. (38·9–40·1° C.)	103·1° F. (39·5° C.)	3	4
Severe „ ..	24	100–104·4° F. (37·8–40·2° C.)	102·2° F. (39° C.)	4·5	7
Mild „ ..	24	99·4–104·8° F. (37·4–40·45° C.)	101·7° F. (38·75° C.)	3·7	6
Non-paralytic	33	99·6–103·8° F. (37·55–39·9° C.)	101·5° F. (38·6° C.)	4·7	6·7

Evidence pointing to a gastro-intestinal invasion was scanty. Diarrhoea developed in 6.4% at the onset and vomiting occurred in 32%. In 20% there was complaint of sore throat and evidence of nasopharyngeal congestion, which might point to a respiratory-tract invasion.

Pain.—Discomfort in the form of aching muscles, sometimes amounting to pain, was often a feature in the acute stage of the illness; and pain on movement, palpation, or muscle-stretching was frequently severe. This discomfort caused irritability and exhaustion, and prevented sleep. It was relieved by hot packs in practically all cases.

Hyperaesthesia of Skin.—This was sometimes a feature in the early phase of the illness. One adult complained of tenderness of the calf, and on light massage the skin was found to be extremely tender. The latter persisted for two days, but tenderness of the muscle persisted for five days. No weakness developed, but the ankle-jerk was lost. A nurse on the fourth day of her illness was hyperaesthetic over the abdominal wall and lumbar region, and when admitted to the sick bay was found to have tenderness of the right deltoid and in the abdominal and lumbar muscles. An adult male noticed that when he rubbed the extensor surface of his left forearm "the skin tingled and felt as though it had been slightly burned." This hyperaesthesia persisted. In four days he developed weakness of the left arm, more pronounced in the flexor muscles of the forearm.

Muscle Spasm

When our means of examination for this sign was adequate we detected muscle spasm in 100% of patients. A careful search was made for muscle spasm by inspection and palpation and by taking muscle groups through their full range of movement in order to observe the effect of stretch. This examination was more easily carried out with the patient in shorts, lying on a plinth.

Muscles in a state of spasm were often very tender, and were firmly contracted, bringing about deformity such as head retraction, deviation or rotation of the head, elevation of the shoulder, lordosis or scoliosis, flexion at the knees, or plantar flexion of the foot.

Muscle spasm was induced by stretching the muscles. The spasm developed at the onset of a phase of painful stretch as though pain had set up an abnormally active stretch reflex. Electromyographic studies tended to confirm this (Caughey, in the press). Once spasm had developed, further stretch was prevented by pain and the degree of spasm. The common sites of muscle spasm were the extensors of the neck and back and the hamstring muscles, the trapezius muscle, the muscles round the shoulder girdle, the quadriceps, and the gastrocnemius.

Muscle spasm was aggravated by massage, premature weight-bearing or other unsuitable motor activity, exposure to cold, and infection such as virus influenza. It was relieved by heat: this will be discussed later.

Duration of the Pre-paralytic Period

The duration of this period is important from the point of view of prognosis regarding the onset of paralysis. In this epidemic it was estimated from the first sign of the disease, and the average was 4.7 days, with a range of 1–18 days. In a previous epidemic among adults in the Middle East the average was 4.6 days. Another useful guide to prognosis of paralysis was fever; it was found that while fever persisted prognosis in respect of paresis had to be guarded.

Stage 3: "Paralytic Poliomyelitis"

Apparent paresis in poliomyelitis may be due to muscle spasm, to reflex inhibition or involvement of the anterior horn cells, or to a combination of these. Much of the recovery from paresis which occurs after it has developed is due to removal of reflex inhibition and abolition of spasm.

The onset of paralysis at the height of the epidemic was usually heralded by muscle-tightness and pain, muscle fasciculation, and occasionally hyperaesthesia of the skin. The incidence of paresis was much higher in the early months of the epidemic. Reflexes were variable; in some patients they were exaggerated in the early stages of the disease, and at times were absent or reduced without paresis. Where deep reflexes were preserved in the presence of paresis, the weakness was usually due to reflex inhibition or muscle spasm.

As a rule paralysis was maximal within 48 hours of its onset—the weakness being localized to one muscle group of one limb—and at times there was generalized weakness, with or without a more local weakness. The paralytic cases could be divided into spinal, bulbar, and encephalitic groups, with considerable overlapping. In the spinal type the weakness more often involved the lower limbs and was usually asymmetrical. Transitory retention of urine occurred in some, but this invariably cleared up after a few days. In the bulbar cases the reticulum wherein lie the 9th, 10th, 11th, and 12th nuclei was at times picked out in pinpoint fashion so that cardiac and respiratory centres were partially spared while the 9–10 complex was affected, causing difficulty in deglutition, choking, and nasal regurgitation. In other bulbar patients there was early nasal regurgitation and a nasal voice; mucus accumulated in the throat, the nasopharynx and the palate became intensely hyperaemic, the pulse was rapid and temperature high, the blood pressure was low, the respirations were jerky and irregular, fasciculations developed about the face, there was cyanosis, and finally coma ensued, with death.

Five patients who were diagnosed as cases of polioencephalitis were seen among the children; they passed from the pre-paralytic stage into a comatose state. Recovery from the comatose state occurred in two to seven days, the patient being left with a residual paralysis of a limb or involvement of the cranial nerves, and twice there was no residual paresis, making the diagnosis uncertain.

Clinical Pathology

A study of the blood picture yielded little useful information. The total white blood cells ranged from 2,000 up to 20,000. In general it could be said that the cases with a high leucocyte count had a high polymorphonuclear count in the cerebrospinal fluid.

The cerebrospinal-fluid pressure was usually moderately high. The fluid at times was crystal-clear, but in cases in which the count was high it was slightly hazy or even turbid, and occasionally developed a fine fibrous clot on standing. The C.S.F. cell count was found to vary enormously, and ranged from 5 to 2,000 or more. In the first day or two there was usually a preponderance of polymorphs or, rarely, the cells were all lymphocytes. This was probably determined by the stage of the disease at which lumbar puncture was done. After seven or eight days the count usually fell and became entirely lymphocytic in type, and after two to three weeks it returned to normal. The height of the cell count was no guide to whether paralysis was likely to develop. The protein content at the outset was normal or slightly raised. In what has been described as the classical picture, the protein content rises as the cell count falls. This was not borne out in our experience. the average protein in 41 cases was 56 mg. per 100 ml., with a range of 12–174 mg. The glucose level was undisturbed and chlorides were unchanged. However, as with other aspects of poliomyelitis, the cerebrospinal fluid changes were variable, and paralysis occurred with a normal fluid, or, on the other hand, marked changes occurred in the fluid without paralysis.

Management of the Outbreak

When it seemed likely that the outbreak in Auckland would assume epidemic proportions the local health authority and the hospital made plans to handle the situation.

Health Department.—All practitioners were circularized and instructed in preventive measures, such as the avoidance of tonsillectomy, nasal operations, and teeth extraction. To this, in future, should be added detailed information concerning the diagnosis of the suspect minor illness (stage 1) and the importance of treating any such suspect "minor illness" by complete rest to avoid unnecessary aggravation of muscle spasm and paresis by activity during the pre-paralytic period.

In addition, a panel of doctors with experience of poliomyelitis was set up to screen all suspect cases before admission to hospital. Only in exceptional circumstances were patients admitted to hospital without first being examined by one of this panel. This kept the admission rate to hospital down to reasonable proportions and ensured that suspect illnesses were carefully handled.

Hospital Preparations.—Beds were set aside in the infectious-disease block; the number of these could be readily expanded. Convalescent wards were also set aside to which patients could be transferred after three to four weeks. The medical care of all patients was in the hands of a paediatrician and a neurologist, the orthopaedic surgeons and otolaryngologists being called in consultation if necessary. Ultimately patients passed to the care of the physician in charge of the physiotherapy department. Three Kenny-trained technicians were brought to the country to assist other physiotherapists in the management and treatment of patients. A number of lay women were engaged as "packers"; with instruction they quickly became efficient and rendered invaluable service.

Treatment

In the acute stage of the illness all patients were nursed on a firm flat mattress with a low pillow, and a small one under the knees, in a position of comfort, the feet up against a foot-board at the bottom of the bed. If necessary sandbags were used to control rotation of the legs, and the pressure of bedclothes was taken by a cradle. Apart from these measures no splinting was employed.

Hot Packing.—From the outset treatment was directed to the relief of muscle spasm. In severe cases full packs to the trunk and all four limbs were used. In less severe cases packs were sometimes applied to the part affected. Packs were made of fine woollen material cut suitably for each part. They were immersed in boiling water, were wrung dry in an extractor, were applied at high temperature, and were then covered with blanket material and pinned in position. An efficient extractor was an important adjunct to treatment, as packs could then be applied at high temperature without burning the patient. Packs were applied at hourly to four-hourly intervals, dependent upon the severity of the case. At night packing was stopped, although occasionally packs were then used for the relief of pain. In the event of excessive sweating in the packs, saline was given to avoid salt depletion. The results of this treatment have to be interpreted with caution, but certain benefits undoubtedly accrued. Patients who were unable to sleep on account of pain and restlessness were relieved of their discomfort and usually slept soundly after a day of hot packing. Muscles in a state of tightness were relieved of their spasm, and re-education and passive joint movement could be carried out almost from the outset. The skin remained in a healthy state and was soft and pliable; this was especially apparent in the skin of the chest wall in patients with severe intercostal and respiratory involvement.

Passive Movement.—This was usually begun one or two days after the onset of treatment. Joints were gently taken through their range of movement once or twice a day after muscle relaxation had been attained by hot packs. Where relaxation of a muscle group was incomplete after hot packing for several weeks more forcible stretching of the tight muscle group was carried out daily.

Re-education.—This was usually started after three or four days, dependent upon the severity of the illness. Any unaffected muscles were gently exercised, and affected muscles were trained in order to correct any reflex inhibition and disturbance of reciprocal innervation which may have arisen. Ambulation in general was begun as soon as possible, making free use of elbow crutches and giving careful instruction in walking.

Treatment of Patients with Respiratory Paralysis.—Having decided that a patient was likely to require treatment in a respirator, the sooner the step was taken the better. Such cases invariably were endangered by aspiration of fluid, food, vomitus, or mucus. If it was not possible to keep the throat clear by suction, tracheotomy was carried out, all fluids were stopped by mouth, and the patient was fed by the intravenous route, using glucose and saline and daily a bottle of protein hydrolysate or plasma. Prophylactic penicillin was given. By this means patients could tide over a week or two, by which time the general condition had often improved. We feel that these measures were life-saving on three or four occasions.

Results of Treatment

A review of the first 224 patients treated in this manner shows that the mortality rate was 5.4% (12 patients); 22 were severely paralysed, 76 moderately paralysed, and 114 had no paresis. Of the 76 moderately paralysed 64 had completely recovered and 5 were still moderately paralysed at the end of one year. At the end of nine months 5 were still moderately paralysed, and at the end of three months 2 were moderately paralysed. Of the 22 severely paralysed

8 were completely recovered, 7 still moderately paralysed, and 5 severely paralysed.

Hence out of 224 patients 12 died and after 12 months 32 (14.2%) still had residual weakness. The remainder had made a complete recovery.

It is a pleasure to express one's appreciation of Dr. Elizabeth Hughes, with whom I worked in this epidemic; Dr. Rowatt Brown, the Director of Physiotherapy; Dr. Hunt and Dr. Barker, and the house-physicians, physiotherapists, and nursing staff, whose skill and devotion made this work a pleasure.

FAILURE OF AUREOMYCIN IN EXPERIMENTAL MELIOIDOSIS*

BY

J. C. CRUICKSHANK, M.B., Ch.B., D.T.M., Dip. Bact.
(From the London School of Hygiene and Tropical Medicine)

No satisfactory agent for the treatment of melioidosis has yet been described. The disease in its generalized form is almost invariably fatal, but recovery in cases with localized superficial abscesses in which serious constitutional symptoms were absent have been reported. These reports have recently been reviewed by Green and Mankikar (1949), who also summarize the literature relating to the treatment of melioidosis with sulphonamides and antibiotics, and describe experiments made with certain of the newer drugs.

The evidence suggests that sulphadiazine is the most promising of the sulphonamides, and that a full course of this drug should be given. Penicillin, in concentrations attainable in the blood, is ineffective, but may be of value for injection locally. Streptomycin and "polymyxin" have no inhibitory effect on *Pfeifferella whitmori*, but chloramphenicol in concentrations obtainable in the blood (60 μg. per ml.) is highly inhibitory *in vitro* and is suggested for clinical trial. No report of the effect of chloramphenicol *in vivo* is yet available.

Through the courtesy of Messrs. Lederle a quantity of "aureomycin" was made available to the Medical Research Council, and since there seemed to be no data relating to the use of this antibiotic in infections with *Pf. whitmori* it was considered worth while to carry out a small laboratory trial. The strain used had been isolated from an abscess of a severe human case of melioidosis.

*A report to the Medical Research Council.

In-vitro Tests

Tests of the inhibitory action of aureomycin *in vitro* were made by the method recommended by Paine, Collins, and Finland (1948). A series of tubes was set up, each containing 0.5 ml. of heart broth and a concentration of aureomycin falling from 200 μg. per ml. by twofold dilutions to 0.8 μg. per ml. To each tube was added 0.5 ml. of a broth culture of *Pf. whitmori* standardized by opacity to 10 million organisms per ml. The concentration of aureomycin now ranged from 100 μg. per ml. to 0.4 μg. per ml. A standard loopful from each tube was inoculated on the surface of an agar plate containing the same concentration of aureomycin.

Strains of *Str. pyogenes* and of *Bact. coli* (faecal type), regarded respectively as typical sensitive and resistant bacteria, were simultaneously tested in broth-tubes and on parts of the same plates. The tubes and the plates were incubated for three days at 37° C. The results are shown in Table I. It will be noted that *Pf. whitmori*, which was inhibited by 12.5 μg. per ml. of aureomycin in broth and by 6.3 μg. per ml. on the plate, lies more closely to *Bact. coli* in its sensitivity than to the haemolytic streptococcus. According to Schneierson and Toharsky (1949) levels of up to 2 μg. per ml. are attained in the blood four hours after a single oral dose of 500 mg. in healthy subjects, falling after 12 hours to levels of the order of 0.49 μg. per ml.

In-vivo Tests

Although the tests made *in vitro* did not show great promise, it was decided to make a trial of the antibiotic in experimental infection in guinea-pigs. The orthodox procedure in a trial of this kind would be to estimate the average lethal dose of the infecting strain with adequate numbers of animals, and to proceed to a trial of the therapeutic agent, observing treated and untreated animals inoculated with a suitable infecting dose. It was considered wise, however, to arrange in the first instance a small-scale trial which could be completed quickly. If aureomycin showed any promise a fuller trial would then be made. One advantage of this arrangement was that it reduced the number of persons required to handle the animals infected with *Pf. whitmori*, which is reputed to be a highly dangerous organism in the laboratory. A special animal-room was set aside and a technique devised to minimize the hazards associated with the possible development of ulcerative lesions and the scattering of infected litter.

As the virulence of the strain was unknown, nine different infecting doses, falling in decimal series from 500 million to 5 organisms, were injected in suspension in quarter-strength Ringer solution intramuscularly into the leg of groups of either four or two guinea-pigs (average weight, 400 g.). Half the animals in each group were treated by the intraperitoneal injection of aureomycin morning and evening. Treatment was started at the same time as infection and continued throughout the period

TABLE I.—*Sensitivity of Pf. whitmori, Str. pyogenes, and Bact. coli to Aureomycin*

Organism		Concentration of Aureomycin in μg. per ml.									
		100	50	25	12·5	6·3	3·1	1·6	0·8	0·4	0·0 (control)
Pf. whitmori	Broth	−	−	−	−	+	+++	+++	+++	+++	+++
	Agar plate	−	−	−	−	−	+	++	++	+++	+++
Str. pyogenes	Broth	−	−	−	−	−	−	−	−	−	+++
	Agar plate	−	−	−	−	−	−	−	−	+	+++
Bact. coli	Broth	−	−	−	+	++	++	++	++	+++	+++
	Agar plate	−	−	−	−	−	+++	+++	+++	+++	+++

Degrees of growth: +++, ++, +. No growth: −

of observation. The dosages, which varied from 1 to 4 mg., are shown in Table II. The time to death was recorded, and each animal was submitted to post-mortem examination.

TABLE II.—*Treatment with Aureomycin of Experimental Melioidosis in Guinea-pigs*

Infecting Dose of *Pf. whitmori*	Days to Death					
	Untreated		Treated			
			Daily Dosage of Aureomycin			
			1 mg.	2 mg.	4 mg.	
500,000,000	4	4	4	5	–	–
50,000,000	4	4	4	6	–	–
5,000,000	4	5	4	4	–	–
500,000	5	–	–	–	8	–
50,000	4	–	–	–	5	–
5,000	5	–	–	–	9	–
500	7	7	–	–	5	10
50	4	7	–	–	4	7
5	8	11	–	–	8	10

Aureomycin was given intraperitoneally in divided doses morning and evening beginning on the day of infection and continuing until all the animals were dead

It will be observed that the strain proved to be of very high virulence. With the larger infecting doses death usually occurred on the fourth day, but with the smaller doses it might be delayed as long as the 11th day. The lesions observed were typical of experimental melioidosis, and consisted of a large abscess at the site of inoculation, suppuration of the regional lymph glands, general subcutaneous congestion, peppering of the liver and spleen with yellow necrotic areas, and multiple abscesses in the lungs. It is clear that there is little difference between the treated and the control group. There were no survivors in either group, and the slightly longer survival-time of some of the treated animals may well have been due to chance. The lesions in the treated animals did not differ from those in the controls, and the infecting organism was readily isolated from the spleen and glands.

Although it is possible that larger doses of aureomycin might have had some beneficial effect, the results of *in-vitro* tests do not suggest that this is probable, and the dosage and spacing were in fact the same as those found effective by other workers in the treatment of such infections as Weil's disease.

Summary

Pfeifferella whitmori was found not to be inhibited *in vitro* by concentrations of aureomycin lower than 6.3–12.5 μg. per ml. The course of experimental melioidosis in guinea-pigs was not materially influenced by treatment with aureomycin started at the same time as infection.

I have to thank Mr. B. Madge for efficient technical assistance.

The biennial conference of the Transport and General Workers' Union recently carried a resolution (*Scotsman*, July 14) requesting the Government to keep all aspects of their administration under constant review, with particular reference to pensions and the National Health Service, with the object of introducing improvements on a progressive basis as and when opportunity offered. The national secretary of the union's Government and municipal group said they had informed the Minister of Health of instances where they knew that certain people had been taking advantage of the National Health Service to benefit themselves, their friends, and their poor relations.

INTRACTABLE PAIN*

BY

E. B. STRAUSS, M.A., D.M., F.R.C.P.

Physician for Psychological Medicine, St. Bartholomew's Hospital

It is impossible to embark on a discussion on pain without being brought up with a bump against the insoluble body–mind problem. All experience, of course, has its origin in sensory data. Sensation becomes perception; percepts are further elaborated into concepts; concepts cluster together to form ideas and ideational constellations; and all these events undergo mnemic engramatization—i.e., the formation of memory traces. So far, it will be noted, I have been able to summarize experience in psychological terms only, without any reference to the material apparatus involved in the process. Nevertheless it is a common habit of mind to think of pain in physical terms and to draw an artificial distinction between what one is pleased to call "real" and imaginary pain, oblivious of the fact that all pain, whatever its most peripheral source of origin, is in the final analysis a psychic event.

If the words "pain" and "suffering" are mentioned outside any given context it is impossible to decide whether mental anguish is meant or pain arising direct from the body; and this is not a case of one *noumen* or descriptive category being correct in one context and in another being used as an analogue. The term "pain" covers both kinds of experience with equal justification, indicating, I would maintain, that, phenomenologically and semantically, mental and physical pain are so closely allied as to be almost identifiable one with another.

If one is compelled to think monistically it is wiser to regard pain from the psychic aspect and to disregard its material substratum, and to reserve for consideration in neuro-physiological terms the *type* of pain experienced. One can talk of a burning sensation, a boring sensation, a sensation of weight or pressure, a shooting or radiating sensation, a vibrating sensation, and a host of other sensations, all of which can be registered as painful, but not necessarily so. What converts such a sensation into a pain is, in a specially narrow sense, psychic rather than somatic, whatever fibres conduct the original stimulus. In other words, pain is an emotional as well as a sensory experience. Pain divorced from its emotional component is very different from the total experience, as is well shown after leucotomy. The emotional appreciation of pain probably depends on intact memory and unimpaired foresight; therefore leucotomized persons may be said to feel pain in the same way as an undomesticated animal does. When we empathetically suppose that the experience of pain in humans and animals is identical, we are likely to be guilty of the pathetic fallacy.

I believe that there is another important difference between pain as a sensory experience and pain as an emotional one. Pain as sensation is correctly located in the somatic segment in which it is generated in accordance with intact neural pathways. Pain as an emotional experience depends for its localization on the nature and integration of the body-image, in Schilder's sense. When the body-image is fragmented, the strangest things may happen: for example, one paraphrenic patient of mine complained that he heard voices in his stream of urine, and that the experience was extremely painful.

*A paper read in the Section of Neurology and Psychiatry at the Annual Meeting of the British Medical Association, Harrogate, 1949.

Message of Psychogenic Pain

There is no need for me to say anything here of the biological purpose of pain, except to remind you that, regarded teleologically, pain is a message to the total organism that all is not well and that a new adjustment is demanded. When the message has been delivered and adequately interpreted, pain has served its purpose and should be eliminated by all the means in our power. Psychogenic pain, using the word "psychogenic" in its narrowest sense, has a similar message to deliver—namely, that all is not well with the psyche—but the correct interpretation of the message, once it has been projected on to the body-image, is more often than not a matter of some difficulty.

Psychogenic pain, therefore, is likely to go on and on like a telephone bell that nobody answers because no one knows how to answer the telephone except a few trained psychotherapists, many of whom unfortunately, instead of answering the 'phone intelligently, go on repeating, parrot-like, a few stock phrases such as: "I am sorry you have been troubled . . . by the Oedipus complex." It is for that reason that a severe pain which does not respond to analgesic drugs is likely to be psychogenic or emotionally over-determined. On the other hand, a pain which is abolished by the subcutaneous injection of sterile saline is much more likely to be somatogenic, since physical pain, like any other sensation, is easily influenced by suggestion.

The terms "pains" and "penalties" go naturally together; in other words, there is a powerful emotional link between the ideas of suffering and of punishment. From this we can correctly adduce that the idea of pain is bound up with man's most primitive organization as a moral being. It is not only from sadistic motivations that people still cling so obstinately to the notion that corporal punishment possesses a value all its own.

The adult type of conscience is nothing more than the faculty of reason judging applications of moral values. However, there is another form of conscience which acts directly on the psyche—the unconscious conscience (i.e., the conscience with its roots in the unconscious, the *super-ego* of the Freudian schema). The super-ego, however speciously it may disguise itself, is archaic, ruthless, superstitious, pleasure-pain-governed, and swayed by Talion law. We are all influenced by our super-egos as well as by our conscience, but in mental health there is a reasonable degree of correspondence between these two regulators of conduct.

Problem of Guilt

All psychopathologists stumbled across the problem of guilt very early in their investigations. The very helpful concept of the super-ego was formulated by Freud with the idea of providing some kind of account of the "mechanics" of guilt and its resolution. Since few of us are saints—and, incidentally, the greatest saints have always been endowed with what the theologians call a "sense of sin"—the super-ego is constantly engaged in the task of restoring endopsychic harmony by means of "guilt-cancelling" devices. That is the reason, I think, why nearly all psychoneurotic symptoms are unpleasant (i.e., "painful" in the widest sense). I can think of no agreeable hysterical syndrome, with the possible exception of hysterical trance-states, and hysterical trance is amongst the rarest of psychic disorders. Even the habit of alcoholism, which is subjectively pleasant for the time being, is punished by agonies of alcoholic remorse and finally by painful social degradation.

Strangely enough, psychogenic pain as an isolated symptom of conversion hysteria is not very common. When it does occur it as often as not covers an underlying encapsulated psychosis. I well remember at the Cassel Hospital treating a man for the single symptom of agonizing pain in the tongue. I was successful in abolishing his pain by analytical methods, and patted myself on the back for my psychotherapeutic skill. I was less complacent when I heard that three months after he left hospital as a "cured" patient he committed suicide in a state of galloping involutional melancholia. Neurologists not uncommonly come across cases of psychogenic trigeminal neuralgia, and the patients have at one time or another been treated by injection of the Gasserian ganglion. In my experience it is often wiser to allow these people to continue with their pain rather than to seek to remove it by analytical psychotherapy. Some people require a hair shirt or need to go through life with peas in their shoes.

Another complication of pain, regarded from its psychic aspect, is that the differentiation between pleasurable and painful stimuli is very indeterminate and variable, and that the point where pleasure passes over into pain (and vice versa) is therefore by no means constant. When the pleasure taken in pain is sexually tinged, even though the sexual factor is repressed and hence unconscious, the term "masochism" is applied. Persons endowed with an asthenic attitude to life—usually schizothymes—are more inclined to exhibit masochistic tendencies; persons with sthenic temperamental attributes are potentially more sadistic.

We can see, then, that pain of purely central origin can perform two sets of psychobiological functions: (1) regulate the balance between guilt and innocence by (unconsciously) self-imposed punishment, and (2) satisfy the conflicting claims of the masochistic and sadistic components of the personality-structure. From this it follows, as has already been inferred, that by no means all cases of psychogenic pain respond well or should be submitted to psycho-analysis.

The persistence of psychogenic pain or the psychically determined perpetuation of pain that was originally somatogenic not infrequently covers an already established drug addiction. In other words, people stick to their pains in order to provide a subjective justification for continuing to take the drug to which they have become habituated. This consideration should make every doctor very cautious in prescribing analgesic drugs. Pethidine, it will be remembered, was ushered in with a great flourish of trumpets on the grounds that it was non-habit-forming. A few months later, reports were coming in of grave pethidine addiction. Our attitude to pain is for the most part ambivalent; we wish to suffer (unconsciously, it is true), and at the same time we jib at pain and seek to avoid it. This ability to have one's cake and eat it is well shown in states of religious ecstasy—e.g., in the case of dancing dervishes who cut themselves with knives—when self-injury is accompanied by analgesia.

It must be remembered that many pains which are primarily psychogenic are secondarily somatogenic. For example, the colic associated with spastic colon is innervated in the usual way through the autonomic nervous system, although the spasticity of the colon itself may be psychically determined. The pain associated with nervous dyspepsia is another example; and there are innumerable others. It is for that reason that there is no incongruity in or scientific objection to treating these states pharmacologically as well as psychologically at one and the same time.

Two Other Factors

There are two more psychological factors which ought, perhaps, to be considered in connexion with the psychology of pain: (1) the influence of the pattern of culture, in the anthropological sense, on pain tolerance, and (2) individual differences. In many cultures—North-American Indian, for instance—the ability to bear pain without psychomotor expressions of suffering is regarded as an essential virile quality; and it would seem that in days gone by few males failed to pass the test. Among primitive peoples most initiation ceremonies for young boys include the infliction of pain, such as circumcision without an anaesthetic; and the boys are not allowed even to whimper. It would appear, too, that the Russians and the Chinese are traditionally somewhat insensitive to pain and suffering of all kinds.

The converse is equally true: certain patterns of culture permit psychomotor extravagance in the presence of pain. This is true, I think, of Jewish and Latin peoples. This in no way implies a characterological weakness in the individual, who is acting in accordance with his traditional reaction-pattern. I have already inferred that an individual's personality-structure determines his attitude to pain. Evidence of individual differences is also provided by the study of the psychoses.

I remember one schizophrenic boy who attempted suicide in the most bizarre and painful way: he procured a pound of meat (it was in the days when meat was unrationed), let it rot until it stank, expressed the juice, and injected it into his liver with a large, blunt, rusty hypodermic needle. When I questioned him after the long and painful illness which followed he denied that he had experienced anything unpleasant, although his pre-psychotic temperament had been hyperaesthetic. In depressive psychosis physical pain is often welcomed as a counter-stimulus to mental anguish; and manic patients are often so insensitive to pain that they have to be protected from injuring themselves just for the fun of the thing.

Hypnosis

Paradoxically enough, psychiatry has more to offer in the alleviation of physical suffering than in the treatment of psychogenic pain. Pre-frontal leucotomy as a means of abolishing the emotional factor of the pain experience has already been mentioned; and I do not propose in the limited space at my disposal to discuss the advantages and disadvantages of this procedure. It is to the much-neglected practice of hypnosis that I would turn your attention.

The treatment of the psychoneuroses by hypnotism had no sooner come into its own than it was eclipsed by Freudian psycho-analysis and allied methods of therapeutic procedure. And yet hypnotism still has much to offer, especially in the treatment of pain. In my student days there was a boy in hospital suffering from severe osteomyelitis whose daily dressings were so painful that he required a general anaesthetic on every occasion. I obtained permission to hypnotize him, and found that he was susceptible to deep hypnosis. Afterwards he had painless dressings daily under hypnosis.

It is, however, to Salter's work in America that we must look for further advances, provided, of course, that his work can be confirmed and repeated at will. Salter (1944) rejects the views of the psycho-analysts, who regard hypnosis as an artificially induced hysteria, and who suppose that the hypnotist must be unconsciously identified with one or other of the parental figures and that the hypnotized person automatically regresses to a state of infantile dependence.

According to Salter the hypnotic trance itself and all hypnotic and post-hypnotic phenomena are nothing more than conditioned reflexes, and he builds up a very strong case to support this thesis. If Salter is right the hypnotist's "*suggestions*" are to be regarded merely as conditioned stimuli. There is thus no reason why a person should not be trained to provide his own conditioned stimuli, thereby eventually eliminating the need of a "hypnotist" and abolishing the somewhat mystical concept of *rapport*. Salter has, it would seem, elaborated methods of training people in autohypnosis—in other words, self-conditioning—which seem to be sound and relatively simple. He defines autohypnosis as "the ability to induce upon oneself the trance of sleeping hypnosis together with such of its phenomena as may be desired."

The advantages of autohypnosis over heterohypnosis are at once apparent: it is extremely useful for a person to be able at will to abolish existing pain (once its nature has been diagnosed), to cure himself of insomnia, to render himself completely deaf to disturbing noises, to increase his inclination to work, to eliminate stage-fright and other crippling forms of self-consciousness—and all this without having to establish a dependence on any psychologist.

In a world which is becoming increasingly totalitarian, when political-police investigators employ third-degree methods involving physical and mental torture as a matter of course, it may well be that the time has come for all Government "agents" to be trained "autohypnotists." Such an agent, when captured and "investigated," could make himself insensitive to pain of all kinds, could at will be deaf to all sounds, including the sound of his interviewer's voice, could send himself to sleep in all circumstances, and induce amnesia for matters which he did not wish to reveal in such a way as even to circumvent the use of "truth-drugs." It would indeed be extremely difficult, even with the most refined modern methods of "*persuasion*," to extract bogus *confessions from political* opponents.

Disregarding this last rather fanciful and sensational suggestion, it would at least seem that autohypnosis offers some people with intractable pain an easy and legitimate way out of their suffering without the necessity of having their brains pithed.

Salter, Andrew (1944). *What is Hypnosis?* R. H. Smith, New York.

Unesco proposes to publish later in the year a manual on the international exchange of publications. It intends to publish as an annex to this manual a classified list of institutions, including libraries, universities, scientific institutions, learned societies, etc., throughout the world, which are willing to exchange either their own publications or other publications which they have regularly at their disposal. Unesco has obtained a considerable amount of information concerning the availability of exchange material, but considers that it is still far from complete. All institutions which have so far not sent to Unesco details of their exchange material in one form or another are therefore asked to communicate immediately the following information to the Unesco Clearing House for Publications, 19, Avenue Kléber, Paris, 16e: (*a*) Name and full address of institution. (*b*) Exact titles of publications offered. (In the case of duplicates offered for exchange purposes actual lists of duplicates are not required, but only a statement that lists of duplicates are available. Institutions possessing a catalogue of their own publications available for exchange are asked only to send a copy of the catalogue or to give a full bibliographical description of the catalogue.) (*c*) Institutions which wish to exchange their publications only under certain conditions are asked to state what these conditions are. Only information which reaches Unesco before Oct. 1 can be used in the manual.

BANTI'S DISEASE

POSSIBLE RELATIONSHIP TO Rh FACTOR

BY

A. M. NUSSEY, M.D., M.R.C.P.

Physician, Selly Oak Hospital, Birmingham

Clinicians and research workers were quick to grasp the significance of the discovery of the Rh factors, and their combined labours have shed a flood of light on many hitherto perplexing problems. Not a little of the work was done in the Birmingham Children's Hospital, where Sir Leonard Parsons (1933) and his co-workers helped to establish the essential unity of icterus gravis, haemolytic anaemia of the newborn, and hydrops foetalis, and where the subject of kernicterus was investigated. Even before the role of Rh incompatibility in those conditions became known ever-increasing inquiries were being made into the possibility of haemolytic disease being at the root of other

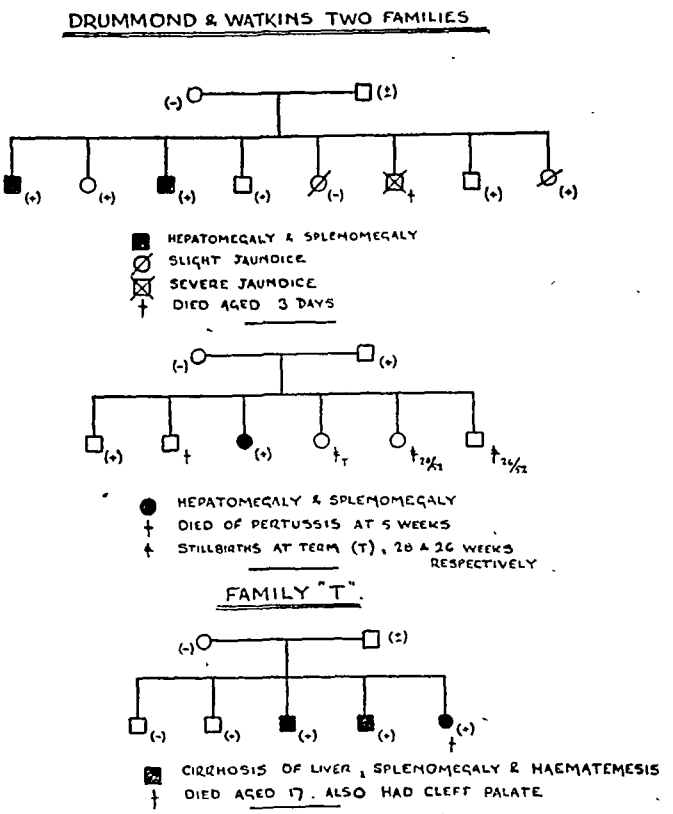

FIG 1 Genealogical tree of Drummond and Watkins's two families and of Family T.

ills which befall mankind, and now they include studies of the genetic make-up of families of imbeciles and mental defectives, those with chorea-athetosis, Wilson's disease, and congenital obliteration of bile ducts, and of some individuals showing enlargement of liver and spleen.

No convincing proof has so far been found that either mental defect in the broad sense or Wilson's disease is caused by Rh incompatibility; but Skelton and Tovey (1945) reported congenital obliteration of the bile ducts in association with haemolytic disease. It is generally known that in severe haemolytic disease of the newborn, in addition to jaundice, there may be an enlargement of liver and spleen, and that this enlargement may persist for some time after the jaundice has subsided. It is therefore natural that when we find young patients with enlargement of the liver and spleen of seemingly unknown aetiology we should ask ourselves whether Rh incompatibility may not have had something to do with it.

No doubt this question has occurred to many clinicians, but, surprisingly enough, only one paper could be found in which an endeavour was made to answer it. Drummond and Watkins (1946) record three families with hepatomegaly and splenomegaly. They make it clear that in only two of these families could the Rh factor have played a part, and for the sake of brevity the main details of these are summarized here in the form of family trees (Fig. 1). Drummond and Watkins state that in neither of their families did the mother have a transfusion, and one is struck straight away by the fact of the firstborn being affected in No. 1 family, while the disease, after skipping the next Rh-positive child, caused the same condition in the third one, and thereafter was probably responsible only for the death of the sixth child. Family No. 2 conforms more with our conception of how Rh incompatibility works—the first one or two, in this case two children, being responsible for sensitizing the mother and seemingly escaping, while those who follow bear the brunt of the disease. In both these families the mothers had no Rh antibodies when examined, but suffered severe reactions when transfused with 50 ml. of Rh-positive ABO compatible blood, and subsequently showed abundant Rh antibodies.

Details of Family T.

In the family about to be described the possibility of Rh incompatibility playing a part in the incidence of hepatomegaly and splenomegaly stands out even more clearly. The genetic make-up of the family for the various blood groups is set out in the accompanying table.

Table Showing the Various Blood Groups of Family T.

Name	Age	Group	Antisera				Rh Genotype	M	N	P
			C	D	E	c				
Father ..	52	A	+	+	−	+	CDe/cde	+	+	−
Mother ..	51	A	−	−	−	+	cde/cde	−	+	+
Arthur ..	28	A	−	−	−	+	cde/cde	+	+	+
John ..	26	O	+	+	−	+	CDe/cde	+	+	+
Frank ..	23	A	+	+	−	+	CDe/cde	+	+	+
Edward ..	19½	A	+	+	−	+	CDe/cde	+	+	+
Kathleen ..	17	A	+	+	−	+	CDe/cde	+	+	+

Here, then, an Rh-negative woman, who had never had a transfusion, married a heterozygous Rh-positive man and had five children. The parents, who have been examined, are normal clinically. The first child of the marriage, Arthur (28), who is Rh-negative, is perfectly normal. The next one, John (26), is Rh-positive, and he too is normal, which is quite understandable considering he must have been the first in a position to sensitize his mother against the D antigen. The next three children, all Rh-positive, revealed enlarged spleens and palpable livers, and their more detailed history is as follows.

Case 1

Frank, now aged 23, was sent to the Children's Hospital, Birmingham, in 1936 on account of abdominal discomfort. There his liver was found to be moderately enlarged, firm, and smooth, and his spleen very large. Liver-function tests were within normal limits, he was not anaemic, and his white blood count was normal—8,000 (71% polymorphs, 1% eosinophils, 1% basophils, 14% lymphocytes, 13% monocytes).

A diagnosis of Banti's disease was made, and later in the same year he was readmitted for splenectomy. Dr. H. S. Baar very kindly looked out the original sections of the spleen, and his comment on them and on those of the other two affected sibs is that they are typical of Banti's disease.

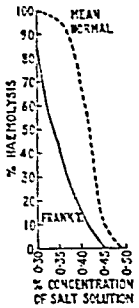

FIG. 2.—Graph showing decreased fragility of red cells in Case 1.

This lad remained well for over a year after the splenectomy, and early in 1938 he was admitted to this hospital following his first haematemesis. A second haematemesis at the end of 1938 necessitated a blood transfusion. In all he was admitted on ten occasions because of haematemeses, the last one being in April, 1949. At no time, however, was his condition really desperate, and transfusion had to be carried out on only three other occasions. Liver-function tests which were repeated here showed no evidence of serious dysfunction.

Examination of his blood and urine did not point to any excessive haemolysis, and in fact there was a small but significant decrease in the fragility of the red cells (Fig. 2), a point also noted by Drummond and Watkins (1946) in their patients. His white cell and platelet counts were within normal limits, too. This patient's liver is now only just palpable and he himself is reasonably well and earning a living as a bakelite moulder.

Case 2

Edward, now 19½, was brought to this hospital in August, 1938, following his first haematemesis. His spleen was appreciably enlarged, while the liver exceeded the normal limit only slightly. Again Banti's disease was diagnosed. This boy's bleeding and clotting times and his white cell count were normal. In September, 1938, Mr. James Gore performed a splenectomy on him; recovery was uneventful. The pathologist's report states: "The spleen shows fibrosis extending through the organ, slight thickening of capsule, and dilated sinuses. Hyaline swelling present in endothelial layers of the vessels of the Malpighian bodies."

Fifteen months after splenectomy this patient had a further haematemesis, and by July, 1948, he had had eight haematemeses in all. He also showed remarkable recuperative powers, though at one time in 1945 his condition was critical. His liver-function tests were normal, too, and he showed no evidence of excessive blood destruction.

Case 3

I saw Kathleen, the fifth child, for the first time in October, 1947, when her brother Frank was an in-patient with haematemesis. It was then that I began to make tentative inquiries into the possibility that we were dealing here with a familial affection due to Rh incompatibility. Clinical examination of the girl revealed an enlarged spleen and a cleft palate but no anaemia. Till then she had never had any overt bleeding, and although somewhat delicate was able to work as a box-maker.

She was not seen again till June 27, 1948, when she was brought into hospital as an emergency case following haematemesis. Her blood count showed 8.4 g. % Hb, 3,220,000 red cells, 5,100 white cells, with 64% polymorphs. At first her condition did not give rise to anxiety, but on July 2 she rapidly became very ill following a severe melaena and haematemesis. There was a temporary rally after a transfusion of 3 pints (1.7 litres) of blood, but next day she collapsed again and became almost moribund. A further 3½ pints (2 litres) of blood was given, but profuse melaena continued and she died on July 4.

Post-mortem examination showed varices at the cardio-oesophageal junction, and on the greater curvature of the stomach about 1 in. (2.5 cm.) from the cardiac sphincter an acute ulcer which had eroded one of the dilated veins. The mucosa round the ulcer was injected, but, apart from this and much altered blood in the small intestine, no other abnormality was found in the gut. The spleen, which weighed 13¼ oz. (383 g.) and was about 6 in. (15 cm.) long, contained localized patches of fibrosis in the capsule, and was partly adherent to the diaphragm. Its pulp was beefy and showed an increase in fibrous tissue. The liver, which weighed 45 oz. (1,276 g.), had a finely granular surface. It showed great increase in fibrous tissue, grey strands of which were visible to the naked eye. Sections of the liver and spleen are shown

FIG. 3.—Section of liver in Case 3, showing cirrhosis.

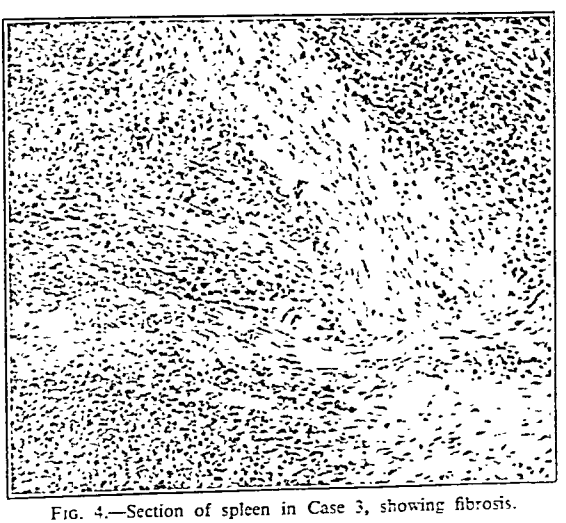

FIG. 4.—Section of spleen in Case 3, showing fibrosis.

in Figs. 3 and 4. No other gross abnormalities were found, and in particular the basal ganglia of the brain showed no degenerative changes.

Discussion

The parents in our family never noticed any jaundice in their children either at birth or subsequently. This is in conformity with the findings in the cases of Drummond and Watkins (1946), and does not, of course, rule out the possibility that a considerable degree of neonatal anaemia may have been present in these patients. In this connexion it is worth recalling the statement by Vaughan (1946), who found no correlation between the incidence of kernicterus and the degree of blood destruction—in other words, the symptoms we associate with kernicterus may occur in children who have never been jaundiced. This too was

pointed out long ago by Sir Leonard Parsons and his associates.

All this raises the question whether Mollison *et al.* (1948) are right in maintaining that the evils which flow from Rh incompatibility can be put down to the effects of blood destruction or whether the Rh antibody is able to fasten on fixed somatic cells and wreak damage there. Support for the second view is given by Boorman and Dodd (1943), who have shown that the Rh factor is a general characteristic of many tissues, and consequently many if not all tissues are likely to be susceptible to injury by Rh antibodies. The Birmingham school (Baar, 1946) also produced evidence of what we may term primary hepatic damage by Rh antibodies.

Another point of interest is that the mother of our patients showed no Rh antibodies and failed to produce them after an injection of 0.05 ml. of Rh-positive blood obtained from one of her sons, but showed them after injection of 5 ml. of her husband's blood. Something similar was found by Drummond and Watkins (1946), and the assumption is that the antibodies which the mother had originally died out with the passage of time, only to reappear under suitable stimulation. On the other hand, Gerrard (personal communication, 1949) found blocking antibodies in a woman 18 years after she had given birth to a child with icterus gravis. The child concerned died of cirrhosis of the liver at the age of $3\frac{1}{2}$, and the case was reported by Braid and Ebbs (1937).

If, from the fate of my patients, I may be allowed to draw any conclusions about the outlook in similar cases, I may be tempted to say that splenectomy improves the prognosis, but cannot be sure that this is the case when I recall that Frank did not bleed until after his splenectomy, and that Kathleen's death was almost certainly the result of a fortuitous gastric erosion superimposed on a dilated vein. Whitby and Britton (1946), however, are of the opinion that splenectomy influences the prognosis favourably. It may be that in future instead of a simple splenectomy some form of porto-caval anastomosis will be undertaken in similar cases.

The three patients described, though they showed no leucopenia or progressive anaemia, would qualify for inclusion in the so-called Banti's syndrome. What Banti (1894, 1910) had in mind when he described the disease to which he gave his name is not absolutely plain, and subsequent commentaries have not helped to clarify the issue. It has been obvious for some time, however, that the name Banti's syndrome has been used as a cloak for a variety of diseases. It may be that further work will sort out one of the entities lumped together under the title of Banti's disease by confirming that fibrosis of the spleen and liver, with enlargement of these organs, and especially of the former, occurring in the young and young adults and accompanied by a tendency to haematemesis, is at times due to Rh incompatibility.

Summary

A family is reported in which three out of five sibs were affected with hepatomegaly and splenomegaly and a tendency to haematemesis.

Reasons are given why this may have been caused by Rh incompatibility.

It is suggested that the condition observed may eventually be segregated from the Banti syndrome.

Grateful thanks are due to Dr. W. Weiner, Director of the Midland Region Blood Transfusion Service, for details of the table setting out the various blood groups of family T. and for his helpful advice; and to Dr. H. S. Baar for his opinion on the pathological sections.

MIKULICZ'S SYNDROME

BY

ALAN J. HIRD, B.Sc., M.B., Ch.B., M.R.C.P.

(From the Gardiner Institute of Medicine, University of Glasgow)

A considerable number of cases of combined lacrimal and salivary glandular enlargement have been reported since Mikulicz (1888) first described the syndrome which now bears his name. Nevertheless the condition is rare enough to prompt the recording of a recent case seen in the Western Infirmary, Glasgow. Since this hospital was opened in 1873 there apparently have been only two other in-patients in whom this diagnosis has been made, both in 1936. On fuller investigation, however, it seems that neither showed enlargement of the lacrimal glands, and their cases can hardly be considered to fall into this syndrome. One was a boy aged 7 with acute myeloid leukaemia and moderate enlargement of the salivary glands, and the other a man of 26 who had bilateral parotid enlargement but no other abnormality. It would seem, therefore, that this is the first case of Mikulicz's syndrome to be seen, at any rate as an in-patient, in the Western Infirmary in 75 years.

Case Report

The patient, a man aged 73, was admitted for the first time on Sept. 30, 1947, complaining of swellings in front of both ears, under the lower jaw, and above both eyes. These had appeared gradually over a period of 12 months, and for a month before admission vision had been much impaired by the presence of the large supraorbital swellings. Apart from these swellings there was no complaint, and the patient had given up his job as a forester only on account of difficulty in seeing. He could remember no previous illnesses. Both parents died when over 90, and all siblings had survived to similar ages.

Examination revealed a well-built healthy-looking man. The most striking abnormality was the symmetrical enlargement of all salivary and both lacrimal glands (Fig. 1). Chemosis of the conjunctivae of both upper lids was present, but neither xerophthalmia nor xerostomia was a feature. In addition there was generalized enlargement of all groups of

FIG. 1.—Appearance on Oct. 6, 1947—before treatment.

superficial lymph glands and also of those of the mediastinum as shown on *x*-ray examination of the chest. The superficial glands ranged up to ¼ in. (1.25 cm.) in diameter and were moderately firm, mobile, discrete, and painless. The spleen was enlarged to 4 in. (10 cm.) below the costal margin.

Blood examination (see Table) showed normal values for haemoglobin, erythrocytes, and total leucocytes, but a neutropenia and lymphocytosis were features of the differential count

Table of Blood Findings

Date	Hb (g.%)	P.C.V. (%)	R.B.C. (10^6)	W.B.C.	Neut. (%)	Eos. (%)	Bas. (%)	Lymph. (%)	Mon. (%)

before treatment. Sternal-marrow examination revealed normal erythroid and myeloid series with possibly a slight increase in lymphocytes. The Wassermann reaction was negative. The erythrocyte sedimentation rate was never more than 5 mm. in one hour by Wintrobe's method. Plasma protein levels were albumin 4.04 g. %, globulin 1.81 g., and fibrinogen 0.47 g.

A lymph-gland biopsy was carried out and Professor D. F. Cappell reported as follows: "The lymph node shows general overrunning of the architecture with small lymphocytes, which infiltrate the capsule and extend from the hilum into the surrounding fat. Only traces of a follicular structure are identifiable. The condition is one of the ill-defined systematized lymphoid hyperplasias. The association with lacrimal and parotid enlargement suggests Mikulicz's disease, of which the lymphoid form is one variety. It would not be surprising if this condition terminated with lymphatic leukaemia."

Following this report an attempt was made to alleviate the patient's main symptoms by deep *x*-ray therapy, applied both generally and locally. Within a fortnight of beginning treatment there was obvious diminution in the size of the salivary and lacrimal glands and to a smaller extent of the cervical lymph glands. By Nov. 29 there was very pronounced regression of salivary (especially parotid) and lacrimal glands, but the spleen and lymph glands were not greatly altered. The patient was discharged at this time.

When seen again on Feb. 6, 1948, he looked and felt extremely well. Lacrimal and parotid glands were no longer visibly enlarged (Fig. 2). The submandibular glands were still palpable and the spleen and lymph glands unchanged. Blood examination showed essentially normal values, the previously noted lymphocytosis having disappeared.

FIG. 2.—Appearance on Feb. 6, 1948—three months after first course of treatment.

The patient was seen again on April 12; there was then moderate recurrence of the swelling of both lacrimal and submandibular glands. Neither parotid was palpably enlarged and the condition of lymph glands and spleen was unaltered. Blood examination showed a slight fall in haemoglobin and a return of the lymphocytosis, although the total white count remained normal. A further sternal-marrow examination, however, showed gross infiltration with lymphocytes, which comprised about 90% of the total nucleated count. *X*-ray therapy was reinstituted on April 14, and a month later complete regression of lacrimal and submandibular glands had taken place, but other findings, including the leucocyte picture, remained unchanged.

By Aug. 17 there had been sufficient recurrence of the lacrimal swellings to cause difficulty in seeing, and the patient was readmitted. An interesting feature on this admission was the presence of considerable swellings in both lower eyelids, presumably consisting of lymphoid tissue. These swellings were some distance from the free margin of the lids and appeared to be close under the skin; they were certainly not connected with the tarsal glands. Parotid glands were visible and palpable but not grossly enlarged. The submandibular glands could not be felt. Lymph glands generally were still enlarged and the spleen now reached 6 in. (15 cm.) below the costal margin. Otherwise there was no change and the patient felt and looked well. Blood examination showed values for haemoglobin, red cells, and total white cells to be still within normal limits, though the differential white count showed a persistence of the lymphocytosis and neutropenia that had been a feature of previous examinations. A further sternal-marrow film showed the presence of large numbers of lymphocytes, comprising some 95% of the total nucleated cells.

Further local *x*-ray therapy resulted in rapid regression of the swellings around the eyes, but the lymphocytosis persisted. It may be remarked here that the only occasion on which this latter feature was modified by treatment was during the initial course of *x*-ray therapy, when the whole body was irradiated.

The patient was discharged to his home on Aug. 26, and thereafter his general condition seems to have deteriorated fairly rapidly. He was confined to bed from mid-September and died on Sept. 27. His practitioner, Dr. W. D. McLellan, wrote to say that the lacrimal and parotid glands remained of normal size, but there was a rapid and enormous increase in the size of the spleen, which became very tender. Cough and a blood-stained sputum became troublesome symptoms, and there were signs of an increase in size of the mediastinal glands, with collapse of the left lung and a pleural effusion. Blood examination could not be made and a post-mortem examination was not possible; it cannot therefore be said with any certainty that he developed a terminal leukaemic phase, but such an event seems not improbable.

Discussion

Various classifications of Mikulicz's syndrome have been proposed, notably those of Howard (1909), Thursfield (1914), and Schaffer and Jacobsen (1927). Howard's classification, based on four personal and 51 reported cases, has the merit of simplicity, all cases being divided into three groups: (1) Mikulicz's disease proper, (2) pseudo-leukaemia, and (3) frank leukaemia. Thursfield, who described only one case, made an intensive study of the literature and put forward a scheme differing somewhat from Howard's and including tuberculosis, syphilis, and gout as aetiological agents. Schaffer and Jacobsen, with personal experience of ten cases, proposed a classification into Mikulicz's disease (familial and acquired) and Mikulicz's syndrome (due to leukaemia, tuberculosis, syphilis, lymphosarcoma, toxic agents, gout, and other diseases).

The study of these and numerous other papers reporting solitary examples leads to the conclusion that Mikulicz's syndrome is a manifestation of a general involvement of lymphoid tissue rather than a disease of the lacrimal and salivary glands themselves. The involvement may be due to lymphatic leukaemia, but in many cases, as in the present one, there has been only a moderate lymphocytosis in the blood or no deviation at all from normal. It would appear likely that many of these will eventually develop the full picture of chronic lymphatic leukaemia. In the present case, despite the development of a grossly abnormal marrow picture, the peripheral blood showed only a slight absolute lymphocytosis even after a course of at least two years.

Many, if not all, examples of this syndrome described in the past as being due to tuberculosis (e.g., Garland and Thompson, 1933) would probably now be classified as examples of sarcoidosis, while a study of the clinical features of those ascribed to syphilis leaves the impression that in many the syphilitic state may have been purely coincidental. Why Mikulicz's syndrome should be so rare when the pathological states which give rise to it are relatively so common does not appear to have been explained.

Summary

A record is presented of the findings in a case of Mikulicz's syndrome (enlargement of lacrimal and salivary glands) followed from the initial hospital admission until death 14 months later. Many of the features of chronic lymphatic leukaemia, including lymphocytic infiltration of the sternal marrow, were present, but the total leucocyte count was not raised during the period of hospital observation. Swelling of the lacrimal and salivary glands was treated by *x*-ray therapy with satisfactory though temporary results.

Brief reference is made to the more important literature on the subject.

I should like to express my thanks to Professor J. W. McNee, in whose wards the patient was investigated and treated, for permission to publish this account, to Professor D. F. Cappell for permission to include his report on the gland section, and to Miss M. M. Todd for the photographs.

A SIMPLE EMERGENCY METHOD FOR ESTIMATION OF BLOOD SUGAR*

BY

A. L. LATNER, M.D., M.Sc., D.I.C., A.R.C.S.

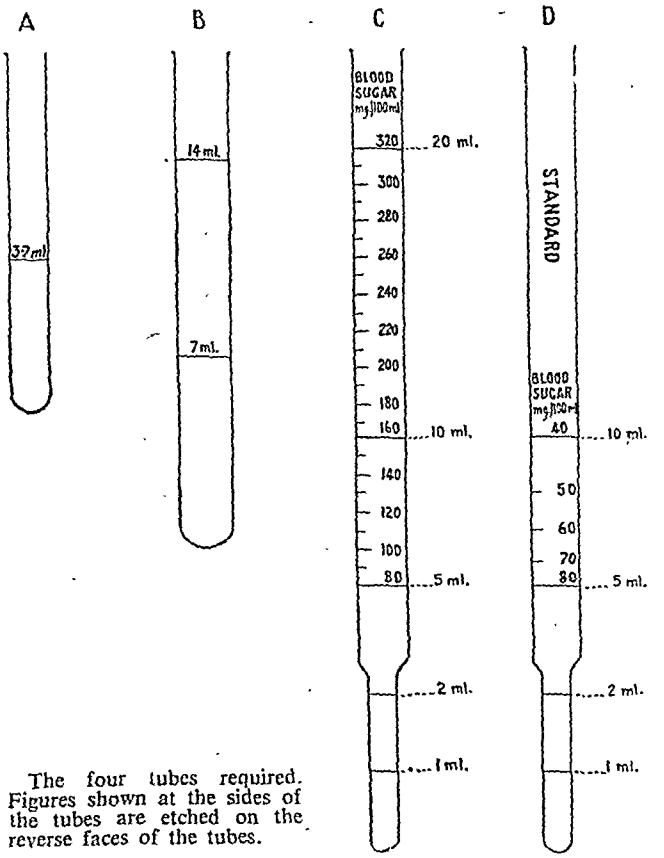
AND

G. B. PENDLENTON, F.I.M.L.T.

(From the Section of Chemical Pathology, Department of Pathology, King's College, Newcastle-upon-Tyne)

A simple and accurate method for estimating blood sugar, either in the ward or in the patient's home, has long been required. The technique of Haslewood and Strookman (1939) as described by King (1946), when used in conjunction with some simple apparatus we have designed, would seem to satisfy these criteria. This apparatus can easily be made by any competent glass-blower. No colorimeter or photometer is necessary.

Apparatus



The following apparatus is required: (1) a number of clean and dry teat-end pipettes; (2) one blood pipette calibrated to contain 0.1 ml., for measuring the blood sample; (3) one pipette calibrated to contain 0.2 ml., for measuring the solution of 10% w/v sodium tungstate; (4) a 1-in. (2.5-cm.) glass funnel and a supply of 5.5-cm. Whatman No. 41 filter papers; and (5) four tubes as shown in the accompanying diagram.

Tube A has an internal diameter of approximately 10 mm. and is calibrated to contain 3.7 ml. It is fitted with a rubber bung.

*Received Jan. 3, 1949.

Tube B has an internal diameter of approximately 13 mm. and is calibrated to contain 7 ml. at the lower mark and 14 ml. at the upper. It is fitted with a rubber bung.

Tube C has a narrow portion approximately 5 cm. long with an internal diameter of approximately 8 *mm.*, and a wider portion approximately 16 cm. long with an internal diameter of approximately 13 mm. It is calibrated by ring markings to contain 1, 2, 5, 10, and 20 ml. The length between the 5- and 20-ml. calibrations is further subdivided into 24 equal portions by alternate short and long etched lines. The long lines from below upwards are marked 100,

The four tubes required. Figures shown at the sides of the tubes are etched on the reverse faces of the tubes.

120, 140, and so on up to 320, which coincides with the 20 ml. mark. These markings represent mg. of glucose per 100 ml. of blood.

Tube D is similar to tube C and of identical measurements. It also has ring calibrations at 1, 2, 5, and 10 ml., the length between its last two markings being subdivided into four portions. These are determined by adding calculated volumes of water, namely:

At calibration	70	the tube contains a total volume of	5.7	ml.
,,	,,	60	,,	,,	,,	,,	,, 6.7	ml.
,,	,,	50	,,	,,	,,	,,	,, 8	ml.
,,	,,	40	,,	,,	,,	,,	,, 10	ml.

Solutions Required.—These are exactly as described by King (1946). The standard solution contains 2 mg. of glucose per 100 ml. and is prepared fortnightly by suitably diluting the stock solution containing 0.1 g. of glucose per 100 ml. with saturated benzoic acid.

Method

Tube A is filled to the mark with the isotonic sodium-sulphate–copper-sulphate mixture by means of a teat-end pipette. Blood obtained by capillary puncture is collected in a tube of internal diameter about 8 mm., which contains a small quantity of neutral potassium oxalate to prevent coagulation.

The 0.1-ml. blood pipette is filled to the mark with this blood and the outside of the pipette carefully wiped free of blood with clean cotton-wool. The measured quantity of blood is delivered into the solution in tube A and the inside of the pipette rinsed into the solution by sucking some of the fluid into the pipette up to the mark and then blowing it back again. This is repeated twice. Tube A is gently shaken to ensure thorough mixing, and 0.2 ml. of 10% sodium tungstate is added. The tube is closed with a rubber bung and inverted several times to get thorough mixing. After standing a few minutes the precipitate which forms is filtered off through a dry 5.5-cm. No. 41 Whatman filter paper. Tube C is filled to the 1-ml. mark with this protein-free blood filtrate and tube D to the same mark with the standard glucose solution. For each of these manipulations separate teat-end pipettes are used which are long enough to deliver direct into the narrow ends of the tubes.

The alkaline copper solution is now prepared by filling tube B to the lower mark with solution A and adding solution B to the upper mark. Again teat-end pipettes are used. The tube is closed with a rubber bung and shaken well to ensure mixing. Tubes C and D are further filled to the 2-ml. mark with the alkaline copper solution so prepared, using a clean teat-end pipette. The tubes are carefully shaken to ensure thorough mixing, are placed in boiling water for exactly 10 minutes, and then rapidly cooled by immersion in a relatively large volume of cold water or under the tap. Both tubes are filled with the phosphomolybdic reagent exactly to the 5-ml. mark, the open end is closed by the thumb, and the contents are mixed by inversion. The small amount of fluid adhering to the thumb is restored to the tube by wiping the thumb across its edge.

If the blood sugar is above 80 mg. per 100 ml. the blue colour in the wide portion of tube C below the 5-ml. mark will be darker than that in tube D. In this event small quantities of distilled water are added to tube C and the contents mixed by inversion after each addition, using the thumb technique already described. When the two colours match, the level of the bottom of the meniscus in tube C indicates the blood sugar. If the level has reached the top mark (320 mg. per 100 ml.) and the colour in tube C is still darker than that in tube D, the former tube is emptied exactly to the 10-ml. mark and further diluted until correct matching is obtained. In this case the final reading obtained must be doubled in order to give the correct blood sugar. In this way values up to 640 mg. per 100 ml. of blood can be determined. For higher levels the tube is again emptied to the 10-ml. mark and the final reading multiplied by four.

If the original blue colour in tube C is lighter than in tube D the blood sugar is less than 80 mg. per 100 ml. It can be determined by suitably diluting the fluid in tube D until the colours match and reading the calibrations on this tube.

Results

The accuracy of the method has been tested by the usual procedure of recovering known amounts of glucose added to blood, the blood sugar being determined before and after the addition. The results, shown in Table I, can be seen to be remarkably good.

The method has also been used on a number of blood samples by a medical graduate with no special chemical training. All matching was done by artificial light in order to simulate ward emergency conditions, as, for example, in the diagnosis and treatment of a patient in a diabetic coma admitted at night. A parallel series of determinations was also carried out by a trained laboratory technician, using the method of Herbert and Bourne (1930). The results are shown in Table II. The findings speak for themselves.

TABLE I.—*Recovery of Glucose Added to Blood*

Blood Sugar (mg. per 100 ml.)	Added Glucose (mg. per 100 ml.)	Calculated Total	Found	% Error
85	100	185	185	0
85	200	285	290	+2
85	300	385	380	−1
85	400	485	500	+3
70	100	170	170	0
70	200	270	260	−4
70	300	370	380	+3
70	400	470	450	−4
120	100	220	240	+9
120	200	320	340	+6
120	300	420	420	0
120	400	520	490	−6
65	100	165	165	0
65	200	265	255	−4
65	300	365	390	+7
65	400	465	480	+3

TABLE II.—*Comparison with Laboratory Findings*

Blood Sugar (mg. per 100 ml.)		Blood Sugar (mg. per 100 ml.)	
Emergency Method	Laboratory Method	Emergency Method	Laboratory Method
107	120	115	125
104	115	140	140
195	190	70	70
110	120	250	280
70	85	240	260
120	135	235	250
159	180	70	65
210	210	240	220
225	220	400	420

A sufficient degree of accuracy for most clinical requirements could no doubt be obtained by the provision of a dropping pipette which delivers 0.1 ml. of blood in a known number of drops. This, in conjunction with a similar method for delivering the sodium tungstate, would simplify the method still further.

Summary

With the use of easily constructed apparatus the method of Haslewood and Strookman has been converted to a simple dilution technique, requiring neither colorimeter nor photometer.

Estimations have proved accurate in the hands of a medical graduate with no special training in biochemical methods.

We wish to thank Dr. W Jack, who carried out the determinations in Table II.

The housing progress summary for May, presented to Parliament as a White Paper (Cmd. 7723), shows that the number of permanent houses completed in Great Britain during May was 16,866, compared with 15,110 in April. This brings the number of permanent houses completed during 1949 to date to 84,688. The total number of houses completed since the war is 667,656 (510,408 permanent and 157,248 temporary). Of the permanent houses, 379,016 were built by local authorities and 86,492 by private enterprise. During May homes were provided by new building, repair of uninhabitable houses, conversion, and requisitioning for 18,469 families, compared with 16,587 in April. This brings the total number of families rehoused by these methods under the post-war programme to 957,113.

METHYL N-PROPYL ETHER

BY

C. E. SYKES, M.B., F.F.A.R.C.S.
Anaesthetist, Manchester Royal Infirmary

Methyl n-propyl ether, known also as "metopryl," is a clear, colourless, volatile liquid having a characteristic smell which is not unpleasant. It has the chemical formula of

and is isomeric with diethyl ether and isopropyl-methyl ether (isopryl). Methyl n-propyl ether was first used as an inhalational anaesthetic on the human subject on Oct. 3, 1945, at the South Baltimore General Hospital for appendicectomy and uterine suspension.

Carr *et al.* (1947) give the following information concerning these ethers:

TABLE I

	Diethyl Ether	Metopryl	Isopryl
Boiling-point	35° C.	39° C.	31° C.
Solubility in water (ml. in 100 ml. at 25° C.)	8·6	5·0	9·9
Oil/water coefficient	4 ± 0·4	10 ± 1	2 ± 0·2

The inflammability range is identical with that of diethyl ether (White *et al.*, 1946). The specific gravity is 0.726 at 16° C.

In their series of cases White *et al.* found that, compared with diethyl ether, methyl n-propyl ether was less irritating to the respiratory tract, the pulse rate was not as rapid, the blood pressure rose and returned to normal more quickly, and muscular relaxation was more easily achieved. Post-operative nausea and vomiting were less and there were no pulmonary complications. The physical signs of varying depths of anaesthesia do not vary greatly from Guedel's classification. They also found that the potency of methyl n-propyl ether when measured on the dog is approximately 25% greater than that of diethyl ether.

Fisher and Whitacre (1947) from a series of 500 cases concluded that decreased irritation of the respiratory tract is the drug's only advantage over diethyl ether.

Krantz *et al.* (1947) consider that methyl n-propyl ether has a wider margin of safety than diethyl ether. They state that if it be assumed that to induce anaesthesia with diethyl ether the volume per kg. of body weight is 1 ml., and to produce respiratory arrest the volume per kg. is 2 ml., the corresponding volumes of methyl n-propyl ether are 0.84 and 2.1 ml. Therefore methyl n-propyl ether has a higher potency but a wider margin of safety than diethyl ether. Rochberg (1947) showed that in 86 cases 52.8% had nausea or vomiting.

Clinical Trial

I obtained a small amount of methyl n-propyl ether for clinical trial, though the scarcity of the drug made it impossible to carry out the investigation on as large a scale as one would have wished. Table II shows the list of cases included in the series. In all except Cases 16, 17, and 18 the ether was placed in the ether container of a Mushin closed-circuit apparatus, while in those three instances the ether was placed in the chloroform bottle of the Boyle apparatus.

In my hands the induction period was not much shorter than with diethyl ether, though, contrary to expectations, it was shorter in those cases in which the ether was in the chloroform bottle. Cases 16 and 17 were powerfully built men who settled quickly and quietly. The diminished irritation of the respiratory tract was very noticeable. Relaxation was satisfactory, but not more so than with diethyl ether. The post-operative period was most satisfactory.

TABLE II

Case No.	Sex	Age	Operation	Duration in Minutes	Complications	
					Vomiting	Pulmonary
1	M	53	Partial gastrectomy	125	No	Yes
2	M	19	Trendelenburg operation	37	No	No
3	M	33	Herniorrhaphy	45	No	Yes
4	M	44	For hydrocele	20	No	No
5	F	41	Bilateral cervical sympathectomy	80	No	No
6	F	18	Appendicectomy	25	No	No
7	F	64	Herniorrhaphy	30	No	No
8	F	25	"	60	No	No
9	F	16	"	90	No	No
10	F	17	"	35	Yes	No
11	F	27	"	24	Yes	No
12	F	64	"	15	No	No
13	M	25	Meniscectomy	27	No	No
14	M	29	Reamputation end of fibula	22	No	No
15	F	42	Keller's operation	25	No	No
16	M	41	Removal os calcis spur	15	No	No
17	M	46	Meniscectomy	25	No	No
18	M	42	For dislocated scaphoid	20	No	No
19	F	24	Tonsillectomy	18	No	No
20	F	43	Herniorrhaphy	60	No	No

Case 1 was a nervous man who had a high abdominal incision—the type of case in which pulmonary complications would be expected. Case 3 had a rise in temperature, and on *x*-ray examination was found to have tuberculous cavities in his apices and a positive sputum which had been missed in the pre-operative examination. Cases 10 and 11 each had a slight amount of vomiting on one occasion.

Apart from these cases all patients made an uninterrupted recovery and had no complaints to make about the anaesthetic. Other members of the surgical teams concerned noticed the unusual smell of the methyl n-propyl ether but made no adverse comments. In 10 cases there was a fall in the pulse rate during administration of the anaesthetic, in five a rise and later a fall, in four a rise which did not return to the former level, and in one case a fall which did not return.

Summary

Methyl n-propyl ether is described. The results of a clinical trial of this inhalational anaesthetic in 20 cases are given. The chief points of interest are the lack of irritation of the respiratory tract and the small percentage of post-operative pulmonary and gastric complications.

I wish to express my thanks to Messrs. Duncan, Flockhart and Co for their kindness in providing me with the sample of methyl n-propyl ether used in this test.

The functions of the National Research Development Corporation, which are defined in the Development of Inventions Act, 1948, are to secure, where the public interest requires, the development or exploitation of inventions and to acquire and dispose of rights in connexion with inventions. The President of the Board of Trade has appointed the following members of the corporation: Sir Percy Mills (chairman), the Earl of Halsbury (managing director), Professor P. M. S. Blackett, F.R.S., Sir John McLean Duncanson, Sir Edward H. Hodgson, Mr. W. E. P. Johnson, and Sir Edward de Stein. Correspondence should be addressed to the corporation at I.C. House, Millbank, London, S.W.1 (telephone: Whitehall 5140).

SIGNIFICANCE OF CONVULSIONS IN INFANCY

BY

P. W. NATHAN, M.B., M.R.C.P.
Neurological Research Unit, Medical Research Council, National Hospital, Queen Square

AND

P. M. RANSFORD, M.R.C.S., L.R.C.P., D.C.H.
Supernumerary Registrar, Hospital for Sick Children, Great Ormond Street; Paediatric Registrar, Royal Infirmary, Leicester

There are two opinions about the significance of convulsions in infancy. One is that convulsions within the first two years of life are of no serious significance, that many children have them, and that these children are no more likely than others to have convulsions later in life. This view is often held by parents and general practitioners. Peterman (1939) supports this view, as follows: "The young child is subject to certain hazards and diseases These diseases are characterized by a tendency to produce convulsions. Once these hazards have been safely passed. the child is no more susceptible to seizures than is the adult under similar circumstances." The second opinion is favoured by neurologists. They usually hold that infantile convulsions are the early manifestation of epilepsy. Turner (1907) found in his series of 1,000 epileptics that the greatest number beginning in any single year occurred in the first year of life.

The purpose of this paper is to present some evidence which may contribute to the formation of an opinion on the significance of these convulsions.

Present Investigation

The evidence is based on observations obtained from two groups—a group of 200 patients attending hospital as out-patients on account of epilepsy, and a control group. Each group is subdivided into two according to age—namely, one to contain subjects aged 2 to 15 years, and the other to contain those from 15 to 35. The 100 controls aged 2 to 15 were out-patients at the Hospital for Sick Children or at the Leicester Royal Infirmary, which they were attending for disorders other than epilepsy; the 100 controls from 15 to 35 were acquaintances of one of us (P.W.N.), and included a large number of hospital workers, nurses, technicians, and doctors. The 200 epileptics were out-patients attending the National Hospital on account of this disorder

It will be understood that in the epileptic groups there is selection to the extent that no one is included who has to live in an institution—such as an epileptic colony, an institute for mental defectives, or a mental hospital. The epileptics are those who remain within the normal community, living in their own homes, attending London schools, and working; and those in the control groups are their counterparts, but having no fits. No one was admitted into the control group unless he was able to find out from his parents whether he had had infantile convulsions; also, in the epileptic group the history was always obtained from a parent, who was asked about the occurrence of any convulsions, fits, faints, sudden stiffenings with loss of consciousness, or facial expression of vacant staring.

Of the control subjects, two (2%) in each age group had had infantile convulsions. Of the 100 epileptic subjects from 2 to 15, 34 had had infantile convulsions. and of the 100 from 15 to 35, 14 had had infantile convulsions.

This pronounced difference—2% in the control groups and 14% and 34% in the epileptic groups—makes it clear that convulsions within the first two years of life are to be taken as a manifestation of epilepsy, and that the subject so afflicted is likely to have a recurrence of fits in later years. It also seems that the recurrence is likely to show itself before the fifteenth year. It is of interest that this percentage of those having a recurrence of fits before the age of 15 is so much higher than that of those having a recurrence after the age of 15. This may indicate that the longer the child lives free from convulsions the less likely he is to have any.

The question arises, If convulsions within the first two years of life indicate that the child is an epileptic, should some treatment be started? General neurological opinion holds that the longer the subject remains free from attacks the less likely he is to have further attacks. The lower percentage in the older epileptic group supports this belief. This observation upholds the view that any child having convulsions should be treated with anticonvulsant drugs for a prolonged period, and possibly for years.

Medical Memoranda

Bilateral Hydrosalpinx with Torsion of Both Tubes

Torsion of the Fallopian tube is an uncommon condition, but cases are reported in the literature fairly regularly. Anspach (1912) was able to collect 95 cases, and in 62 of them the lesion of the tube was a hydrosalpinx. Eastman (1927) brought the number of cases of torsion of hydrosalpinx up to 91, and Goldberg and Olim (1938) increased the figure to 108. The condition, therefore, is not excessively rare, but bilateral torsion is extremely uncommon. Anspach records seven instances in his paper, and since then additional cases have been described by Sénéchal (1932), Pineda and Campagnoli (1934), and Ficklen (1938).

CASE REPORT

A nulliparous married woman aged 24 was admitted to the West Middlesex County Hospital on May 31, 1948, complaining of a sharp knife-like pain in the right loin, radiating round to the front of the abdomen and down to the pubes, of twenty-four hours' duration. There had been nausea but no vomiting. Her bowels had been regular and micturition had been normal apart from slight difficulty in initiating the act since the onset of the pain. Her periods took place every 23 days and lasted seven days. She experienced some backache on the first day. Her next period was expected on the day after her admission, and in fact it began that day. She complained of some yellow vaginal discharge which was most pronounced on the two days before the onset of menstruation. Her previous health had been good; she had never experienced a similar attack of pain in the past. She had undergone two minor operations for the correction of a narrow introitus.

On physical examination her temperature was 100° F. (37.8° C.), pulse rate 92, and respirations 20. The tongue had a moist white coat. The abdomen moved fairly [illegible] respiration, and there was slight tenderness and [illegible] in the lower quadrants of the abdomen, greater [illegible] side than on the left. Rectal examination revealed [illegible] of two cystic swellings (or one bilobular swelling)

of Douglas, each about the size of a tangerine and attached to the back of the uterus. They were moderately tender. This finding was confirmed on vaginal examination. The white cells numbered 15,000 per c.mm., of which 77% were polymorphs. A radiograph of the pelvis showed the presence of a cluster of teeth in front of the sacrum and a little to the left of the midline. A diagnosis of twisted or infected dermoid ovarian cyst was made.

Above—the right hydrosalpinx. Below—the left hydrosalpinx with the associated dermoid cyst, opened to show teeth and hair.

Operation.—On June 4 the abdomen was opened through a midline subumbilical incision. The left ovary was replaced by a dermoid cyst the size of a large pear. There was a left hydrosalpinx the size of a hen's egg which had undergone torsion about one and a half times in a clockwise direction. It was blue in colour and had a congested appearance which improved when the torsion was undone. On the right side there was also a hydrosalpinx which had undergone torsion. It was the size of a duck's egg and was purplish red. It was clearly the seat of strangulation. The twist was also about one and a half times in a clockwise direction. The point of torsion was at the junction of the normal and cystic portions of the tube about 1 in. (2.5 cm.) from the cornu of the uterus. At this point the tube was constricted by a narrow omental adhesion. The right ovary was about the normal size, but was studded with small cysts. A left salpingo-oophorectomy and a right salpingectomy were performed, the severed end of the right tube being left open. The appendix was removed and the abdomen closed.

Convalescence after operation was uneventful and the patient returned home on June 17. Her customary menstrual cycle has continued since the operation.

The specimens have been mounted for preservation in the hospital museum, and consequently no histological examination of the tubes has been made.

COMMENT

The left hydrosalpinx was in a state of simple torsion without gross interference with the blood supply, while the right tube had undergone torsion with strangulation, converting the hydrosalpinx into a haematosalpinx. The patient's symptoms were produced by the lesion of the right tube; the twist of the left tube was a coincidental finding. The omental adhesion around the point of torsion of the right tube may have been an important factor in producing the twist by constricting the area of attachment of the hydrosalpinx. The dermoid cyst of the left ovary had not taken part in the torsion of the left tube and did not seem to have had anything to do with its production.

A study of the recorded cases of torsion of the Fallopian tube reveals that in the majority of cases the tube is the seat of disease, although a normal tube may undergo this complication. The commonest lesion is a hydrosalpinx, and this fact is well shown in the figures quoted above from Anspach's paper. A hydrosalpinx satisfies the conditions required for torsion of an organ—namely, a freely mobile tumour attached to a more or less fixed base by a pedicle. A pyosalpinx, on the other hand, is much less likely to undergo torsion because of surrounding adhesions which limit its mobility.

The clinical picture of torsion of the tube resembles that of torsion of an ovarian cyst, for which it has often been mistaken, but differs in that the symptoms are much less severe, and also in that shock is not a feature of the condition.

I wish to thank Mr. John Scholefield, under whose care the patient was admitted, for guidance and for permission to publish this case.

Leiomyosarcoma of the Stomach

Leiomyosarcoma is one of the rarest tumours of the stomach, comprising only 10% of all gastric sarcomas. Ewing (1940) estimated that 1% of malignant tumours of the stomach were sarcomatous. At the Mayo Clinic in one year, however, of 298 malignant lesions of the stomach 3.3% were sarcomas (Counseller *et al.*, 1946). Edwards and Wright (1933) thought the condition more common than the number of reported cases indicated.

CASE REPORT

The patient was a Bantu woman aged 21. She had four years' history of attacks of severe epigastric pain, which was unrelated to meals but worse before her periods. For the last six months she had continuous pain and frequent vomiting, the vomitus being pale and never coffee-ground in appearance. Her appetite was good, but she had lost a great deal of weight and was becoming progressively weaker. Her diet was predominantly carbohydrate, and her home conditions were poor.

On examination she was cachectic and too weak to stand. The temperature was 100° F. (37.8° C.) and pulse 120. In the abdomen a hard, tender mass was felt occupying the costal angle; there was a second mass under the left costal margin which appeared to be connected with the liver. Both masses were felt only on deep inspiration. There were no other physical signs.

The patient stopped vomiting on the day of admission. She exhibited a remittent temperature which frequently reached 102° F. (38.9° C.). A chest radiograph showed clear lung fields but a raised left diaphragm. She was too ill for screening.

The blood count demonstrated a hyperchromic anaemia, with metachromasia and anisocytosis. The r.b.c. was four million, the Hb 77%, and the colour inde[illegible]. The w.b.c. was [illegible] of which 79% were polymorphs [illegible] of the marrow showed a macronormo[illegible] test meal revealed complete abs[illegible] acidity in the resting juice, and

meal. Blood was present in one specimen. The sugar tolerance curve for hepatic function showed a fasting level of 80 mg.% and a rise of blood sugar after 50 g. of dextrose to 200 mg.%, followed by a lagging fall. There was no glycosuria. The E.S.R. was 31 mm./hour (Cutler technique).

Ten days after admission the patient passed a stool consisting of a large amount of red clotted blood. Proctoscopic examination revealed no abnormality. After this haemorrhage the blood count was: r.b.c. 2,400,000, w.b.c. 7,000, Hb 20%, colour index 1.1. The patient was free of abdominal pain, vomiting, and diarrhoea, and felt better, but showed some oedema of the feet. She was given 5 ml. of liver extract intramuscularly daily, and received two blood transfusions of 250 ml. each on successive days. There was no reticulocyte response to the liver therapy after nine days. She became somnolent and died five weeks after admission.

In view of the long history, the macronormoblastic bone marrow, the lower bowel haemorrhage, the oedema, and the macrocytic anaemia which failed to respond to liver, she was considered a case of post-necrotic fibrosis of the liver.

At necropsy a large pedunculated neoplasm, fungating and foul-smelling, was found arising from the lesser curvature and posterior wall of the stomach and infiltrating the left lobe of the liver, which was in contact with it. There were no other deposits in any part of the body. The liver itself was large and fatty. Microscopic examination of the mass revealed it to be a leiomyosarcoma.

I am indebted to Dr. Dormer, medical superintendent of King George V and Springfield Hospitals, for permission to publish this case.

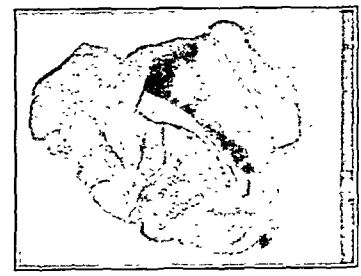
Hydatid Cyst and Cirrhosis

The following is a case of hydatid cyst associated with gross cirrhosis of the liver, an association which has rarely been reported.



CASE REPORT

A woman aged 68 was admitted to Edgware General Hospital on Sept. 27, 1947. She had been well and on holiday until that morning, when she vomited a small quantity of blood; during the day she vomited blood several times, in all about half a pint (284 ml.). She was seen by her doctor about 7.45 p.m. and had difficulty in giving her history, as she seemed dazed. She received an injection of morphine and was transferred to hospital. On arrival at 9 p.m. she was semi-conscious and unable to give any history. Her relatives could add little to the above account except to say that she had had two abdominal operations in early life, the first of these at 13 years, and a third in 1931. The only notes available concerning the last stated: "Laparotomy—hydatid cyst." In 1944 she had a haematemesis from which she entirely recovered. She had lived all her life in Lancashire except for pilgrimages to Lourdes, and she was not an alcoholic.

Examination showed a semi-conscious woman, moderately pale and sweating slightly, who was vomiting blood clot. A few purpuric spots were present on the limbs, and on the abdominal wall there were enlarged veins and two upper abdominal laparotomy scars. The liver edge was 2 in. (5 cm.) below the costal margin; it was smooth and hard, with one large rounded eminence. A firm spleen was palpable 1 in. (2.5 cm.) below the costal margin. She also showed bilateral corneal opacities, depressed tendon reflexes, and a right extensor plantar response. The pulse rate was 110 and blood pressure 100/60. She was afebrile and free from jaundice. There were no other significant findings.

On admission her urine contained protein but was otherwise normal. Blood count showed: haemoglobin, 68%; red blood cells, 3,360,000 per c.mm.; white blood cells, 14,400 per c.mm. *Plasma proteins*: Total, 5.75 g.%; albumin 3.4 g.%, globulin 2.35 g.%. The cerebrospinal fluid was normal in all respects. She was transfused with one litre of blood and 800 ml. of 5% glucose, but failed to improve, and died 36 hours after admission.

Post-mortem Examination (Dr. H. C. Moore).—The body was generally obese. There were large oesophageal varices, and the stomach and intestines contained fresh blood. There was no ascites. The liver weighed 1.95 kg. (normal, 1.2–1.4 kg.) and the right lobe was replaced by a cavity, 18 cm. in diameter, which contained turbid fluid. The walls were composed of a 4-mm. layer of fibrous tissue and compressed liver tissue with a shaggy fibrinous inner surface (see photograph). There was no calcification. The remainder of the liver showed a multilobular cirrhosis with nodules of hyperplastic liver tissue; there were no remnants of other cysts elsewhere in the liver. Gall-bladder and ducts were normal. The spleen was four times its normal size, and firm. Apart from oedema of the lungs there were no other macroscopic abnormalities. Microscopically the liver showed a multilobular cirrhosis. The wall of the cyst consisted of vascular collagenous tissue in which normal bile ducts could still be seen, but no liver parenchyma was present.

The posterior wall of the cyst has been opened; the liver is cirrhotic.

COMMENT

The cause of death appeared to be liver failure due to multilobular cirrhosis, precipitated by a haematemesis from oesophageal varices. Morphine may have slightly hastened death. The large thick-walled cyst which was found at necropsy had existed for many years, and was almost certainly hydatid in origin. Instead of becoming shrunken and calcified after the death of the parasite, as is usual, it had remained distended. Its relationship to the cirrhosis is uncertain.

All authors are agreed on the frequency with which compensatory hyperplasia of the liver cells occurs when part of the liver is destroyed by hydatid disease, but most consider that cirrhosis and hydatid disease occur together merely by coincidence. Dew (1928), for example, states that in view of the great difficulty of excluding other causes it seems that the existence of a true hydatid cirrhosis remains to be proved. A biliary cirrhosis due to obstruction of the bile ducts by hydatid material has been described. It is hard to believe, however, that in the above case multilobular cirrhosis and a thick-walled cyst were present together only by chance. Stevens (1901) described a similar case—that of a man aged 63—in which two cysts were present. Both in his and in my case the cysts had probably existed since childhood, and their great age and survival after the death of the parasite may have had some bearing on the development of cirrhosis.

I am indebted to Dr. G. H. Jennings for his advice and to Miss M. H. Shaw for the photograph.

Reviews

MANUAL OF PUBLIC HEALTH

Hygiene. By J. R. Currie, M.D., Ll.D.Glas., D.P.H.Birm., F.R.C.P.Ed., and A. G. Mearns, M.D., B.Sc.(Public Health), D.P.H.Glas., F.R.S.Ed. Third edition. (Pp. 724; 212 illustrations and 4 plates in colour. £1 15s.) Edinburgh: E. and S. Livingstone. 1948.

This is the second edition since the war of the textbook known affectionately in Scotland as "*Currie and Mearns.*" Rapid changes have occurred since the publication of the 1945 edition, and in bringing the book up to date the authors have considerably enlarged it and greatly increased its value to both undergraduate and postgraduate students. Currie and Mearns has joined the ranks of standard textbooks on both sides of the border, and is by no means confined in its application to Scotland. The book covers the vast domain of public health and hygiene in 26 chapters. The broad picture presented portrays in considerable detail modern public health as a study of the environment and of the community which inhabits that environment. The personal health services are well represented, and the last chapter, entitled "The Social Vista," is an interesting outline of the history of social medicine, including its post-war developments. Great care has been taken with the chapters on food, community diseases, and infestation; personal hygiene and health education are dealt with by an author who has made a special study of these subjects.

It is curious how, even in the most carefully revised textbook, old phrases linger on as though in response to tradition. In chapter 4, for example, it is stated (p. 49) that "main latrines should be placed outside the school building." This is at least a generation out of date. Again, some of the statements about housing and, more particularly, ventilation require reconsideration in the light of recent investigations. In chapter 10 (p. 295) there is over-emphasis on cubic space and consequent under-stressing of the importance of floor area in small houses. Further, it is stated that 8 ft. is too low for a habitable room and that in ordinary houses the height of ceilings may range up to 11 ft. These statements will not stand up to obstinate questioning on grounds of either health or expense.

Nevertheless, the teaching is generally up to date and the subjects are presented in an attractive manner. The paper is excellent for a post-war production, and the book is extensively illustrated with more than 200 well-chosen diagrams, tables, and photographs. It is good to see the return of colour illustrations, which are very effective.

The student of hygiene, and especially candidates for the Certificate and Diploma in Public Health, will find in Currie and Mearns an excellent textbook which gives them all that is required for a well-balanced groundwork. For undergraduates it is easy to read and not difficult for reference. Medical officers of health, sanitary inspectors, and other officers engaged in the practice of preventive medicine are recommended to take it as a refresher course covering the whole field of their work.

J. M. MACKINTOSH.

PUBLIC HEALTH IN THE U.S.A.

Essentials of Public Health. By William P. Shepard, B.S., M.D., M.A. With the collaboration of C. E. Smith, M.D., R. R. Beard, M.D., L. B. Reynolds, A.B., Sc.D. With foreword by R. L. Wilbur, M.D., LL.D., Sc.D. (Pp. 600; illustrated. £1 10s.) Philadelphia and London: J. B. Lippincott Company. 1948.

As the dust-cover states, this book points out the place of the physician in to-day's public health activity and shows clearly where his support is essential. It is written for the practising doctor in the United States; I think it will appeal to a larger public, and that the public health officer in this country will find it stimulating. In the United States much still depends upon voluntary agencies and the enlightenment of public opinion (broadly speaking, public health education), and this aspect is prominent in the work. Health education is one of the new functions of the medical officer of health and that is why the volume may well find a place on his bookshelf. The legal and administrative aspects of public health in this country and in America present considerable differences, and the book will be found stimulating to thought for precisely this reason.

The section on tuberculosis is of particular interest. A letter from a High Court judge to the superintendent of a sanatorium, explaining why he had not caused a tuberculous child to be compulsorily committed to the institution, is an unusual item and one indicating that this is not just another textbook of public health.

There is a statement in relation to activated sludge which requires some elucidation. Among the advantages of this method of sewage treatment is mentioned low operating cost, but the next line gives among its disadvantages that of high operating cost; one may well ask how this can be. There are some excellent illustrations of American sewage disposal plant in this section.

Anyone who has produced a book dealing with an advancing subject will know how soon it is out of date, but it was very unkind of fate that in the excellent brief classification of the value of minerals in water there should occur, relative to nutritive trace elements, the statement, "All except cobalt are necessary to human nutrition." And now cobalt has been found to be a constituent of vitamin B_{12}, the anti-pernicious-anaemia factor.

C. O. STALLYBRASS.

FACTORY AND MINE HYGIENE

History of Factory and Mine Hygiene. By Ludwig Teleky, M.D. (Pp. 342. 25s.) Columbia: University Press. London: Geoffrey Cumberlege. 1948.

Written by an acknowledged authority, and with an introduction by Dr. Alice Hamilton, this book raises more hopes than it fulfils. Too much has been attempted, and the main argument is obscured by detail.

The author's thesis is an important one, and has been fully established. It is that "laws and regulations (thoroughly worked out) are indispensable to industrial hygiene." As a rider, the need for the active co-operation of all parties is insisted upon. Dr. Teleky stresses and proves the necessity for a scientifically trained Civil Service inspectorate, free from political influences and capable of determining in specific detail the regulations required for every hazardous process.

The book opens with a historic survey of the development of industrial hygiene, particularly in Britain, Germany, and the U.S.A. British practice started "from an outraged national conscience," and German practice from a special concept of the rights and duties of the State. American practice, with its virtues and anomalies, arose from the interaction of three forces—the demands of the workers, employers' interests, and the uncertain influences exerted by both central and local State authorities.

Written primarily with an eye to the contemporary American situation, the author covers an immense field in less than three hundred pages. The history (in three countries) of industrial legislation, co-operating agencies, medical, scientific, and research services, of injury and hazard prevention, of education, and of some special problems such as dust, compressed air, and skin diseases, is surveyed.

Special attention is devoted to the problems of mines and miners. Dr. Teleky is most successful in this part of his book. The section is followed by a chapter on the effects of industrial hygiene, and a summary concludes the text. There is a full bibliography and an adequate index.

Those who are concerned with the legislative aspects of industrial hygiene and are not already familiar with the history of the subject, or those who are interested in the history of industrial medicine, will value this comprehensive survey. As a book of reference it will prove valuable to medical libraries.

H. E. COLLIER.

ALLERGY

Practice of Allergy. By Warren T. Vaughan, M.D. Second edition. Revised by J. Harvey Black, M.D. (Pp. 1,132; 333 illustrations. $15.00 or £3 15s.) St. Louis: The C. V. Mosby Company. London: Henry Kimpton. 1948.

The investigation of allergy has suffered in the past from the uncritical claims of its enthusiastic adherents. This excessive enthusiasm, together with the difficulty of cure, has caused its study to be regarded too lightly by the medical profession in this country. The plain truth is that the allergic diseases are psychosomatic conditions in which the pattern of the mental and allergic processes are so interrelated that truly objective investigation is extremely difficult. This, however, does not detract from the interest or importance of the subject, which is so ably discussed in the new edition of this work.

Readers of this book cannot fail to be impressed by the vast amount of experimental work and the accumulation of clinical observation which it presents. It contains full information on every aspect of allergic diseases. The first 130 pages are devoted to theoretical considerations of the possible mechanism of allergy; the remainder deal with its more practical aspects. Over two hundred pages are devoted to food allergy. This subject has always received more attention in the United States than in this country, and it is not easy to decide whether it is overdiagnosed there or overlooked here, or if there is a real difference in incidence in the two countries. There can be little doubt, however, that if the patient and detailed investigations recommended by the authors were carried out in suspected cases here many more of that vague group of dyspepsias labelled "functional" would be found to be due to food sensitivity. On the other hand, it is difficult for us to believe that approximately 50% of Americans have some form of allergy to food.

There is a well-documented chapter on so-called physical allergy. This condition also receives scant attention in this country, although there is evidence that physical factors are responsible for the precipitation of attacks of asthma, urticaria, and similar illnesses far more commonly than is generally recognized. Little reliable work has been done to explain the way in which these factors produce their effects, and it may be that use of the term "allergy," by appearing to offer an explanation, has served only to obscure it.

The sections relating to drug allergy and contact allergy are of exceptional interest. Detailed information is also supplied for preparing extracts of all the important allergens (atopens).

An extensive bibliography is provided at the end of the volume. It is unfortunate that not all the papers referred to in the text are included.

This is an excellent book in which one of the leading American exponents of allergy has set down the results of his extensive experience. It contains a critical and up-to-date review of the literature, and this makes it a valuable reference book. It can be whole-heartedly recommended to all interested in the subject.

R. S. BRUCE PEARSON.

BLOOD SUBSTITUTES

Blood Derivatives and Substitutes. By Charles Stanley White, M.D., Sc.D., and Jacob Joseph Weinstein, B.S., M.D. (Pp. 484; illustrated. £2 1s.) London: Baillière, Tindall and Cox.

This book gives a description of current American practice in the preparation and administration of plasma and plasma substitutes. Most aspects of the subject, both practical and theoretical, receive comprehensive treatment, and it can be said that this is a valuable work of reference to what has been and is being done in this field in the United States, written by workers with much experience of what they describe. British methods differ considerably from American ones, and the book cannot therefore be used as a routine guide in this country. The historical section is, on the other hand, refreshingly broad-minded in giving credit to the pioneers of transfusion in all countries.

There is a good account of the physiology and biochemistry of plasma, but it may be questioned whether it is needed in a book of this type. The techniques of preparation, storage, and administration of liquid and dried plasma are treated extensively and well, but with a totally unnecessary wealth of photographic illustrations, many of them simply representing labelled bottles, or even the cutting of a rubber tube with a pair of scissors. There follow chapters on plasma fractions, on by-products of plasma preparation, and a somewhat inadequate section on plasma substitutes in which little is said of the extensive work done in the past on gum saline; nor is there any reference to the important recent Swedish research on dextran. Further sections discuss human serum, blood preservation and transport, and the clinical results of plasma administration.

In a final chapter on reactions the account of homologous serum jaundice is totally inadequate. Less than a page is devoted to what is in practice, both in the United States and England, the most dangerous of all sequels to plasma administration; nor is any useful guidance given for the prevention of this complication. The mere avoidance of donors with a history of jaundice gives little protection. The recommendation regarding donors who may have run the risk of yellow fever infection is not relevant unless they have received vaccine prepared with human plasma.

The book will thus be of greater interest to those concerned with the administration of blood collection, processing, and transfusion than to clinicians.

A. E. MOURANT.

HAEMOSTATIC AGENTS

Hemostatic Agents. By Walter H. Seegers, M.S., Ph.D., and Elwood A. Sharp, M.D., Sc.D. (Pp. 131; 27 figures. $4.75 or £1 5s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1948.

This small book provides a useful review of the haemostatic agents which have been developed as a result of the study of blood coagulation and fractionation of the plasma proteins. Professor Seegers is well known for his work on the physiology of coagulation, and Dr. Sharp has been largely responsible for the development of haemostatic materials by Parke, Davis, and Company.

The first section describes the process of clotting on conventional physiological lines, although greater stress than usual is laid on fibrinolysin. The chapters discussing the practical uses of the haemostatic agents will be of greater interest to clinicians. The value of thrombin solution in the control of haemorrhage in prostatectomy and other surgical operations is reviewed, although no mention is made of its use in the arrest of haemophilic bleeding. Fibrinogen solutions have been employed for the fixation of skin grafts and for nerve suture. They have provided an ingenious method of pyelolithotomy, whereby the ureter is occluded and the renal pelvis filled, through a small incision, with fibrinogen and thrombin solutions. The resulting coagulum is withdrawn through the usual incision, and enmeshed in it are all the stones lying free in the renal pelvis. The final chapters deal with the absorbable materials which may be used as haemostatic agents, alone or in combination with thrombin. Oxidized cellulose and fibrin foam are familiar to most surgeons in this country, but gelatin sponge, which has uses similar to those of fibrin foam, is less well known.

This book is an opportune résumé of the newer methods of obtaining haemostasis. It is, moreover, a tribute to the fertile co-operation of physiologist, clinician, and manufacturing chemist.

R. BODLEY SCOTT.

ADVANCES IN PSYCHIATRY

Modern Trends in Psychological Medicine, 1948. Edited by Noel G. Harris, M.D., F.R.C.P., D.P.M. (Pp. 450; 25 figures. £2 10s., plus 1s. 6d. postage.) London: Butterworth and Co. 1948.

The editor undoubtedly had a difficult task in choosing the subjects to be covered in an account of modern trends in

psychiatry, for these are diverse and chaotic. Nevertheless, much of the interest this work will arouse will come from the fact that psychiatry has so many growing points, for the first time included in a comprehensive book.

Psychiatry is changing under our eyes, and what seems to be a dominant trend to-day may in twenty years be looked on as a blind alley, an eccentricity of our age which led nowhere. Dr. Harris says in his introduction that the most important requirement in psychological medicine is a narrowing of the gap between this and other branches of medicine. Yet an exactly opposite view could equally well be taken. Fissiparous tendencies get stronger rather than weaker with the years. The gap between psycho-analysis and the older psychiatry has widened since the days when Bleuler formulated the concept of schizophrenia, and he and his collaborator Jung used psycho-analytic ideas in the interpretation of psychotic symptoms. Psycho-analysis itself is splitting into warring camps, and the American school, which attributes the cause of psychiatric syndromes almost entirely to "sociogenetic" factors, has moved far from the position taken by Freud and still maintained by his more orthodox followers. The psychodynamic school branches and proliferates, and has now invaded industrial medicine, sociology, anthropology, and at last politics, economics, and statecraft. Reflections of these developments are found, as is proper, in this book.

In all, six chapters are given to psychosomatic medicine, the physiology of emotion, constitution, causation, electrophysiology, and physical treatment. The remaining thirteen chapters are allotted to social and psychodynamic aspects. As in all such collections of contributions from many authors, some chapters are excellent and others less meritorious, some are informative and factual and others speculative and dogmatic. The opinions voiced in some sections are in direct contradiction to those expressed in others. The reader may make his own choice. No doubt the views he adopts will be determined less by rational than by emotional considerations, but, whatever they are, if he looks diligently he will find authoritative support.

ELIOT SLATER.

COMMON SENSE ON CHILDREN

The Child: An Adult's Problem. By Anthony M. Ludovici. (Pp. 288. 10s. 6d.) London: Carroll and Nicholson.

Mr. Ludovici is a cynical and dogmatic writer who will no doubt shock many people; nevertheless there is a great deal of sound common sense in what he says. He deprecates the conventional child-worship based on Wordsworth's conception of the innocent child trailing clouds of glory. This is part of what he regards as a retreat from adulthood, seen especially in women who desire power over children, pet animals, and the poor. Adults pretend they remember the innocence of their own childhood; but the child is prevented only by his muscular weakness and incoordination from behaving in the most asocial or antisocial way. This tendency can be counteracted only by the imposition of proper discipline, which is not synonymous with punishment. Corporal punishment should never be needed if mutual love and respect between parent and child have been established from the earliest years. A spoilt child generally reflects narcissism in the mother, which is likely to be greater the older she is. In this sex-phobic society the child is venerated because he is supposed to be sexless; but to parents, and especially to fathers, he is a manifestation of their sexual potency. He is a means of achieving ascendancy, yet each parent tries to win his love. There is therefore considerable confusion in relation to the child, which may be reflected in the present confusion of the world. The elders are gradually losing the respect of the child and dominance over him, and this is responsible for much delinquency. The proper way to train the child is discussed, and there is a sensible final chapter on sex education. This is a provocative and well-written book which should prove of interest to a large circle of readers, and certainly to the medical profession.

HYPNOSIS IN TREATMENT

The position of hypnotism in medical practice is ambiguous: only a small minority of doctors take an interest in it, or make any practical use of it, and the majority of their colleagues are sceptical of the value of the results obtained. Owing to public displays of hypnotism on the music-hall stage, the atmosphere that gathers about the hypnotist, even the medical hypnotist, does not provide the sort of climate in which most medical practitioners feel at home. The practice of hypnotism is ancient. Priests of all religions have at times employed it to produce apparently occult effects. It was introduced to medicine by Franz Anton Mesmer, a physician who practised in Vienna 150 years ago, and Mesmer himself is said to have learnt the technique from a Catholic priest who used it to exorcise devils. Mesmer applied the method to the cure of patients and, discarding any notion of divine intervention, tried to explain his results by the theory of a "magnetic fluid" which was supposed to flow from the hypnotist into his subject. Disease was due to an abnormality in the flow of the magnetic fluid, and could be cured by correcting its flow. Finding medical scepticism and resistance in Vienna, Mesmer moved to Paris, only to meet the same fate there. His spectacular successes and a technique which was not lacking in some charlatanry caused ill feeling in his colleagues, and a commission adjudged him a fraud.

Mesmer died in obscurity, but his practices found other adherents, and since then a series of honest and respectable medical men and psychologists have developed the technique of hypnotism, simplified theoretical explanations, and added to our knowledge of its physiological nature. Better known among these names are those of Forel and Moll on the Continent, of Braid and Bramwell, and, in recent years, of Brown and McDougall in this country. Surgical operations under hypnotic anaesthesia are first known to have been performed in France in 1821. Isolated instances of the use of hypnotism for this purpose have been reported in the medical and general press ever since. A field in which it is said to be particularly valuable, and which has attracted some recent notice, is the reduction or abolition of the pain of childbirth. One of the greatest difficulties in the practice of hypnotism is the unreliability and unpredictability of its effects: it is likely that the mother in the early stages of labour is in a more than usually suggestible state, and so is an exceptionally good subject for hypnotism.

The principal use of hypnotism has been for the relief and cure of neurotic, especially hysterical, symptoms. Hypnotic and hysterical states are closely allied, and both depend largely on suggestion and on a mechanism, which is not fully understood, of functional dissociation in the central nervous system. Effects can be produced both by hypnotism and in the course of hysterical illnesses which are beyond the capacity of the organism in ordinary circumstances. Estabrooks,[1] for instance, has reported that with the same electrical apparatus and methods of securing contact normal subjects found 15 volts painful and 20 volts unbearable, while 120 volts were taken without flinching under hypnotic anaesthesia. The cataleptic and paretic phenomena which can be induced by hypnotism also seem to be beyond serious question. Rather more doubtful are the claims which have been made that under hypnotism a direct suggestion can alter the rate of the heart or cause local dilatation or constriction of blood vessels, or that the central nervous system can be made more efficient by the production of a so-called hyperaesthesia or hypermnesia. Even with its admitted possibilities it is clear that hypnotism could be of service in the treatment of hysterical anaesthesias, pareses, spastic conditions, and amnesias, and that it might prove of value in the treatment of such single symptoms as headache, insomnia, tics, stammer, or enuresis.

The value of hypnotherapy is increased by the possibility of post-hypnotic suggestion. After waking from the hypnotic trance the subject has no recollection of the suggestion which the hypnotist has given him until it arises in his mind, apparently *de novo*, at the stated time or occasion. This is very frequently used in stage displays, and then often has a most unconvincing quality. At the appropriate signal the subject does indeed carry out the hypnotist's command, but, it appears to the observer, only by his own consent. The stage subject has himself a desire to make a good "show" and is no doubt prepared to co-operate in performing at the right time any action which is not too ridiculous or humiliating. The value of post-hypnotic suggestion for therapy lies almost entirely in its enabling the patient to do something which he badly wants to do but which he is ordinarily prevented from doing, and not in compelling him to do something which he does not wish to do.

There is very great variability from subject to subject in the ease with which a hypnotic state is induced, and also in the same subject from time to time. There are

[1] *Hypnotism*, 1943, New York.

also interesting differences from subject to subject in the neurological and psychological pattern which is induced. Some subjects fall at once, without any suggestion given to this effect, into a cataleptic and anaesthetic state, and others show few, if any, signs of this. Some patients, while hypnotized, seem to have a general clouding of consciousness, whereas in others there is a much greater degree of dissociation between one function which is depressed and others which are maintained in normal alertness and responsiveness. It is, however, probably true that all normal individuals, if fully co-operative, are capable of being put into a hypnotic state, and that with practice the state can be induced more and more easily and made progressively deeper.

To a certain extent, therefore, the main difficulty in the way of a more extensive use of hypnotism both for surgical anaesthesia and for psychotherapy might be overcome by greater medical interest in the subject. There is no evidence that in capable and conscientious hands hypnotism, repeated as many times as is desired, carries with it any physical or psychological danger to the patient. It is, however, most unlikely that more than a small proportion of doctors will be tempted to make any extended use of hypnotism in their practice. The technique of inducing the hypnotic state consists in telling the subject with the greatest conviction and impressiveness something that is not strictly true—for instance, that his limbs are feeling heavy, his lids droop, and he is becoming sleepy. Such things are said, and have to be said, in the hope that their saying will make them come true. Certain temperaments will find actions of this kind either antipathetic or ridiculous, and the technique cannot then be carried through with the inner certainty and self-assurance which are imperative for success.

Despite this and other limitations, however, hypnotism might well be more widely employed than it is at present, both as a harmless local anaesthetic in suitable subjects and in suitable circumstances and for the relief of psychoneurotic symptoms. Effective short cuts in psychotherapy are very urgently required. No one would now claim that psycho-analysis is the treatment of choice for more than a small minority of neurotic patients: the time it requires is a very practical difficulty. Nevertheless there is a large amount of neurotic illness which is not as yet effectively treated but is of its nature capable of treatment. For some of these sufferers hypnotism might offer substantial relief. Above all it seems desirable that hypnotism should be investigated more thoroughly along neurophysiological lines. The systematically applied interest of trained and critical minds might do much to clear up present obscurities, remove unfavourable impressions, and increase understanding of higher cortical activity in the brain.

TREATMENT OF PULMONARY STENOSIS

The surgical treatment of congenital heart disease has proved to be one of the most spectacular of recent therapeutic advances. It is only 10 years since Gross[1] first successfully ligated a patent ductus arteriosus, and the passing of this landmark led to attacks on the problems of coarctation of the aorta and pulmonary stenosis. In the latter condition the object of surgery must be to increase the oxygen saturation of the blood, which fails as a result of the stenosis to be fully exposed to the oxygen in the lungs. The "blue" blood from the right ventricle passes in part through the defect in the interventricular septum into the overriding aorta, thence into the systemic circulation. Experimental work in which the subclavian artery was used to make an artificial channel in coarctation of the aorta pointed the way to the successful treatment of the "blue baby." If some of the systemic blood could be deflected by an artificial "ductus arteriosus" into the pulmonary artery then oxygenation would be improved and some amelioration of the general condition might be expected. Eventually Blalock and Taussig[2] devised a brilliantly successful operation: this was the anastomosis of a systemic vessel, usually the subclavian, with the corresponding pulmonary artery. It has fully justified its conception, for it has provided relief for many patients suffering from a most distressing and hitherto incurable disability.

The technical skill and experience required for this form of surgery are apt to overshadow the careful work of investigation that must be carried out when assessing the suitability of patients for operation. To obtain successful results closely integrated team-work is necessary, and, in addition to the surgeon and anaesthetist, physicians, radiologists, and physiologists all have an important part to play. The recent publications in this country by Campbell,[3] by Baker, Brock, Campbell, and Suzman,[4] and by Rink, Helliwell, and Hutton[5] describe the problems which must be faced by those who undertake the surgical treatment of congenital heart disease, but clearly the results amply justify the risks taken. In the opening pages of this issue Mr. R. C. Brock makes another important contribution to the literature on the subject. In discussing the surgery of pulmonary stenosis he gives instances of the enormously increased capacity for exercise in children who have had operative treatment. Out of the first 50 patients operated on in Guy's Hospital two-thirds were benefited to an extent that was regarded as "almost perfect." This more than offsets a mortality of 14% and a similar proportion of indifferent results.

[8] *Lancet*, 1948, **1**, 988.

Blalock[6] has published a much larger series (610 cases) and reports a slightly higher death rate (17%); in three-quarters of his cases the results were described as excellent. If surgery required any further justification it would be given in Campbell's observations that only one in two "blue babies" will survive to their seventh year and that less than one in 10 will reach the age of 21.[3]

There are many technical problems in this branch of surgery. The standard Blalock operation has now been frequently described, but individual surgeons have modified the procedure in certain respects. Brock now prefers a left postero-lateral approach, for it has the advantage of permitting full exposure of the pericardium, and it allows a choice of a subclavian-pulmonary or pulmonary-aortic (Pott's operation) anastomosis. Stenosis of the pulmonary valves themselves has been recognized, and deliberate division of the valvular obstruction has been successfully carried out by Brock,[7] who reported three cases in this *Journal* last year, and by Holmes Sellors.[8] This has required an intracardiac approach, and Brock has now developed the operation further by punching out or dilating the narrowed channel in selected cases of infundibular stenosis. This method of establishing a more normal circulation may prove to have advantages over the "artificial ductus." The surgery of pulmonary stenosis is now well established, for the immediate results are more satisfactory than anyone with knowledge of the condition could reasonably have hoped for, but time will decide whether the full benefits of either type of operation can be maintained indefinitely as the growth of the patients progresses.

DIPHTHERIA IN SCOTLAND

The advantages of the co-operative form of inquiry are many, among them being the fact that investigations by several teams of workers permit the most to be made of what might individually have formed a relatively useless experience. In recent years the Infectious Diseases Subcommittee of the Scientific Advisory Committee of the Department of Health for Scotland has produced two reports on cerebrospinal fever, and in a third it has accumulated statistics on the behaviour of diphtheria in Scotland during 1942.[1] Such analyses are to be encouraged, for, despite the great changes that have occurred in the severity and mortality of infectious diseases in the last 20 years, readers still have to depend too often upon the descriptions of the disease enshrined in such canons as Ker's earlier editions.

A total of 4,272 cases—about 46% of all those admitted to hospital with diphtheria in Scotland during 1942—came under review, and the first point to be noted is that despite the high prevalence (70%) of gravis infections the mortality was less than 3%; even in the youngest age groups (0–4 years) the mortality was only 6%. The type of organism was certainly important, for in gravis infections the fatality rate was 4%, whereas the rates for intermedius and mitis infections were 0.8% and 1.5% respectively. The low incidence of toxic complications and the infrequency of extensive membrane formation were also indications of the comparative mildness of the disease. Nerve palsies occurred in 4% and circulatory complications in a further 7% of the patients. The former figure is indeed surprisingly small, though it could be argued that in young patients mild degrees of palatal and ocular paralysis might escape attention. Nevertheless, the rate in children under 10 years was twice that in the older patients. The fatality rate in patients who developed circulatory complications was 22%, and in patients with nerve palsies only the rate was 4%. The acquisition of some basic capacity to withstand diphtheria as age advanced was shown by the steady reduction in toxic complications in each succeeding age group; in fact, over 70% of the affected patients were under the age of 10 years.

Membrane was confined to the tonsils in nearly 75% of the cases, and the fatality rate in this group was 1%—a result in accordance with experience, for such cases are not usually severe. When membrane extended to the pharynx the rate increased to 13%. Further analysis of the data collected about the site of infection brought to light two interesting facts. In the first place the gravis types produced the highest proportion of pharyngeal cases—a surprising result, since it conflicts with McLeod's[2] suggestion that membrane formation is greatest in mitis infections. But perhaps of greater interest was the differential increase in mortality produced by the different types when membrane extended beyond the tonsils. In pharyngeal infections with intermedius and mitis organisms the mortality was 26 times greater than in the relatively innocuous tonsillar infections. On the other hand, with the gravis organism the mortality of pharyngeal infections was nine times that of tonsillar infections. Thus the tonsils were much less able to resist toxin when the gravis organism was present. When infections with the gravis type extended beyond the tonsils the fatality rate was 17%.

In the second part of the report the course of the disease in inoculated and uninoculated patients is compared. In 1942 diphtheria immunization had only recently become a matter of national importance, and the number of patients who had been inoculated was only one-quarter of the total, the majority of them being children of or below school age. With the disease taking a comparatively mild form, it might have been expected

[1] *Diphtheria*. Report by the Infectious Diseases Subcommittee of the Scientific Advisory Committee, Department of Health for Scotland, 1948. H.M.S.O.
[2] McLeod, J. W., Orr, J. W., and Woodcock, H. E. de C., *J. Path. Bact.*, 1939, 48, 99.

that the benefit of immunization would not be very obvious; neyertheless, the inoculated patient fared better in every way. Perhaps the most noticeable effect was the reduction of the fatality rate in patients with toxic complications from 27% to 9%. The occurrence of such complications was of course less frequent in the inoculated group, and yet the incidence of gravis infections was actually higher, especially among the younger children.

Public health workers will be glad to have further evidence of the efficacy of diphtheria immunization; but they may think that the great merit of this report is the authentic information given about the character of an infectious disease at a particular time. If the Scottish Committee is searching for fresh work it might well undertake to supply similar information on the behaviour of other infectious diseases.

THE MANAGEMENT OF INTRACTABLE PAIN

While the commoner analgesics generally control pain in acute illnesses, their use in more chronic conditions often presents many obvious disadvantages, chief of which is the development of tolerance and addiction. In the treatment of such disorders as inoperable malignant disease, causalgia, painful amputation stumps, and crippling arthritis it is natural that attempts should have been made to provide relief by surgical interruption of nerve pathways, and operations such as neurectomy, sympathectomy, procaine nerve-block, and chordotomy have all had some success in the past. In a proportion of patients treated surgically, pain is apt to return after a variable interval, either because pain impulses utilize alternative pathways or because the operation itself established new foci of irritation in the central nervous system.[1] Following Rowbotham's[2] treatment of facial pain by intramedullary tractotomy, Crawford[3] has used this operation to control persistent pain in other conditions, chiefly inoperable cancer. In a series of 11 cases there were three deaths, two of which occurred in the only patients subjected to the bilateral operation. The chief limitations of this method are that the operation is a severe one, demanding highly skilled neurosurgery, and it must be bilateral to provide relief in many cases—e.g., visceral growths. For the present, therefore, this operation will probably be confined to those cases of severe intractable pain in which more conservative methods have proved inadequate.

Approaching the problem in another way, Freeman and Watts[4] have found that prefrontal lobotomy helps these patients. They emphasize that pain is essentially a psychosomatic phenomenon—a sensory perception which, signalling a threat to the safety of the organism, produces profound and distressing psychic reactions. While the actual threshold of perception for pain impulses is fairly constant in all normal people,[5] this psychic reaction varies widely with individual make-up. Prefrontal lobotomy leaves pain pathways intact, so that pain perception remains. The normal physical reactions to pain, such as pupillary dilatation, elevation of blood pressure, pallor, and sweating—responses mediated through the sympathetic nervous system—still occur, as may be demonstrated by the muscle-ischaemia test performed on patients who have been subjected to lobotomy.[6] But the operation largely abolishes foresight, concern for the future, preoccupation with self, and the dreadful anxieties which so often accompany severe pain. The patient continues to feel his original pain, but that pain is no longer of greater significance than the appreciation of any other sensory stimulus. The emotional colouring which makes pain so distressing is eliminated, and with it the patient's fear of the future consequences of his disease. The operation had the same effect on incapacitated depressive psychotic patients who complained of pain out of all proportion to the somatic disorders present, examples of what Freeman and Watts call "psychalgia."

Though the technique of the operation is relatively simple, frontal lobotomy causes profound temperamental changes, some of which are socially undesirable. This treatment, therefore, must be recommended with caution, unless the patients are definitely psychotic, such as those in Freeman and Watts's second group.[7] However, the effects of prolonged pain for which no radical relief is possible and the anxieties inseparable from incurable disease are in themselves almost certainly more destructive than the effects of this admittedly imperfect operation. More widespread trial of the method is therefore justified, particularly in patients suffering from inoperable cancer.

Elsewhere in this issue Dr. E. B. Strauss again stresses that all pain is, eventually, a psychic event and an emotional experience. Psychogenic pain—that is, pain which continues in the absence of organic disease—is often an important factor in the persistence of an unstable psychic equilibrium. Its removal by psychotherapy may therefore precipitate the development of a previously latent psychosis in which the guilt factor is prominent. In the same way pain persisting after its original cause has apparently been cured may conceal an already established drug addiction. The diagnosis of psychogenic pain should not be loosely employed, for it is dangerous unless all possibility of organic disease has been carefully eliminated. Prolonged pain from any cause can lead to the development of psychic changes and increased susceptibility to all painful stimuli: resistance is diminished by suffering. In such cases good response to suggestion and innocuous injections may appear to confirm the diagnosis of psychogenic pain, whereas such behaviour really indicates that the pain has a somatic origin. Paradoxically, as Strauss mentions, organic rather than psychogenic pain is the more amenable to psychotherapy, particularly to hypnosis. Salter[8] maintains that hypnotic and post-hypnotic phenomena are conditioned reflexes. If this view is confirmed there is no reason why an individual should not be trained to provide the appropriate stimulus himself. Thus by autohypnosis any sensory perception, including that of pain, could be abolished at will. These are novel concepts, but they are worth considering, for the relief of suffering without the disadvantages of mutilating surgery or disintegration of the personality would be a true conquest of pain.

FAMILIAL HEPATIC CIRRHOSIS

In 1903[1] Parkes Weber described two cases of hepatic cirrhosis in the same family, and since then many examples of familial cirrhosis have been reported.[2-4] In most instances the disease affected siblings born of healthy parents. Débré[5] recognized three clinical variants of the disease, the first being characterized by ascites, the second by biliary cirrhosis and jaundice, and the third by splenomegaly and portal hypertension. The third type, in which the clinical course resembles that of Banti's syndrome, is sometimes referred to as "familial anicteric anascitic cirrhosis." Elsewhere in this issue Dr. A. M. Nussey reports a family in which three of five children suffered from this disease, and he adduces convincing evidence that the cirrhosis in these cases was a manifestation of Rh isoimmunization. The father of the family was heterozygous Rh-positive and the mother Rh-negative. The eldest child, who was Rh-negative, and the second child, who was Rh-positive, were healthy. The remaining three children were Rh-positive, and all three had splenomegaly and repeated haematemeses. None of the patients had been jaundiced in the neonatal period.

It is conceivable that there was a fortuitous genetic link between the inheritance of the Rh factor and the liver defect in these children, but the sparing of the first Rh-positive child is much more in keeping with the natural history of haemolytic disease of the newborn. Many of the families reported before the discovery of the Rh factor showed similar freedom in the firstborn.[2-5] Moreover, it is known that Rh immunization gives rise to liver disease. Henderson[6] described diffuse hepatic cirrhosis in macerated foetuses and regarded this as being the most severe form of haemolytic disease, and later workers have confirmed that liver damage is by no means uncommon.[7-10] It has also been shown that congenital obliteration of the bile ducts[11] and hepato-splenomegaly in childhood[12] may develop after haemolytic disease of the newborn. It seems probable, therefore, that familial anicteric cirrhosis may well prove to be a manifestation of Rh incompatibility. This discovery may help to separate cases of non-familial congestive splenomegaly from the mixture of entities labelled Banti's syndrome.

ANTHRAX AND AUREOMYCIN

The potentialities of the newer antibiotics are now being rapidly explored. We have recently published a report by Drs. J. F. L. Walley and T. V. Cooper[13] of a case of undulant fever treated by chloramphenicol ("chloromycetin") and an account of the treatment of urethritis with "aureomycin" by Drs. R. R. Willcox and G. M. Findlay.[14]

In this issue of the *Journal* Professor J. C. Cruickshank describes work which indicates that aureomycin does not control experimental melioidosis. In Mexico, Ruiz Sanchez and his colleagues[15] have brought forward evidence to show that anthrax can be readily controlled by the oral administration of aureomycin. Tests *in vitro* on six strains of anthrax bacilli show that aureomycin inhibits the growth of the anthrax bacillus in concentrations of 5 μg. per ml. Penicillin *in vitro* is more active, for the inhibitory concentration is 0.02 μg. per ml.; that of streptomycin is 0.5 μg. and of chloromycetin 50 μg. In doses of 10 mg. per kg. of body weight aureomycin protected guinea-pigs from a fatal infection by anthrax. In two human patients suffering from malignant pustule good results were obtained. The doses used were 100 mg. per kg. of body weight by mouth for 3½ to 5 days, followed by 50 mg. per kg. of body weight for a further two days. The administration of aureomycin was followed by a rapid improvement in the clinical condition and a prompt fall in temperature. Anthrax bacilli could not be isolated from the lesions three and four days after the beginning of aureomycin treatment.

LUPUS ERYTHEMATOSUS

Acute lupus erythematosus was first described by Kaposi[1] in 1872, and for twenty or thirty years thereafter it was regarded as a primary dermatological condition, the accompanying general symptoms being put down to the toxic effects of severe skin involvement. Morbid anatomical definition of the disease was difficult, since necropsy findings were very variable, but Libman and Sacks[2] made the valuable discovery of an unusual form of endocarditis characterized by flat pinkish vegetations occurring at the base of the valves, usually beneath the posterior cusp of the mitral valve. Small necrotic foci are found in the myocardium, but it is difficult to assess the severity of the cardiac condition during life because of the many symptoms. In a recent review Humphreys[3] has suggested that electrocardiographic studies are useful, though the results may be confusing if a pericardial effusion is present. In 1935 Baehr, Klemperer, and Schifrin[4] demonstrated widespread lesions of blood vessels and serous surfaces, particularly degenerating and necrotic lesions associated with thrombosis and haemorrhage. They noted a glomerular change in the kidney, with a peculiar hyaline thickening of the basement membrane known as the "wire loop" lesion. In all areas of the body there are changes in the collagenous portions of fibrous tissue, but the exact nature of these is undetermined. Klemperer[5] believes that they are an important feature of the disease.

Widespread connective tissue changes occur in generalized scleroderma, rheumatic fever, and periarteritis nodosa, as well as in lupus erythematosus. This suggests the possibility of a common cause, but the evidence in favour of

such a theory is slender. Bacteriological examination of many tissues before and after death has not revealed any organism as the immediate cause of the disease, and the suggestion that it was tuberculous in origin—seriously considered over many years—was finally disproved by Keil[6] in 1933. Some authors have considered hypersensitivity to bacteria or bacterial products as a probable cause. The fibrinoid collagen changes so frequently found in lupus erythematosus are held to be evidence for this theory, but such changes have long been known to occur in bacterial infections, in inflammations due to chemical and physical irritation, in compensated hypertension, and even as a result of simple trauma such as squeezing the skin.[7] Fibrinoid collagen alteration cannot therefore be regarded solely as an expression of hypersensitivity.

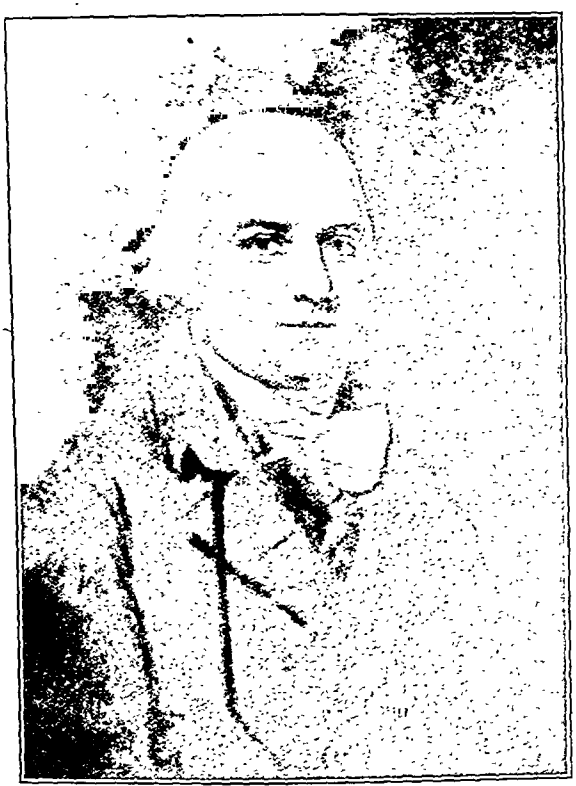
Another microscopic change which is a feature of both lupus erythematosus and generalized sclerodermia is an alteration in the homogeneous ground substance, which is composed of a variety of mucoproteins. This change may prove to be a guide to the cause of the disease. It is known that the colloidal state of the ground substance is affected by hyaluronidase and that various female sex hormones seem to exert an opposite effect. Wolbach and Howe[8] have studied the action of ascorbic acid on the ground substance and its relation to collagen fibrin formation. But such evidence as there is about the cause of lupus erythematosus is fragmentary and obscure; there is ample scope for further investigation.

RESECTION IN PULMONARY TUBERCULOSIS

During the past few years pulmonary resections have been successfully carried out in an increasing number of cases of tuberculosis, and it is now agreed that such operations have a restricted but important place in the treatment of this disease. The concept of excision is not new; Macewen[1] removed a tuberculous lung in 1895, the patient being alive and well forty years later, but only sporadic cases were reported until those of Jones and Dolley[2] in 1939. Since then several papers on the subject have been published, chiefly in the American literature, a recent example being a review of 39 cases by Clagett and Seybold.[3] These authors carried out 14 lobectomies and 15 pneumonectomies; four patients have died and five have active tuberculosis, but 19 are apparently well. In most of these cases the follow-up period has been short, but it has been as long as four years in some. No other effective treatment was available for the majority of the patients. More recently Holmes Sellors and Hickey[4] in this country have described their results in a series of 78 patients, of whom 11 died. They performed pneumonectomy in 33 cases and lobectomy in 45. Follow-up histories are not available, but there is no evidence of further tuberculous infection in the surviving patients.

There are two groups of cases in which resection is indicated. The first are those in which collapse therapy has failed. Examples in the series of Clagett and Seybold include a patient with a thick-walled cavity in the upper lobe persisting in spite of a satisfactory artificial pneumothorax, and a patient with a dorsal cavity in the lower lobe not responding to pneumoperitoneum and phrenic crush: for both of these a lobectomy was found adequate. In another patient the sputum remained persistently positive in spite of an adequate revised thoracoplasty; there was no tracheobronchial ulceration, disease in the opposite lung, or recognizable cavitation, and a pneumonectomy was performed.

The second group consists of those cases in which experience has shown that collapse therapy is unlikely to succeed. The dangers of pneumothorax with its attendant atelectasis in cases with bronchial stenosis are well known, and this relatively unusual manifestation is perhaps the most widely accepted indication for resection; it was present in 13 patients in this series. Cases of tuberculoma, of tuberculous bronchiectasis, and of associated carcinoma are included in the series, but in such conditions the diagnosis of tuberculosis can usually be made only on the results of histological or bacteriological examination of the excised specimen, and the operation is performed either as an exploration or without knowledge of the accompanying tuberculous infection. In cases with giant cavities, large tension cavities, much destruction of lung tissue, or repeated severe haemoptyses, excision is a desperate resort often giving gratifying results. None of the cases in this series were in children, but before growth is complete resection may occasionally be the operation of choice, since thoracoplasty leads to such severe deformity. The indications accepted by Holmes Sellors and Hickey are very similar.



Complications are frequent. As after any pulmonary resection, a broncho-pleural fistula is serious. Ulceration of the bronchial stump commonly occurs, with a positive sputum as a result, but it usually responds to treatment with local silver nitrate or systemic streptomycin. More important, and indeed the greatest drawback to this method of treatment, is spread of disease to remaining lung tissue or reactivation of quiescent tuberculosis. This may occur either early, immediately after operation, or several months later. In recent cases streptomycin has been used as a prophylactic and has given encouraging results, but it seems unlikely that it will greatly diminish the incidence of late spread, especially as resistant strains of bacilli develop after prolonged treatment. In this connexion the figures of Bailey[5] are remarkable: only one patient out of 100 given streptomycin developed contralateral spread. It seems likely that one of the most valuable uses for streptomycin will be as a cover for surgical treatment: its property of reducing the complications of resection should be particularly welcome.

The Queen has graciously consented to accept the Honorary Fellowship of the Royal College of Obstetricians and Gynaecologists, of which she is the Patron, and has intimated that she will attend the College in the autumn to be formally admitted. Her Majesty has sent a donation of £1,000 to the appeal which is being made by the College for funds urgently needed to meet the financial demands of its ever-widening activities.

ROBERT WILLAN, DERMATOLOGIST

The London County Council has affixed to No. 10, Bloomsbury Square, now part of a hotel, a tablet commemorating the residence there of Dr. Robert Willan (1752–1812), physician and dermatologist. Dr. Willan, who was a native of Yorkshire, was educated at Sedbergh Grammar School and received his medical training in Edinburgh. After some practice in Darlington, during which he wrote a treatise on the sulphurous waters of Croft and Harrogate, he came to London and was appointed physician to the public dispensary in Carey Street, Lincoln's Inn, on its establishment in 1783. He held this appointment

The portrait of Dr. Robert Willan is reproduced from *British Masters of Medicine*, edited by the late Sir D'Arcy Power, by kind permission of the publishers, *The Medical Press*.

for twenty years, after which he was made consulting physician and life governor.

Willan was the first physician in this country to classify the diseases of the skin in a clear and intelligible manner and to place their nomenclature on a satisfactory basis. His classification gained him the Fothergillian medal of the Medical Society of London in 1790. In 1791 he began a series of monthly reports on the weather and prevailing diseases of the metropolis, continuing this for several years. His great work, however—and one of lasting value—was his *Description and Treatment of Cutaneous Diseases*, the first part of which was published in 1798, and the last, posthumously, in 1814.

Willan lived in Bloomsbury Square, then the abode of nobility and fashion, until 1810, when symptoms of pulmonary tuberculosis and dropsy developed and he went to Madeira, where he died in March, 1812. In the *Gentleman's Magazine* for that year he is described as "one of the best and noblest of human kind, possessed of every virtue that can ennoble or adorn. . . . In his profession he was beloved almost beyond example. . . . He possessed almost every intellectual attainment that can be comprised within the finite compass of the human mind."

INTERNATIONAL VETERINARY CONGRESS

ANIMAL DISEASES COMMUNICABLE TO MAN

An International Veterinary Congress was held in London during the second week in August under the presidency of Sir DANIEL CABOT, formerly Chief Veterinary Officer of the Ministry of Agriculture. Delegates from 53 countries attended, and the discussions covered the whole field of animal health, including the control of bovine tuberculosis, foot-and-mouth disease, vaccination, virus diseases of cattle and horses, nutritional factors, veterinary surgery, and animal husbandry in relation to public health. The addresses included one by Lord BOYD-ORR on the world food situation. He declared that modern agricultural and engineering science could double world food production in less than twenty-five years, provided governments would co-operate in a world plan. Loss in human food due to preventable animal diseases probably ran to millions of tons a year. The veterinary profession, which had here a great opportunity, needed a strong international organization on the lines of the World Health Organization through which governments could co-operate in the elimination of preventable diseases on a world scale.

Diseases of Household Animals

One of the sessions, which was shared with the National Veterinary Medical Association, discussed diseases of household animals communicable to man. Dr. J. WINSSER, of Leiden, said that tuberculosis of dogs and cats was rather frequent in the Netherlands, and every animal suffering from this disease was a potential danger to human health. Large dogs were more susceptible, not on account of breed but because of the likelihood of under-nutrition. Among cats Siamese were most susceptible. Infections with the human type of tubercle bacillus predominated in dogs, whereas in cats infections of this type were rare. Both dogs and cats might spread enormous numbers of bacilli by coughing, by their faeces and urine, and by the secretion products of skin ulcers. Therefore it was important that members of the veterinary profession should diagnose the disease as early as possible and get the owner's consent to the destruction of the animal.

Leptospirosis was an important disease in man and dogs in the Netherlands. He mentioned in particular *L. canicola* infections. During the last fifteen years 49 human cases of this infection had been recognized at the Institute for Tropical Hygiene, Amsterdam, and of these six (including one fatal case) showed jaundice. Salmonella infections occurred frequently in dogs, less so in cats. The infected dog during disease and convalescence was a transient carrier, spreading salmonella organisms by means of faeces and urine, and every strain of salmonella was a potential danger to human health. In Sweden two workers had isolated salmonella organisms from the faeces of seven members of a family suffering from gastro-enteritis and from the blood of the family dog. Streptococcosis was a not uncommon infection in dogs and cats both in England and in Holland. There was strong evidence that milk-borne "sore throat" epidemics in man were caused by the *streptococci* residing in the cow's udder.

Among parasitic skin diseases he mentioned microsporum infections (*M. canis*), more common in cats than in dogs, and communicable to man. Dr. Winsser had observed a stubborn infection among Persian cats, from which some adult persons had contracted the disease. Tricophytia was not a rare disease in dogs.

A condition frequently met with food animals as well as in dogs was echinococcosis. The disease was contracted not only by direct contact between animal and man but by contamination of market produce with dogs' faeces. The worm eggs were resistant and might remain fertile for at least a year. Meat inspection regulations had diminished the prevalence of the disease, and there was a continuous decrease in the number of cases in the Netherlands.

In some discussion on this paper Mr. H. W. SMITH, formerly of the London School of Hygiene and Tropical Medicine, mentioned that in 500 specimens of canine faeces salmonella

organisms were isolated from 1%, and from 1.4% of a similar number of samples of feline faeces. Household animals should always be considered as possible sources of outbreaks of salmonella infection, and the practice of leaving cats in shops where there was uncovered food was strongly to be deprecated. Mr. L. K. WHITTEN, of New Zealand, mentioned the serious problem of hydatid disease in that country, both in man and in animals. In a population of 1¾ millions about 100 human cases were seen every year. Some 12% of these were fatal. A campaign had been started to spread knowledge of the cause and control of the disease.

Dr. MARGRIT SCHEITHLIN (Zurich) referred to the prevalence in Switzerland of microsporum infections derived from small animals. Dr. JOAN JOSHUA said that, while transmissibility of disease from animals to man was certainly established, the danger should not be exaggerated. Tuberculosis in small animals in this country was decreasing with the increase in the pasteurization of milk. Leptospirosis had a public health significance, as had salmonellosis, but it was a common experience of practitioners dealing with small animals to be told that children had contracted "worms" from a cat or dog and that the animal must be destroyed, whereas it was often entirely free from parasites. Ringworm contracted from a cat, particularly a blue Persian, was always a possibility. Dr. OLGA UVAROV said that during the last fifteen years she had encountered six cases of sarcophytic mange in women and one in a child as a result of handling dogs, and had also come across one case of ringworm transmitted by an animal.

Tapeworm Infestation

Dr. JOH PETERS (Rotterdam) said that during the invasion of his country the German soldiers often brought with them dogs from the eastern parts of Europe, and these animals frequently harboured tapeworms which contaminated Dutch livestock. The clandestine slaughter on the black market fostered the spread of the parasites. This had now been cleared up, but in man the results of this heavy infestation from dogs could not yet be assessed.

Dr. R. F. MONTGOMERIE, closing the discussion, said that he wondered whether the title of it might not be turned round so they could consider diseases of man communicable to animals. The glass shields at the Zoological Gardens were not designed to protect visitors from animal infection, but to protect the animals from the visitors.

The same subject of transmissibility figured in other papers at the Congress. A Californian delegate, Mr. W. R. HINSHAW, spoke of ways in which the veterinary surgeon could assist in reducing human as well as animal loss from salmonellosis. Those engaged in small animal practice should devote some time to studying this group of diseases as possible sources of illness in cats and dogs, both to reduce loss from salmonellosis in the animals and to prevent human cases by transmission from carriers. Dr. J. N. RITCHIE, of Edinburgh, discussed tuberculosis in cattle from the public-health aspect. In 1948 the number of cattle in tubercle-free herds in Great Britain was 1,704,000 and the amount of milk sold from such herds was 354 million gallons, as compared with 141.6 million gallons five years ago. In another paper Mr. F. BLAKEMAN discussed the relation between human and porcine influenza. He said that the possibility of an exchange of viruses between pigs and the human population must be seriously considered. "Hog flu" was first recognized as an entity at the time of the 1918 pandemic of human influenza. Neutralizing antibodies to the pig virus were later demonstrated in human beings, and the possibility of a relationship between the two conditions must not be lightly dismissed.

Political questions were not in order at the Congress or the N.V.M.A. meeting which followed it, but one session of the latter was devoted to the organization of veterinary practice. Emphatic and uncontested views were expressed against the nationalization of the profession. One speaker declared that that would be the direst calamity that could befall them. He was certain that there were other ways of developing a service which would retain professional freedom and yet enable the practitioners to fulfil their obligations to the utmost.

MORTALITY TRENDS IN THE WAR YEARS

REGISTRAR-GENERAL'S STATISTICAL REVIEW

Two volumes from the Registrar-General's office complete the medical statistical review of the war years. One of them is the medical text for the six years 1940–5 and the other the medical tables for 1944[1] (the tables for 1945–7 have already been published). The period covered by the first volume corresponds, except for a few months at each end, with the period of the war. The time was an abnormal one from a statistical viewpoint, owing to evacuation and other movements of population, to the continued call-up of males, and later of females, and, at the close, to demobilization.

All of the deaths, except some 57,000, were of civilians. Enemy attack accounted for 23,268 deaths in 1940 and nearly as many in 1941, but after that the number was comparatively small, except for 9,000 deaths in 1944 due to long-range projectiles.

One result of the war was the alteration of the sex ratio in the mortality rate. The ratio of male to female mortality has been rising for a hundred years. A century ago it was 109; it rose steadily to 134 in 1939, but the increase was greatly accelerated during the war years. The continued call-up of young fit males and the subsequent discharge of the unfit meant a lowering of the physical standard of certain groups of the male civilian community. This was reflected in a higher mortality as compared with other groups and with females. Thus, if the female mortality be taken as 100, the male mortality for ages 20–25 approached 200.

The standardized (as opposed to the crude) death rate fell from 9.8 per 1,000 living in 1938 to 9.0 in 1945 in the case of males, and from 7.4 to 6.4 in the case of females. The number of people who were over 65 when the war began was 897 per 10,000 at all ages, and when the war ended the number had risen to 1,146. During the war 111 male and 528 female centenarians died. Three of the females were reputedly 108, and a male (who died in Greater London in 1941) was 112.

The war had little effect on diseases of the heart. Deaths from acute and subacute bacterial endocarditis averaged 1,016 annually during the five years before the war and 868 during the war years. The deaths due to rheumatic fever in the four years immediately before the war showed an annual average of 1,000; during the war this figure fell to 638.

Among other wartime effects is to be noted the sharp decline in deaths from alcoholism. Deaths attributed to alcoholism, or to disease said to be due to alcoholism, were 144 in 1940. In the last year of the war they numbered only 26, and deaths to which alcoholism was a contributory cause fell during the same period from 286 to 105. Suicides also declined—a familiar tendency in wartime.

Maternity and Child Welfare

The reduction in the number of deaths from causes connected with pregnancy and child-bearing continued uninterruptedly throughout the war. A remark is made on age as affecting maternal risk. At ages under 25 the risk of death from a complication of childbirth or the puerperium is one in a thousand; by 35 it has reached two in a thousand, and by 40 three. The pronounced improvement in infant mortality which occurred in 1942 was confined to two distinct age periods, the first week and the second half of the first year. Measles, scarlet fever, and whooping-cough had low death rates during the war years. The number of deaths from diphtheria, which in 1935–9 averaged nearly 3,000 annually, fell progressively during the six years of war from 2,480 to 722. It is mentioned that to the immunized child aged 1–5 the risk of dying from diphtheria is less than one-thirtieth of the risk to the non-immunized, and at ages 5–15 the risk is one twenty-fourth.

Acute poliomyelitis and polio-encephalitis notifications continued evenly during the war years. There was no epidemic year such as immediately preceded and immediately followed the war.

[1] *The Registrar-General's Statistical Review of England and Wales for the Six Years 1940–5.* Text, Vol. I, Medical. 6s. 6d. net. *The Registrar-General's Statistical Review of England and Wales for the Year 1944.* Tables. Part I. Medical. 5s. 6d. net. London: H.M. Stationery Office. 1949.

It is pointed out that from 1926 to 1943 there was a progressive change in the age distribution of deaths from this disease. An increasing proportion occurred amongst adults and a diminishing proportion amongst young children. This change was intensified in 1944–5, when only 17% of the deaths were of children under 10, compared with 57% in 1926–30, and the proportion at ages over 25 rose to nearly one-half.

In connexion with the deaths of children, it is startling to note the large proportion due to violence, most obviously road accidents (deaths from war operations are excluded from these figures). For children between 5 and 10 during the war years the rate of deaths from road accidents was something like 250 per million living in the case of boys and 120 in the case of girls. In the medical tables the number of deaths of children up to 15 caused by motor vehicles in 1944 is given as 1,133, slightly less than the number of deaths from scarlet fever, whooping-cough, and diphtheria combined. Nearly one-third of the pedestrians killed on the roads were children under 10. In 1945 violence accounted for more deaths of boys of 10–15 than any other cause. Among girls of the same age, violence, which was fourth in frequency as a cause of death before the war, took second place and was exceeded by tuberculosis.

Death Certification

Much is said in the review about defects in certification of causes of death. In one year something like 14,000 inquiries had to be sent out to medical practitioners to clarify the cause of death for the purpose of statistical classification. Improvement of quality, says the compiler of the review, is to be sought first in accuracy of diagnosis by improving the diagnostic services during life and by performing necropsy more frequently in doubtful cases after death. An important cause of error is the omission from the certificate of the real cause of death because its appearance might be unpleasant or inconvenient to relatives. This problem will have to be tackled boldly if real statistics of syphilis and diseases of syphilitic origin are to be secured. Deaths from syphilis have declined progressively from 1938, when they numbered 3,463, to 1945, by which year they had fallen to 2,395. Deaths under or associated with anaesthesia during the six years numbered 4,775, but it is impossible from the certificate to distinguish between deaths due to the operation and deaths caused by the anaesthetic itself.

Defects in certification of causes of death by coroners are also mentioned, especially failure to state whether a fatal accident occurred in a house, a public building, or out of doors, so that the compilation of the number of accidents in the home has to be based on assumptions and conjectures.

BRITISH PHARMACOPOEIA COMMISSION

APPROVED NAMES

In order to avoid the difficulties which arise from the multiplication of names for the same medicinal substance, the General Medical Council has adopted the practice of recognizing as approved names certain non-proprietary names which may be used freely by manufacturers. The approved names are devised or selected in the first instance by the British Pharmacopoeia Commission, and should any of the drugs to which these are applied be eventually described in the *British Pharmacopoeia* the approved name would be its official title. On the other hand, the recognition of an approved name does not imply that the substance will necessarily be included in the *British Pharmacopoeia*.

The Pharmacopoeia Commission is prepared to consider requests from manufacturers and others for approved names for products which appear likely to come into established use. Such requests should be accompanied by reports of pharmacological and clinical investigations on the drug concerned and suggestions for a suitable name, having regard to the need to avoid similarity with existing trade marks and other current names. In the selection of an approved name the Nomenclature Committee of the Commission will be prepared to consult with authorized representatives of the manufacturer concerned, but the final decision will rest with the Pharmacopoeia Commission. If a manufacturer should desire to issue under a proprietary name a drug for which an approved name has been provided, it is strongly recommended that the label shall bear the approved name in letters as conspicuous as those in which the proprietary name is printed or written.

The following general principles are stated for guidance in devising new names: (1) Names should preferably be free from any anatomical, physiological, pathological, or therapeutic suggestion. (2) An attempt should first be made to form a name by a combination of syllables from the scientific chemical name, in such a way as to indicate the significant groupings of the compound. (3) Names should not exceed four syllables. (4) Names should be distinctive in sound and spelling, and should not be liable to confusion with names already in use. (5) Names which are difficult to pronounce or to remember should be avoided. (6) The addition of a terminal capital letter or number should be avoided. (7) Names used in the *United States Pharmacopoeia*, the *British Pharmaceutical Codex*, or in *New and Non-Official Remedies* should receive preferential consideration. (8) The following terminations should be used: -ine (Latin -ina) for alkaloids and organic bases; -in (Latin -inum) for glycosides, glycerides, and neutral principles; -ol for alcohols and phenols (-OH group); -al for aldehydes; -one for ketones and other substances containing the CO group; -barbitone or -itone for drugs of the barbiturate group; -caine or -aine for local analgesics.

Communications relating to approved names should be addressed to the Secretary, British Pharmacopoeia Commission, 44, Hallam Street, London, W.1.

Reports of Societies

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

MENTAL HOSPITAL ORGANIZATION

Delivering the Presidential Address to the Royal Medico-Psychological Association at York on July 20, Dr. J. IVISON RUSSELL said that whereas the extramural psychiatric services were at one time sadly neglected, and they quite rightly used every endeavour to increase out-patient clinics, psychiatric units, and early-treatment and neurosis centres, there was a possibility that the pendulum might swing too far and that these facilities might be regarded by regional boards as all-sufficient in a scheme of preventive psychiatry.

The task of fitting psychiatry into a regional hospital service would not be quite satisfactory until a pattern of key hospitals and their relationship with associated extramural centres were clearly defined. Was it possible to create in every management area a base hospital that would embrace all aspects and serve as the main centre of a group of treatment units for all types of psychiatric disorder? Could the mental hospital be that base? And, if so, would its present form require to be modified? He believed that could be done if the workers in this field strove individually and collectively to that goal.

How should they plan the mental hospital of the future? If they followed the pattern of general medicine they would have relatively small hospitals to provide curative treatment, and larger infirmaries for the care of long-stay cases. By a process of screening at out-patient clinics and diagnostic units patients would be selected for admission to the hospital appropriate to the nature of the case. But in such a scheme there must always be a last resort to deal with the failures, and some were a little concerned lest this final resting-place might be called the mental hospital.

The modern trend was to evaluate both the physician and the hospital in terms of production and according to the industrial potential of the patient. With that yard-stick psychiatry might sometimes seem to give short measure. It was all the more important that they should guard against an uneven distribution of experienced clinicians which might divert them from the long-stay in-patients.

Aged Patients

At present they had all got in mind the need for special hospital accommodation for aged patients. Some of these old people should not have to be sent to mental hospitals. A more simple type of hospital with good nursing would be adequate and ought to be made available.

While they could not accept the view that the senile patient did not suffer from any psychiatric malady, they would agree that the mental hospital might well hand over its habitual practice of providing large senile infirmaries. Their association would keenly co-operate in any effort to provide alternative care and comfort for the aged.

Group of Units

The mental hospital proper should not be an isolated institution but an extensive group of widely dispersed units, of which the nuclear centre or headquarters hospital would deal with the reception, treatment, and, if necessary, the prolonged treatment of all types of acute and difficult cases, regardless of duration. It would supply the medical and nursing staff for all the subsidiary units and out-patient clinics. Suitable cases would be treated by the same specialists in the psychiatric departments of the general hospitals and at neurosis centres, but these would not be used as screening centres for the main hospital.

Remote from the headquarters hospital, and situated in rural surroundings, relatively small resettlement homes would accommodate those who no longer required active treatment. Some of them would gradually become dispersed in the surrounding villages when the community learned the value of their labour and knew that the hospital would be ready to deal immediately with any difficulty that might arise. On this pattern, and with adequate geriatric units and mental deficiency colonies providing independently for their respective cases, the problem of overcrowding in mental hospitals would be solved, and here and there some ancient blocks could be demolished.

"Royal College of Psychiatry"

Proposing the toast of "The Royal Medico-Psychological Association" at the annual dinner held on the same day, the Sheriff of York, Councillor A. S. Rymer, hoped that the association would endeavour to awaken public interest in the progress that had been made in recent years in the treatment of mental illness and make it known that it was no different from physical illness. In reply, the president said the association looked back with satisfaction on its work of training nurses. The first certificate was awarded in 1890, and since that time more than 54,000 had been issued. In some years there had been as many as 4,000 entries for the examination. This activity would soon be terminated, and it would then be possible to concentrate on the postgraduate training of medical officers. He hoped that the new D.P.M. might some day have a Royal College of Psychiatry behind it, and perhaps, in a future not far distant, students would be taking systematic courses of study at a University of York.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS

The Society of British Neurological Surgeons held its 40th meeting in London on July 22 and 23 under the presidency of Professor Lambert Rogers. The delegates included representatives of the United States, South Africa, Australia, and several European countries. Dr. Ernest Sachs, of St. Louis, was made an honorary member of the Society.

Discussions were held at the National Hospital, Queen Square, and at University College Hospital Medical School, and included a consideration of the neurophysiological studies of the Research Unit under Dr. Carmichael at the National Hospital. Dr. PAUL BUCY, of Chicago, spoke on the surgical treatment of involuntary movement. He said that Parkinson's disease was incurable by operation and the most that could be hoped for was the abolition or diminution of tremor. His own experience and that of almost all United States neurosurgeons had shown that involuntary movements could not be stopped without excising the motor area, which naturally produced profound weakness or paralysis of the affected limb. Dr. KRYNAUW, of Johannesburg, gave an interesting account of his experiences of removing the damaged hemisphere in hemiplegic epileptic children.

At the Society's dinner Dr. ERNEST SACHS gave his reminiscences of Sir Victor Horsley, under whom he had studied neurosurgery, and Dr. FRANCES GRANT, of Philadelphia, spoke about the organization and present trends of neurosurgery in the United States.

Preparations and Appliances

METHOD OF GIVING "V.A.M."

Dr. C. G. BLAKELEY, specialist anaesthetist, Royal Halifax Infirmary and Halifax General Hospital, writes: For nearly three years I have employed "V.A.M." (1 vol. divinyl ether and 3 vols. ethyl ether) in the Coxeter–Mushin apparatus by the convenient method illustrated in the accompanying photograph. The apparatus consists of an ether container from the

Walton Mk. 2, from which the large glass bottle has been removed and replaced by a Boyle apparatus chloroform bottle, thus allowing freedom of movement for the handle of the concertina bag when plugged into the respiratory side of the apparatus. The gas passages are of adequate bore, and clinical experience as well as experiment upon myself give no evidence of embarrassment to the respiration. The virtues of V.A.M. may find a wider application if this simple method is more generally known.

To stimulate public interest in nursing as a profession a mobile nursing exhibition is touring Northern Ireland from Aug. 15 to Sept. 10. The exhibition was opened in Belfast on Aug. 15 by the Parliamentary Secretary to the Ministry of Health and Local Government. It includes photographs illustrating all branches of nursing and midwifery, a small model operating theatre, a display of nursing decorations, nurses' badges, medals, etc., models of nurses' uniforms, and a panorama of nursing through the ages.

Correspondence

Broncho-pulmonary Segments

SIR,—Credit has been rightly given to Drs. J. Hardie-Neil and W. Gilmour, of Auckland, in your annotation (Aug. 6, p. 326) for their valuable contributions to lung anatomy. But it is a matter for some surprise that excellence in one aspect of their work should be marred by the simple *naïveté* of their approach when they embark on comparative anatomy.

In their article (Aug. 6, p. 309) they refer to the results of some dissections published by them in 1946. In themselves the data have some value, but they are wholly inadequate to sustain the conclusions they deem so "obvious" in respect of the homologies of the various bronchi. They examined lungs of only 11 species of mammals, and these belong to five different orders and three different subclasses or infraclasses. No argument is offered as to whether they may be considered generalized representatives of their orders, save their reference to the platypus as "one of the earliest mammals" with an "upper lobe closely resembling that of the human." One of the animals is merely identified as "a monkey," regardless of the fifty-odd modern genera and more numerous species of "monkey" with their very diverse grades of organization.

Now a proper utilization of the comparative anatomical approach demands some attempt to determine the course of phylogenetic modification in the various orders and smaller groups. When some account can be given of the probable course of evolution of lung structure within the orders of primates and artiodactyla respectively we shall be in a better position to judge whether the authors are correct in finding "obvious homologues of the apicals" (of man) in certain minor bronchi of the black buck, or in identifying as an "anterior" bronchus and as "apicals" (using the terms in the human sense) certain bronchi in the dog (in many respects a highly specialized member of the order carnivora). So far as the primates are concerned the authors could have widened the basis for their argument by integrating their findings with those of Narath,[1] who has provided beautiful figures of the bronchial tree and pulmonary vessels in a considerable number of animals. Their claim that "branches"—i.e., bronchi—may fuse is in effect a claim that recognizable primordia in the embryo do indeed coalesce. This is a phenomenon which yet remains to be demonstrated; and it appears to be improbable unless in very early phases of development, since cartilage blocks are laid down at the keels where bronchi join before the human embryo is 2 in. (5 cm.) long.

Human embryo, 20 mm. C.R., transverse section. This shows lateral and medial bronchi of (right) middle lobe, which is separated by the oblique fissure from the apical segment of the lower lobe; and the lingular bronchi of the left lung. Mesenchyme demarcates broncho-pulmonary segments. Reproduced by kind permission of Professor W. J. Hamilton.

A misleading statement regarding development requires comment. The authors state that "a broncho-pulmonary segment . . . is surrounded by connective tissue derived from the visceral pleura." Now "visceral pleura" is generally understood to refer to the covering of the lung which is derived from the coelomic mesothelium of the embryo together with a thin layer of adjacent loose connective tissue which is derived from the splanchnopleur. A lung bud consists in its earliest stage of three layers of tissue: (1) pulmonary epithelium; (2) splanchnopleuric mesenchyme; and (3) coelomic mesothelium. Of these the mesenchyme has long been recognized as the source of the "connective tissue" of the lung, and there is no evidence of its derivation from the visceral pleura.

The general course of subsequent changes is also well known. Substantial quantities of mesenchyme persist for a considerable time between the major bronchi and their derivatives; thus the broncho-pulmonary segments are demarcated from one another even more clearly than in the adult. At this time the mesothelium of the visceral pleura forms a well-defined layer, and it intervenes between segments only where fissures are developing. These fissures very early assume patterns similar to those found in adult lungs, and there is no evidence that secondary closure of fissures takes place on a large scale (though postnatal adhesion of the cardiac lobe is a possible exception).—I am, etc.,

Institute of Animal Physiology, Agricultural Research Council. ARTHUR B. APPLETON.

Treatment of Rodent Ulcer

SIR,—As one who in common with many other dermatologists in Australia sees and treats in any one year more than double the number of basal-cell carcinomata quoted by Sir Cecil Wakeley and Mr. Peter Childs (April 30, p. 737) as having been seen in 35 years, I would like to make the following comments on their paper.

1. No conclusions of proved value can be made from the treatment of such a small number of cases (237).

2. The writers classify basal-cell carcinomata into three main types, whereas here in Sydney we recognize nine different clinical types. But possibly, from the small numbers quoted, they have not encountered some of these types.

3. The choice of therapy in general does not lie between irradiation and excision. With the exception of lesions on the back of the hand or dorsum of the foot the choice of treatment for the great majority of small lesions (where the treated area does not have a diameter greater than 5 cm.) is a combination of the cautery, curette, and *x* radiation (with a half-value layer of from 1 to 2 mm. of aluminium); this gives by far the best cosmetic results. This is obvious when it is considered that only the actual lesion is destroyed and removed with the cautery and curette and not the wider area necessary if the cautery alone or even surgery were used. Also, only 1,800 r of *x* rays are delivered to the base and 1 cm. wide of the visible or palpable margin instead of from 2,500 r upwards if *x* rays alone were used.

4. From the cosmetic point of view the results obtainable by surgery do not even begin to compare with those obtainable by irradiation in the treatment of lesions on the eyelids, nose, or ears. I have yet to see the plastic surgery which can, on the average, re-create a completely normal-looking ear, nose, or eyelid after surgical excision of a relatively large area. When a basal-cell carcinoma involves the cartilage of the ear or nose a very much more normal-looking organ with regard to shape and contour can be left after treatment with radiation.

5. The "attendant disadvantages" are considerably less with irradiation than with surgery in the treatment of large areas (as also with small areas), particularly in regard to cosmetic effect, economy (loss of time and money by the patient through being hospitalized), and pain and discomfort at the time of treatment.

6. I wonder if Sir Cecil Wakeley and Mr. Peter Childs would still say that "surgical excision is the method of choice for the deeper basal-cell carcinomata" if they saw, as we frequently do, patients with from one to two dozen or more lesions on the face alone.

7. The average patient, particularly if elderly, will almost invariably prefer removal of a lesion with irradiation in preference to surgery because of the natural aversion to "the knife" inherent in most people. For this and many other reasons the term "condemned to radiation" would be very appropriately replaced by "condemned to surgery."

8. I agree that the amenities for surgery, etc., are more generally available than adequate radiation facilities, but this fact is to be deplored rather than used as an argument for recommending surgery for all basal-cell carcinomata.

9. Irradiation is also "directed to the area involved and no more." Owing to the inverse square law and radiation quality employed very little radiation need go much deeper than a treated lesion, and not all or the main bulk of it as is inferred by Sir Cecil Wakeley.

10. I have seen a far greater proportion of recurrences after surgery than correctly applied irradiation, not only in Australia but in Great Britain and the U.S.A. Also I would be more than interested to know how "the extent of the excision" or area to be treated is more readily gauged with surgery than irradiation.

11. Sir Cecil Wakeley states that "the extent of a growth may not be appreciated without surgical excision." How can any man or his knife appreciate, see, or find every individual cancer cell and its distance from the clinically visible and palpable margin of any tumour? In point of fact an inadequate area is far less likely to be irradiated than excised, and the cosmetic result is generally far superior with irradiation.

12. The majority of small lesions can be treated with one dose of *x* rays in a matter of ten to fifteen minutes with no pain or even discomfort. Compare this with a local anaesthetic, the inherent distaste for the knife in almost every individual, and the presence of sutures which have to be removed later, and I think the issue of mental trauma needs no further comment. For larger and deeper lesions patients should be admitted to hospital if they receive surgical treatment, whereas they can be treated as out-patients by fractionated *x* radiation. Here again I would ask which method would occasion the most mental trauma.

—I am, etc.,

Sydney. JOHN C. BELISARIO.

Portal Hypertension

SIR,—In an annotation (July 30, p. 273) you quote Dr. R. R. Linton's operative mortality for spleno-rectal anastomosis in patients with hepatic cirrhosis as 71% (*Surg. Gynec. Obstet.*, 1948, 87, 129). He kindly sent us his figures up to the end of 1948, which I quoted at the recent B.M.A. meeting at Harrogate. As they have improved very considerably since the publication you quote, I give them hereunder in tabular form.

Condition	No. of Cases	Deaths	Mortality
Cirrhosis	21	7	33⅓%
Portal obstruction (extra-hepatic) ..	14	0	0%
Total	35	7	20%

During 1948 Linton operated on 20 patients with two deaths. I can testify that both these had very advanced hepatic failure.

May I raise one more point? The deficient coagulation of the blood is usually attributed to the introduction of sodium citrate. I do not know the evidence for this. We do know that many of these patients are deficient in prothrombin, and also that stored blood is deficient in this factor. As the prothrombin cannot be corrected in the presence of advanced hepatic disease, it would seem wise to use freshly drawn blood still potent in prothrombin when large transfusions may be needed. I believe therefore that the absence of the prothrombin is at least as important as the presence of citrate in the blood.—I am, etc.,

London, E.1. J. E. RICHARDSON.

Stress Incontinence in the Female

SIR,—Since the appearance of the article by Mr. Wilfred Shaw on the treatment of stress incontinence (June 18, p. 1070) I have watched your columns carefully for adverse comment. That none has appeared may be because I am alone in believing that this condition can be cured by less formidable procedures than that described. With all the respect due to an accepted authority I suggest that Mr. Wilfred Shaw's operation is unnecessarily formidable both for patient and surgeon, although I am prepared to accept the opinion of those who have tried it that it is less so than it sounds. An operation is not to be rejected because it is difficult, but it should not be adopted unless it has been shown that simpler, safer procedures fail. Mr. Shaw produces no evidence that this has been done, nor in fact could he or anyone else do so, as there are several operations too recent in origin for any opinion yet to be given as to their efficacy.

No one who has followed up cases treated only by vaginal plastic operations doubts that some are never cured and many recur, but excellent results have been obtained by the Aldridge type of operation and also by the simpler retropubic fascial grafting procedures described by Millin and by Marshall. For the comparatively short time in which I have been practising it I have had no failures and no recurrences with the 20-minute bladder-neck fixation operation of Everard Williams. I shall regard this as the operation of choice if these results continue. In the meantime I use a suburethral fascial graft, except in those cases where dense adhesion of the urethra to the vaginal wall makes attempted separation dangerous, when the graft is jettisoned and the Everard Williams operation carried out.

Mr. Wilfred Shaw's note on the selection of cases is brief. If prolapse has been successfully treated by colporrhaphy but incontinence remains, an operation of the type under discussion is indicated. If the result as regards the prolapse is not good a further attempt by anterior colporrhaphy often cures the incontinence also. One of the newer operations is indicated as a primary procedure in cases of stress incontinence without generalized prolapse, always assuming, of course, that neurological cause has been excluded.—I am, etc.,

Manchester. WALTER CALVERT.

Stress Incontinence in Disseminated Sclerosis

SIR,—In April, 1949, I was asked to see a patient aged 54 with disseminated sclerosis. In addition, probably as part of the disease, there was urinary stress incontinence which was getting worse. This was brought on by any effort, especially by coughing and sneezing. However, the patient stated she rarely passed a night without a wet bed, the bladder emptying itself during sleep. Her husband was very keen to have something done for her; he pointed out that as long as he lived she would be all right, but she was now becoming older and if he died before her it might be difficult to find someone willing and able to look after a patient with her great disabilities.

She had been under treatment for her disseminated sclerosis at intervals for the past 33 years. In 1938 or 1939 she was examined by a surgeon and told nothing could be done, and was fitted with a special apparatus to hold the urine. This proved useless, however. Earlier in 1949 a ring pessary was fitted, and she had also been given six weeks' electrical physiotherapy to the lower abdomen in the hope this would stimulate control, but neither treatment produced any improvement.

On examination, she was found to have a slight cystocele which was accentuated by coughing. Her pelvis appeared otherwise normal. On May 2 an Aldridge-type sling operation was performed without difficulty. The self-retaining catheter was kept in until the eleventh day after operation. After its removal there was rather more difficulty with micturition than usual after this operation. Frequent passage of a catheter caused a certain amount of infection, which responded to treatment. Filling of her bladder caused acute discomfort, no doubt partly due to the many years during which her incontinence prevented any bladder distension. At the end of one month, however, she had complete control. A severe cold and cough six weeks after operation caused a recurrence of frequency and bladder discomfort, but her incontinence remained controlled and, as she said, proved to her and her husband that she really was cured.

This case is reported so early after the operation because of the apparently very satisfactory result obtained by the treatment of this one disability in a patient with this distressing nerve disease.—I am, etc.,

Bristol. M. F. POTTER.

Spermatolysis

SIR,—Dr. Cafer Yildiran (April 2, p. 575) reports the occurrence of lysis of spermatozoa in the semen of five out of 75 men he examined. Spermatolysis resulting in disappearance of all spermatozoa from the ejaculate was described as occurring after two hours in two cases, after five hours in one, and after six hours in the remaining two cases. The fluid obtained by prostatic massage in two of these cases caused lysis of spermatozoa in normal control specimens. It is suggested that spermatolysis may be a cause of male sterility.

A series of 314 successive seminal specimens submitted to the Family Planning Association laboratory for routine analysis were examined for this feature. Twenty-two of these were "repeat" tests—i.e., the ejaculate of 292 men was examined. As Dr. Yildiran suggests that the factor causing spermatolysis might also be the cause of other seminal abnormalities, special attention was directed to a group of specimens showing oligozoospermia and other gross defects.

The quality of specimens in this series was as follows: group 1, total azoospermia, 24 cases; group 2, oligozoospermia

(under five million/ml.), 37 cases; group 3, subfertile and border-line, 187 cases; group 4, normally fertile, 44 cases. The age of specimens was as follows: group 1, six specimens produced at laboratory and inspected immediately, six specimens less than 1 hour old, and 12 specimens 1–2 hours old; group 2, 13 specimens produced at laboratory, and 24 specimens 1–2 hours old; groups 3 and 4, 61 specimens produced at laboratory, and 170 specimens 1–2 hours old. These specimens were kept under observation from the time received for periods of 6–24 hours. Specimens showing total azoospermia were mixed with part of others containing spermatozoa and kept under similar observation.

No spermatolysis was observed in any of the above 292 cases. In view of this finding, and in view of the fact that we cannot recall seeing a case suggesting spermatolysis in more than 5,000 previous semen analyses, we conclude that if spermatolysis occurs in this country it must be very uncommon. However, spermatolysis might be a phenomenon confined to other racial or climatic conditions, and it would be of great interest to hear whether Dr. Yildiran's findings have been confirmed elsewhere.—I am, etc.,

London, S.W.1 H. A. DAVIDSON.

B.C.G.

SIR,—Dr. W. Norman Taylor (April 30, p. 778) asks, "What are the facts?" And then, after discussing the significance of a positive reaction to the Mantoux test, concludes that by analogy with other diseases we can suspect that it may indicate resistance but that we can be by no means certain as yet.

Is not the case for B.C.G. much stronger than Dr. Taylor's letter implies? Heimbeck[1] was the first to show that healthy tuberculin-positive young adults were less susceptible to tuberculous disease than were those initially tuberculin-negative. Both Heimbeck[2] and Ferguson[3] have significantly lowered the incidence of clinical tuberculosis in tuberculin-negative nurses as compared with unvaccinated controls. In Ferguson's series there was actually less disease among the vaccinated than among those initially Mantoux-positive (those who "have been tried in the fire and not found wanting," according to Dr. Taylor).

Owing partly to the difficulties of conducting a perfectly controlled experiment over a period of many years in civilized communities, both these studies have been open to criticism, but on different grounds. However, Aronson's[4] study amongst 3,000 young Mantoux-negative American Indians appears conclusive to most critics. Nearly all those vaccinated became Mantoux-positive within a few weeks, and only six of them had died from tuberculosis after nearly 10 years, as against 53 of the unvaccinated controls.

It has been asked, "Could the same spectacular results be expected in civilized countries?" Studies like those of Heimbeck and Ferguson and the clinical experience of eminent Scandinavian physicians like Wallgren[5] indicate the answer. The Danes, who practise B.C.G. vaccination more extensively and thoroughly than any other people, have the lowest tuberculosis mortality in Europe (about 30, as compared with more than 50 per 100,000 in Great Britain).—I am, etc.,

Melbourne, Australia. E. A. NORTH.

Treatment by H 11

SIR,—I wish to protest strongly against the grossly unfair references to H 11 made by Dr. P. H. Phipps (July 9, p. 100). Reprints of articles published in the medical press have been sent to selected members of the medical profession, and in most cases the doctors concerned already have had experience of H 11 therapy.

A case is quoted in which she states that H 11 was tried out in hospital and failed. The truth is that H 11 was first given to this case on Sept. 2, 1943, and 13 days later, on Sept. 15, was stopped. The patient died 5 days afterwards on Sept. 20. Obviously this was no trial or failure of H 11. Indeed, on Sept. 24 the assistant medical officer wrote, "As his period of survival was so short one can hardly express any opinion as to the effect of the H 11 injections."

Further, the allegation is made that these Laboratories refused personal investigations and treatment of the patient. The facts are that the necessary supplies of H 11, with instructions, were dispatched to the hospital on the same day that a telephoned request was received for a supply. The Hosa Laboratories requested further details about the patient, and the correspondence, which can be seen, demonstrates the personal and detailed interest of these Laboratories throughout the brief period under review, as well as the helpful and courteous collaboration of the medical staff of the hospital.

Lastly, although many cases of inoperable cancer have recovered under H 11 treatment, no claim or even suggestion has ever been made by these Laboratories that H 11 is as yet the cure for cancer. The only claim made is that in advanced inoperable cases with an expectation of life of over two months an inhibitory action is demonstrable in 66% of cases treated—which claim can be verified by any careful and full investigation of our records.—I am, etc.,

Hosa Research Laboratories, Sunbury-on-Thames. J. H. THOMPSON.

SIR,—I received to-day, with the compliments of the Director of Research, Hosa Research Laboratories, a reprint of an article from the *Medical World* by Dr. Gordon Ward entitled "The Truth about H 11." Among other things discussed in this article is a list of 12 cases "selected by the Hosa Laboratories . . . as the most favourable in their files."

There are apparently between 3,000 and 4,000 histories of cases treated with H 11 in the files of the Hosa Laboratories. Survivals in the 12 cases cited have been for 7, 6, 4½, 4, 3, 3, 3 years, 18, 16, 16, 13, and 13 months respectively. If all these cases are accepted as cured (and this is not claimed) the cure rate would be between 0.3 and 0.4% of cases treated, while the 5-year survival rate would be 0.05 or 0.06%. Before one can judge the value of such survivals it is essential to know whether similar survival rates exist among untreated "inoperable" cancer cases.

It is a curious feature of almost every new method of treatment for cancer that has been advocated that a few cases have given apparently successful results while the great majority show no benefit. It would be interesting to know of any cases of cancer, classified as inoperable, of unexpectedly long survival which have had no further treatment or only symptomatic treatment. In the absence of knowledge on this point it is clearly impossible to form a fair judgment as to the possible value of treatment with H 11.—I am, etc.,

Glasgow. P. R. PEACOCK.

Parotid Emphysema During Labour

SIR,—A brief report of a somewhat unusual case of parotid emphysema might be of interest.

The patient, a primipara aged 20 years, was in bed in a maternity home suffering from a mild toxaemia of pregnancy. At 11.30 p.m. on June 25 she went into labour. She did not ring for the midwife until 5 a.m. on June 26, when she was found to be fully dilated. She therefore had no sedation or analgesia. By 7 a.m. she had made no further progress and she was delivered easily by forceps following episiotomy. She had gross bilateral swelling of the parotid glands when I saw her at 7 a.m. This was subsiding in 24 hours and was clear by June 28. Associated with this swelling was marked bilateral conjunctival haemorrhages. The patient was afebrile, had had mumps previously, and there had been no possible contact during the previous four weeks. This girl must have undergone very considerable physical effort, and in the course of this air must have been forced up Stensen's ducts.

As a footnote, I met a case of self-induced parotid emphysema during the late war. A soldier, on draft for overseas, attempted to evade the issue by blowing strenuously into a gingerbeer bottle, inducing parotid swelling, and then reporting sick, complaining with considerable craft of pain in his testicles. Such an effort almost deserved to succeed.—I am, etc.,

Bournemouth. ALAN S. OGDEN.

Urea for Migraine

SIR,—Dr. Nevil Leyton (Aug. 6, p. 335) pleads for a serious attempt to treat sufferers from "*migrainous*" headaches, and mentions urea as a remedy to be tried in obstinate cases. May I go further and suggest the use of this drug as a first line of preventive treatment in every case, whether of recent origin or of long standing? It is surprising how many patients will derive considerable benefit, if not complete relief, from attacks.

The dosage advised is as follows: 20 gr. (1.3 g.) of urea in water three times a day for a week, followed by the same dose twice a day for two weeks and further treatment with a daily dose of 20 gr. for an indefinite period.—I am, etc.,

Birmingham. J. A. BROWN.

POINTS FROM LETTERS

Retained Placenta

Dr. W. D. G. TELLAM (Penzance) writes: You have published many letters on the treatment of retained placenta, but it appears to me that such an emergency need never arise—unless it is that very rare placenta accreta. In a semi-rural domiciliary practice I have found the intravenous injection of 0.25 ml. of ergometrine given as soon as the head is born and the anterior shoulder delivered, followed 30 seconds later by the delivery of the posterior shoulder, results in the delivery of the placenta immediately afterwards—leaving a firmly contracted uterus. Our breech deliveries have received a similar intravenous dose as soon as the head is born, followed 30–45 seconds later by an intact placenta and membranes. I would like to know if this treatment of the third stage has failed or has caused any complications.

New Problems of Rheumatism

Dr. THOMAS ROBERTSON (Glasgow) writes: In your leading article (July 23, p. 221) you quote Hench as stating that there are 200 arthritic and musculo-skeletal conditions called rheumatism. This raises a number of important questions. By what criteria are these differentiations made? In such a context as the above, does the word rheumatism signify anything? Apparently one can develop any of the 200 types either as a disease in the body ("soma") or in the "psyche." Dr. W. S. C. Copeman (p. 191), who now comes forward with another aetiological variety of rheumatism, provides a quasi-mechanical explanation concerned with water metabolism and fatty tissue. He suspects, probably rightly, that the hypothalamus may be at fault. But what relation exists between the hypothalamus and this mysterious "psyche"? However—to come to earth—as a physician of the baser sort I am delighted to find (1) that fibrositis no longer exists, (2) that most cases of rheumatism met with in practice cannot be either understood or adequately treated unless the patient is not only physically but psychologically examined, as Halliday pointed out in the *Journal* (1937, 1, 213 and 264), and (3) that physiotherapy frequently does more harm than good.

Psychogenic Rheumatism

Dr. I. ERNST REICHENFELD (Birmingham) writes: Drs. William Tegner, Desmond O'Neill, and Anna Kaldegg (July 23, p. 201) gave an interesting analysis of a number of those unfortunate people with vague but for them very real complaints who are familiar to the G.P. Valuable as their paper is, I found the title "Psychogenic Rheumatism" rather misleading. In my opinion the expression "rheumatism" ought to be reserved for the two conditions which are more or less well defined entities—viz., rheumatic fever and rheumatoid arthritis. If we call every painful condition for which we cannot find a cause rheumatic we follow the rather vague nomenclature of the lay public and confuse the latter even more. That a cervical rib is being called a "rheumatic complaint" obviously is an oversight.

Percussion Finger

Dr. A. NIVEN ROBERTSON (Edinburgh) writes: For thirty years of my life I was engaged continuously in the examination of chests, and therefore I was daily percussing the dorsum of the middle phalanx of the middle finger of my left hand. As a result of this constantly recurring trauma I noted a distinct smooth, low, and firm swelling had been created on the dorsum of that phalanx. The swelling was scarcely noticeable to the eye, but it was quite obvious to palpation. It had a convex surface and shaded off on to the bone at its upper and lower curved ends. It was never painful. For the last seven years I have rarely done any percussion and the swelling has to all appearances disappeared. I shall be interested to know if other percussionists have found the same thing. The swelling was obviously a fibrous hypertrophy due to constant mechanical trauma.

Obituary

SIR ALAN NEWTON, M.S., F.R.C.S., F.R.A.C.S., F.A.C.S.

On Aug. 3 Australia lost one of her most distinguished sons—a great surgeon—Sir Alan Newton.

Hibbert Alan Stephen Newton was born on April 30, 1887, and was educated at Haileybury College, Melbourne, and at the University of Melbourne. He was a brilliant student, and in his final year was placed first in a distinguished company. He was very early attracted to surgery, which was to give scope not only for his natural and acquired manual dexterity, aided by a splendid visual knowledge of anatomy, but for his sound judgment and the decisive quality which characterized all his thinking.

He qualified in 1909, and after a year as resident at the Royal Melbourne Hospital and a further period as surgical registrar he became associated with Mr. Fred Bird, who had operated on him early in his course and from whom he learnt much of the art of surgery. He took the M.S. in his own university in 1912. In 1913 he was appointed an out-patient surgeon at the Royal Melbourne Hospital. The period immediately before this appointment was spent not in acquiring further qualifications but in postgraduate study and research in England, where he came under the influence of Sir Victor Horsley and saw much of his friend, the late Dr. Gordon Clunes Mathieson, who was then working with Professor Starling at University College Hospital.

Apart from this brief absence and a longer one during the 1914–18 war, all his working life was spent in close association with the Royal Melbourne Hospital until he retired from the active staff and became an honorary consultant surgeon. During the first world war he served in France as a surgeon in the Australian Army Medical Corps. In 1919 he became a Fellow of the Royal College of Surgeons, England. Subsequently, he was elected a Fellow of the American College of Surgeons, an Honorary Fellow of the British Association of Surgery, and an Honorary Fellow of the Royal Society of Medicine.

Newton's ancestry, with many distinguished lawyers in his family tree, might have led him to the practice of law, but indeed his talents were such that he would have made a success of any profession. He was a splendid teacher—a master of lucid exposition. Always a ready speaker, for any special occasion he would carefully prepare his speech and in doing so memorize it. This gift of oratory was displayed on many occasions, notably in his Stawell Oration and in an address to his colleagues and friends at the Royal Melbourne Hospital dinner on "The Spirit of the Place."

Newton was keenly interested in the teaching of student and after his return from the first world war, in additio to his regular hospital clinics, he became a lecturer i surgery at the University of Melbourne, and at a lat stage took the chief position as Stewart Lecturer orgar izing the surgical teaching. He had a strong belief i

the importance of carefully planned clinical lectures in which people of experience could provide for the students material not readily to be obtained in textbooks. He was deeply interested not only in undergraduate but also in postgraduate teaching, and played an important part in forming the Melbourne Permanent Postgraduate Committee, whose object was to increase the facilities for postgraduate teaching in all departments of medicine and surgery. He was a Foundation member of the Royal Australasian College of Surgeons, and in its early years was Censor-in-chief and subsequently its President. His unselfish and unsparing efforts to improve the status of the surgical profession in Australia were extremely fruitful. For his work for the College he was knighted in 1936.

During the second world war Sir Alan served with the rank of colonel in the Australian Army Medical Corps, being consulting surgeon to Army Headquarters for two years. From 1940 to 1945 he was chairman of the Medical Equipment Control Committee, Department of Defence, and in this capacity he made a major contribution to the Australian war effort. He brought to bear on the problem of medical equipment and drug supplies a clear analytical mind that saw the position in its true perspective and assessed priorities in their right order. In January, 1942, the paramount importance of immediately getting more quinine out of Java was realized by the Australian military authorities, who had just arrived there. Within 24 hours of Sir Alan Newton's receiving this secret information a very large sum was made available by the Australian Government in a Dutch bank in Batavia to procure 120 tons of quinine: such was his capacity for rapid decision and prompt action and the influence he exerted at the highest level even as early as 1942. His co-operation with Army Headquarters in speeding up the manufacture of essential drugs like sulphaguanidine was of the utmost value to both the South-west Pacific and the South-east Asia Commands. Nor were his activities limited to the field of surgery. His status stood almost as high in the financial as in the surgical world. His reputation for probity, sound judgment, and business acumen, and his wide knowledge of men and affairs, made him much sought after, and he was later on the board of directors of several of the leading companies of Australia.

Be surgical technique never so great, reputation outlives the man by very little. The only immortality for physicians and surgeons lies in the extent to which they lay foundations for their students and their successors. Alan Newton followed what was best of tradition but had no patience with its "dead hand." He saw that hospitals and medical schools could be too self-contained, that it should be possible to share what was best in one with others, and that this might be reciprocal. After the second world war, despite chronic ill-health, he attempted to apply these principles to the three teaching hospitals of the Melbourne Medical School, and this remained his chief interest until the end of his life.

Alan Newton was a dynamic person. His character was solid as a rock. He never sat on a fence, and for him there were no grey shadows. His clear insight and objective approach to problems made his opinion much valued. In him imagination and vision were blended with the capacity to adapt them to practical ends. Though intolerant of stupidity or muddle-headed thinking, he had the virtue of being intensely critical of his own conclusions and was always prepared, on the rare occasions on which events showed him to be wrong, to admit his mistakes. He would never undertake anything unless he could do it well, and everything he did was superlatively well done.

He married in 1919 Mary Cicely, daughter of J. Hartley Wicksteed, of Weetwood, Headingley, Yorks, who, together with a son and a daughter, survives him.—T.P.D., N.H.F., and C.H.K.

Dr. Isaac Jones and Mr. E. T. C. Milligan write: Many to-day in this country and Australia will have a sad sense of loss with the passing of Sir Alan Newton, but there will come a greater sense of gratitude and satisfaction for the gift of such a man in our life and generation. He was a wise and warm friend, an inspiring leader, and a stirring example. He inherited, and acquired through his home training, high moral standards, the art of creative human relationships, and a strong sense of selfless duty and responsibility. He began as a leader in his academic career, and with his outstanding abilities he naturally took the lead even amongst a unique generation of leaders and talented men. He ever maintained this leadership in the wider sphere of professional and social life. This pioneering leadership gave him an air of austerity and dignity, but it was a thin veneer over an open and affectionate heart, which it was the delight of all his friends to discover. How he raised Australian surgery by his vision, example, and planning to the high place it now holds in British surgery will for ever place him among the leaders and prophets of that young country; but those of us who were trained with him and lived alongside him will ever be grateful for the man, his standards, and his inspiration and encouragement.

His main vocation in life was to help his fellow men in the inevitable hour of suffering and personal crisis. In recent years he too had to face the common ordeal of suffering and death, the ultimate test of a man's philosophy of life. In recent letters there was the unmistakable fighting note of triumph and hope, revealing that the inspiration of his whole life came from his knowledge and possession of the same spiritual resources and verities which inspired his notable ancestors.

An Australian colleague writes: By the death of Sir Alan Newton, Australia has lost one of her leading surgeons and a man who did all in his power to follow and teach in his own land what he felt to be best in British surgery. After qualifying and holding several house appointments at the Royal Melbourne Hospital he visited England and worked with Sir Victor Horsley at University College and Queen Square on shock injuries to the spinal cord, at the same time studying the advances of British surgery. When the first world war drew to a close he was one of the selected men brought to this country to do postgraduate work in addition to their Army responsibilities: he obtained his F.R.C.S. in 1919. The two periods of work in England had a great effect on Newton's future life and work, for he carried home with him an admiration for what he had seen and learnt and a determination to reproduce in his own country and hospital those things which he felt were true, honest, just, and of good report. Thus in later years he became a prime mover in establishing, and was a Foundation Fellow of, the Royal Australasian College of Surgeons, filling the positions of Censor-in-chief, Vice-president, and finally President in 1942–5. Between the wars Newton steadily built up a wide reputation as a careful and skilled surgeon and was perhaps best known for his work on goitre. As a teacher, in classroom or in ward, he was clear, accurate, and concise, and had no difficulty in holding his audience. In addition to many contributions to scientific journals he was much sought after as the speaker on special occasions. The Lister Oration on toxic goitre in 1938, and his tribute to his old teacher Sir Richard Stawell in October, 1947, will remain in the memory of

those who heard them. He said of Stawell that he was at times "perhaps a little unrestrained in his criticism . . . but nobody minded this much." The same could be said with equal truth of Newton. Honest endeavour pleased him, but he could not suffer slackness in silence. The beginning of the second world war found Australia in a dangerous position as regards medical and surgical supplies, dependent as it was on overseas shipments. Newton was appointed chairman of the Medical Equipment Control Committee and did a fine piece of work. Under his enthusiastic guidance a workshop built to make railway equipment produced surgical forceps, scissors, and the like. He was trusted by the members of his profession, and they put up cheerfully with the restrictions he imposed, for all recognized his honesty of purpose and fairness. Tall, trim, and alert, he commanded respect, but his patients and those he honoured with his friendship experienced kindness beyond the ordinary, courtesy, consideration, and good humour on all occasions. He will be sorely missed, and he leaves many cherished memories behind him in addition to admiration for his services to his country and his profession, for he was a big man in every way.

W. G. WILLOUGHBY, M.D., D.P.H.

Dr. W. G. Willoughby, Past President of the British Medical Association and formerly medical officer of health for Eastbourne, died on Aug. 13 at the age of 83.

Until William George Willoughby was introduced at the Annual Business Meeting of the British Medical Association in London in 1930 his name was little known to the medical profession outside Eastbourne. He was content with a local reputation, but that was a very high one. By the practitioners of Eastbourne, whose unanimous choice he was for the presidency of the Association, no man was more highly regarded. His election as President was something new in Association history, for he was the first whole-time medical officer of health to be its titular head. But he himself, as he said in his address at the Eastbourne Meeting in 1931, was anxious that not too much should be made of that singularity, for he thought it emphasized a cleavage which should have no real existence. Probably he would have described himself as a general practitioner as much as any of them, and equally he would have called his colleagues in general practice practitioners of preventive medicine. For him medicine was not bisected into the curative and the preventive, and it was his vision of its wholeness—a vision he had translated into administrative detail during nearly half a century—which accounted for much of his popularity among the medical profession in his area.

W. G. Willoughby was a son of Devon, but he had been for so long associated with Sussex as to be a part of its personality. He received his medical training at St. Bartholomew's (where his younger brother, the late Dr. W. M. Willoughby, M.O.H. for the City of London, followed him) and qualified in 1888. After a resident appointment at his hospital and some period of study in Vienna he became, within five years of his qualification, medical officer of health for Eastbourne, in which post he remained for forty-five years. On his retirement in 1939 he was the senior medical officer of health for any county or county borough as regards length of service. He had seen Eastbourne grow from a small place of not more than five thousand inhabited houses to a spreading resort with more than three times that number.

At the time he began his work few public health services were in existence or were in more than rudimentary form. Indeed, Eastbourne came in for a good deal of criticism just when Willoughby was getting into the saddle. This *Journal* had an acid note in 1896 that Eastbourne had rather too good a conceit of herself in respect of her sanitary conditions. It was said to be more by good luck than by intelligent management that she had escaped a visitation of smallpox that would have brought her growth to a premature end. It was also suggested that an improvement in the quality of her water supply and the purification of her sewers "might profitably engage the attention of those who have the public health of the place in their keeping." Under W. G. Willoughby's guidance Eastbourne became from the sanitary point of view one of the most progressive places in the kingdom.

The long years of service for Eastbourne were broken only by the war of 1914–18, in which, after serving in Egypt, he became malaria officer in Macedonia and eventually Acting A.D.M.S., Sanitary, to the 12th Army Corps. After the war he gradually took a more prominent place in the central affairs of his profession. He became President of the Society of Medical Officers of Health and of the Medical Officers of Schools Association, as well as of the Eastbourne Medical Society. He was called to the presidency of the British Medical Association at its ninety-ninth meeting, and in the preparations for the Centenary he took a prominent part. Some of the ceremonial of the Centenary celebrations fell to him, notably the unveiling of the tablet on the Sir Charles Hastings house during the Worcester Pilgrimage. After his presidency he continued for eight years to be a member of the Council, interesting himself in many Association concerns, but especially those which bore on public health. He was a member of the Public Health Committee for many years and chairman of the special committee which dealt with the relation of alcohol to road accidents. At the Annual Meeting at Winnipeg in 1930 he was vice-president of the Preventive Medicine Section, and at Oxford in 1936 of the Section of Medical Sociology. He had also served as chairman of his Division in 1928–9 and president of his Branch in 1929–30. He was twice an M.D., having taken the London degree in 1889 and the M.D. in State Medicine in 1894. While his main interest was in public health and in balneology it extended also to other fields—to psychology, for example, on which he contributed several articles to Tuke's *Dictionary of Psychological Medicine*.

Like other public servants whose principal work is to prevent, his achievements are not among those that leap to the eye, but they were appreciated in the place where he laboured, and by none more than his medical colleagues. They subscribed to a handsome testimonial on his retirement, on which occasion he was also presented with the freedom of the borough. In his valedictory, addressed to the mayor and corporation of Eastbourne, he said: "Without the good will of the medical profession it is not possible for the public health services of the country to be carried out satisfactorily. I am very grateful, therefore, that in Eastbourne there has been full co-operation between medical practitioners and the public health department."

Those who had the happiness to be associated with him will long remember a most kindly and modest personality.

SAFE SULPHONAMIDE THERAPY

with

'SULPHAMEZATHINE'

(Sulphadimidine)

During recent years a number of eminent authorities have expressed a preference for 'Sulphamezathine' and have drawn attention to its outstanding advantages in the treatment of bacterial infections.

The following special characteristics of 'Sulphamezathine' administration are of importance in medical practice.

'Sulphamezathine' is one of the least toxic of the sulphonamides. It is well tolerated and rarely produces unpleasant effects of any kind.

Renal complications are almost unknown. Additional fluids and alkalis are unnecessary.

Excretion of 'Sulphamezathine' is relatively slow, so that effective blood levels can be easily maintained.

'Sulphamezathine' is available in the form of tablets (0.5 gramme), lozenges and oral suspension; as a powder; and as the sodium salt in sterile solution for parenteral administration.

ANAHÆMIN for routine use

For most cases of pernicious anæmia, whether complicated with subacute combined degeneration of the cord or not, Anahæmin is the preparation of choice for effective treatment. This is acknowledged by the pre-eminent position held by Anahæmin for more than a decade.

ANACOBIN BRAND Crystalline Vitamin B_{12} for the hypersensitive patient

Occasionally, cases of pernicious anæmia arise which cannot be treated satisfactorily, even with Anahæmin, because of hypersensitivity. These cases are remarkably infrequent when Anahæmin is employed. For the treatment of such cases, 'Anacobin,' a solution of crystalline vitamin B_{12}, an anti-pernicious anæmia factor present in Anahæmin, is now available. A typical case in which vitamin B_{12} B.D.H. was employed successfully was reported in the Lancet, June 25th, 1949, p.1119.

(It is regretted that owing to limited supplies samples of 'Anacobin' cannot be made available.)

Oral therapy for urogenital analgesia . . .

'PYRIDIUM' administered orally in a dosage of 2 tablets t.i.d. promptly relieves such symptoms as painful, urgent, and frequent micturition, nocturia, and tenesmus. 'Pyridium' acts directly on the mucosa of the urogenital tract; its characteristic analgesic effect is entirely local, and it is not associated with or due to systemic sedation or narcotic action. Therapeutic doses of 'Pyridium' may be administered with virtually complete safety in most cases of infection or irritation of the urogenital tract.

MENLEY & JAMES, LTD., 123 COLDHARBOUR LANE, LONDON, S.E.5

JOHN PHILLIP HENRY DAVIES, of Elgin, Llanishen, near Cardiff, died suddenly on July 19, while on holiday. A member of one of the oldest and best-known medical families in South Wales, he was born in Ystrad Rhondda in 1883, the son of Dr. I. Naunton Davies, who practised there for many years and who was an outstanding public figure. Dr. Davies received his medical education at Cambridge University and St. Bartholomew's Hospital, qualifying in 1910. A year later he took the D.P.H., and in 1914 the Cambridge degree of M.B. After a term as house-physician to the London Chest Hospital he was appointed assistant medical officer of health for the Rhondda Urban District Council. In the first world war he served in the R.A.M.C. in the Second Welsh Field Ambulance with the rank of captain. After demobilization he went into general practice in Llanishen, succeeding the late Dr. Shiach there, and very soon he gained the confidence and high regard not only of his many patients but also of all his professional colleagues. Among the appointments that he held were those of medical officer to the Post Office and clinical assistant to Cardiff Royal Infirmary, while he was honorary surgeon to St. John's Ambulance Brigade and an Officer of St. John of Jerusalem. He was secretary of the Section of Pharmacology and Therapeutics at the Annual Meeting of the Association at Cardiff in 1928. In all of these offices he gave of his best. A conscientious and able practitioner, he was of a singularly simple, direct, and attractive disposition, while his temperament was remarkably equable, so that he was never ruffled or out of temper. His ethical sense was of the highest, and in this and in other aspects of his character there was much of that strict sense of duty that we associate with the "old school." No one ever had a hard word to say about "J.P.H.," as he was affectionately known. His genial personality will long be missed. He leaves a widow, one son who recently graduated in medicine from Bart's, and two daughters. The deep sympathy of a wide circle of friends and admirers is extended to them in their great bereavement.

Dr. ALFORD WILLIAM ANDERSON died at his home at Dalbeattie, Kirkcudbrightshire, on July 25 at the age of 81 after an illness of several months' duration. He graduated M.B., C.M. at Edinburgh University in 1891, and after serving as resident medical officer at Fife and Kinross Mental Hospital he took up general practice at Dalbeattie in 1894. In 1908 he proceeded M.D. For almost forty years he carried on an extensive country practice single-handed, and retired in 1935, when he was honoured by a public banquet. The welfare of his patients was always his first consideration, and his kindly manner, added to his very considerable experience and skill, was a constant comfort in this widely scattered community. From his earliest days in Dalbeattie the local volunteers claimed his attention, and he received a commission shortly after going there; he was instrumental in raising the company to full strength. In August, 1914, he was mobilized with his battalion, the 1/5 K.O.S.B., but was later transferred to the R.A.M.C., attaining the rank of lieutenant-colonel. On return to civilian duty he became an enthusiastic member of the British Legion, and was the first president of the local branch, an office he held with distinction for many years until illness supervened. It was largely due to his efforts that the Dalbeattie branch of the Legion received the gift of the allotment grounds and entrance gate. During the recent war he was Medical Examiner of Recruits and Troop Relation Officer in the area. His recreations were shooting and fishing, in which he was an expert, and his congenial company and good sportsmanship were ever an asset. He was a pioneer in motoring and one of the first in Dalbeattie to own a car. Predeceased by his wife, he leaves a family of two sons and three daughters. The profession has lost a fine representative of the old type of general practitioner, who will be much missed by all who knew him.

Professor CAMILLO WIETHE, director of the Second University Clinic for Otorhinolaryngology in Vienna, died on July 10 at the age of 60. From 1927 to 1936 he had been assistant to Professor Hajek, the well-known laryngologist, and was in private practice from 1938 to 1945, when he was appointed director of the clinic. He had contributed to the medical press on many subjects, including burns of the oesophagus, the surgery of the larynx, and allergic conditions.

Universities and Colleges

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

M.D.—*Branch I (Medicine):* G. M. Bailey, D. H. Bennett, A. C. Boyle, H. W. Bunje, N. R. Butler, J. A. Chamberlin, C. E. Dent, H. E. de Wardener, I. R. Gray, K. G. Green, T. A. Grimson, K. J. Gurling, M. Hamilton, J. N. Harris-Jones, M. F. Hart, M. S. R. Hutt, Madeline K. Keech, D. R. Laurence, G. de J. Lee, G. H. T. Lloyd, J. Marks, D. B. Morgan, F. W. Nash, F. T. Page, Diana G. Paradise, R. G. Pitman, N. Ponnampalam, T. A. J. Prankerd (*University Medal*), D. L. Rees, T. A. Richards, M. Steel, S. J. Steel, P. G. Swann, D. M. E. Thomas, N. A. Thorne, L. H. Turner, E. Waddington, R. S. Walker, J. R. Wilson, W. J.-S. Wilson. *Branch II (Pathology):* Rosemary P. Biggs (*University Medal*), F. N. Ghadially, C. L. Greenbury, R. F. Jennison, Sylvia D. Lawler (*Mark of Distinction*), W. D. Linsell, C. F. Ross, C. H. Smith, H. E. Vickers, K. W. W. H. Walton, F. Whitwell. *Branch III (Psychological Medicine):* J. H. Rey, A. Shapiro, Fede M. Shattock (*University Medal*). *Branch IV (Midwifery and Diseases of Women):* J. D. Martin, N. F. Morris, A. C. Pearson. *Branch V (Hygiene):* Doris A. Craigmile, M. T. I. Jones. *Branch VI (Tropical Medicine):* D. Lawrence.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

The following scholarships have been awarded: *Anatomy and Physiology Scholarship,* J. S. H. Lodge (Emmanuel College, Cambridge); *Burney Yeo Bequest Scholarship,* H. T. Thomas (Jesus College, Cambridge); *Epsom College Scholarship,* Michael Dulake (Clare College, Cambridge); *Seaman Bequest Scholarship,* T. M. O. Morris (Trinity College, Cambridge).

UNIVERSITY OF MANCHESTER

William Sayle-Creer, M.Ch.Orth., F.R.C.S., has been appointed Honorary Clinical Lecturer in Orthopaedic Surgery.

The Council of the University has accepted the sum of over £200 from the subscribers to the fund raised in memory of the late Dr. William Susman, Lecturer in Morbid Anatomy and Histology from 1926–48. It is proposed to establish an annual prize in pathology, the first offer of which will be made in 1950.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The Council of the Welsh National School of Medicine has appointed William Ferguson Anderson, M.D., M.R.C.P., F.R.F.P.S., to the post of Senior Assistant in the Medical Unit of the Welsh National School of Medicine. Dr. Anderson is at present Lecturer in Materia Medica and Therapeutics in the University of Glasgow and Assistant Physician at Stobhill Hospital, Glasgow.

The Services

The President of the Czechoslovak Republic has conferred the Czechoslovak Military Medal, 1st Class, upon Air Marshal Sir Harold E. Whittingham, K.C.B., K.B.E., R.A.F., retired, in recognition of valuable services rendered in connexion with the war.

A notice appeared in the *London Gazette* dated Nov. 19, 1948, and in the *Journal* of Dec. 11, 1948 (p. 1043), stating that the King of the Hellenes had conferred the decoration of Commander of the Royal Order of the Phoenix upon Captain A. M. Boyd, R.A.M.C. The name should have read Lieutenant-Colonel (temporary) Alexander Michael Boyd, R.A.M.C.

The Efficiency Decoration has been conferred upon Major (Acting Lieutenant-Colonel) C. K. Sconce and Major J. M. Lees, R.A.M.C., T.A.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 30. [No. 30

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis and Polio-encephalitis

The notifications of these diseases were 70 more than in the preceding week. The largest returns during the week were: Yorkshire West Riding 24 (Leeds C.B. 5, Dewsbury C.B. 4, Colne Valley U.D. 2, Spenborough U.D. 2); London 20 (Camberwell 4, Kensington 3, Hampstead 2, Paddington 2, Southwark 2, Wandsworth 2); Middlesex 13 (Hornsey M.B. 6, Enfield U.D. 2); Lancashire 12 (Liverpool C.B. 6); Cornwall 8 (Camborne–Redruth 3, Penzance M.B. 2, West Penwith R.D. 2); Essex 8 (West Ham C.B. 2); Southampton 7 (Portsmouth C.B. 2); Warwickshire 6 (Birmingham C.B. 2, Coventry C.B. 2); Cheshire 6 (Winsford U.D. 3); Suffolk 5 (Bury St. Edmunds M.B. 2); Leicestershire 5 (Leicester C.B. 2).

In the week ended Aug. 6, 1949, notifications of poliomyelitis numbered 164 (147) and of polio-encephalitis 22 (22). (Figures for the preceding week are shown in parentheses.) Counties with multiple cases (poliomyelitis and polio-encephalitis together) were: London 31 (20), Bedford 5 (2), Berkshire 3 (2), Chester 3 (6), Cornwall 9 (8), Derby 2 (0), Devon 6 (1), Essex 7 (8), Gloucester 5 (3), Hertford 3 (3), Kent 3 (3), Lancaster 12 (12), Leicester 5 (5), Lincolnshire, Lindsey 4 (4), Middlesex 15 (13), Somerset 2 (0), Southampton 9 (7), Stafford 2 (1), Suffolk West 6 (4), Surrey 7 (1), Sussex West 2 (4), Warwick 5 (6), Yorks East Riding 2 (2), Yorks North Riding 2 (1), Yorks West Riding 17 (24), Glamorgan 5 (3), Monmouth 2 (2).

Some outbreaks with high attack rates in comparatively small communities are still being reported, but there is also a generalized rise in prevalence like that of 1947. Fortunately the notifications in the week under review are 301 fewer than those of the corresponding week of 1947. The figures are:

	Poliomyelitis	Polio-encephalitis
1947 week ended Aug. 2	448	39
1949 „ „ Aug. 6	164	22

Discussion of Table

In *England and Wales* a decrease occurred in the number of notifications of measles 786, whooping-cough 209, scarlet fever 112, acute pneumonia 66, while a rise was reported for acute poliomyelitis 51, acute polio-encephalitis 19, and diphtheria 22.

The largest decreases in the notifications of measles were Warwickshire 115, Lancashire 94, London 76, Cheshire 72, Kent 72, while the only exception to the general decreasing trend was a rise of 51 in Norfolk. A small fall in the incidence of scarlet fever occurred in every region of the country except in the eastern region, where there was a slight rise. No changes of any size were reported in the local trends of whooping-cough. The chief features of the returns of diphtheria were increases in Staffordshire, where the cases rose from 0 to 11 and involved eight administrative districts; Warwickshire, with a rise from 4 to 10 (Birmingham C.B. 9); Yorkshire West Riding, with a rise from 1 to 8, where the cases were spread through six administrative areas.

An outbreak of dysentery involving 18 persons was notified in Buckinghamshire, Amersham R.D. A further 14 cases of dysentery were notified from Warwickshire, Warwick R.D., bringing the total cases during the past three weeks to 81. The other large returns of dysentery were Lancashire 11 and London 10. Of the 50 cases of paratyphoid 30 were notified in Lancashire (Liverpool C.B. 21).

In *Scotland* decreases were recorded in the number of notifications of measles 29, acute primary pneumonia 20, dysentery 14, while an increase of 23 was reported for scarlet fever. Fifteen cases of poliomyelitis were notified, an increase of 8 on the number of the preceding week. The rise in the incidence of scarlet fever was mainly due to the northern and north-eastern areas.

In *Eire* rises occurred in the number of notifications of diarrhoea and enteritis 49 and whooping-cough 56, and a fall of 15 was recorded for scarlet fever. An increase of 56 occurred in the notifications of diarrhoea and enteritis in Dublin C.B.

In *Northern Ireland* an increase of 21 in the number of notifications of measles was the only change in the trends of

infectious diseases. The rise was contributed by the counties of Londonderry and Tyrone.

Week Ending August 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 854, whooping-cough 1,566, diphtheria 89, measles 3,683, acute pneumonia 220, cerebrospinal fever 19, acute poliomyelitis 164, acute polioencephalitis 22, dysentery 45, paratyphoid fever 37, typhoid fever 5.

Medical News

Awards by N.A.P.T.

The N.A.P.T. has awarded the following scholarships to Colonial medical personnel to enable them to spend a period in Britain studying anti-tuberculosis methods. Scholarships of £120 each to: Dr. R. K. Richardson (Trinidad), Dr. A. W. E. Moreira (Federation of Malaya), Dr. Abbas bin Haji Alias (Federation of Malaya), Dr. Mohd Din bin Ahmad (Federation of Malaya). Scholarships of £80 each to: Miss W. C. Jones, matron (Jamaica), Mr. See Ho Meng, male nurse and hospital assistant (Singapore). A prize of 100 guineas for an essay on the control of tuberculosis in a British Colony by a medical officer in the service of a Colonial Government has been awarded to Dr. Vincent Hetreed, of Northern Nigeria.

Scientific Films

The Third International Scientific Film Congress will be held in Brussels on Sept. 30–Oct. 5. In conjunction with the congress there will be a Scientific Film Festival at which medical films will be shown. The Scientific Film Association of Great Britain is considering the films to be submitted as the British entry in the festival. While the association knows of most of the important films, it would appreciate information about privately produced films suitable for inclusion. Full details should be sent to the office of the association at 4, Great Russell Street, London, W.C.1.

Pharmaceutical Conference

The Pharmaceutical Society of Great Britain will be represented at the Assembly of the International Pharmaceutical Federation in Amsterdam on Aug. 29–Sept. 2 by the president, Mr. H. Clement Shaw, Professor Brindle, Professor Todd, Dr. J. M. Rowson (who will read a paper at the Assembly), Mr. E. A. Brocklehurst, Miss M. A. Burr, Mr. J. F. McNeal, and Mr. F. W. Adams (secretary and registrar).

Tuberculosis Appointments in Italy

A number of appointments at the Ospedale Sanatoriale "Forlanini" in Rome and at the Ospedale Sanatoriale "Forlanini" in Naples are open to British medical practitioners who wish to learn Italian methods of treating tuberculosis. The appointments are tenable from Nov. 1, 1949, to June 30, 1950. Those holding them will receive full board and lodging at the hospital, but must pay their return fares and supply their own pocket money. Candidates should send their applications before Sept. 15 to the Controller, Education Division, British Council, 3, Hanover Street, London, W.1, giving particulars of their age, medical training and experience, and the names and addresses of two referees.

Progress Report on Cancer Research

A series of 15 articles on cancer research have been prepared by Mr. Lester Grant, a science writer on the staff of the *New York Herald Tribune*. They are designed to be an authoritative progress report on work in this field, and the United Nations Educational, Scientific, and Cultural Organization, 19, Avenue Kléber, Paris, 16e, has purchased them and is willing to make the whole series available freely to any journal or individual on request.

Manchester Paediatric Club

At the fifth meeting of the Manchester Paediatric Club on July 18 Professor Alton Goldbloom, professor of paediatrics at McGill University, Montreal, Canada, delivered an address on "Pitfalls in Paediatric Diagnosis." The second annual general meeting of the club will be held on Sept. 27.

National Institute for the Deaf

At the annual general meeting of the National Institute for the Deaf, held on July 6, the president, the Duke of Montrose, referred to the greatly increased work of the N.I.D., much of it due to the introduction of the Health Service. Thousands sought advice on all kinds of problems relating to new legislation. He emphasized the improvements necessary in the supply of hearing-aids under the Government scheme, and said that new and improved hearing-aids would soon be available. The chairman of the council, Mr. R. Scott Stevenson, said that the institute had become an active information bureau, with an average mail of some 400 letters a week. The institute was in constant touch with Government departments and organizations of many kinds. Mr. Edward Evans, M.P., vice-chairman of the N.I.D. and chairman of the National Advisory Council for the Welfare of Handicapped Persons, set up by the Minister of Health, pointed out that the Minister had stated categorically that welfare work could not succeed without the help of the voluntary societies. The State had therefore accepted the ultimate responsibility for the care of the handicapped, but left the human administration to those who by long experience and devoted service, coupled with technical efficiency, were best suited to administer that great conception of social service.

Funds for Peckham Health Centre

Lord Nuffield has offered £5,000 to Peckham Health Centre if other subscribers give the same amount. The health centre states that subscriptions have now nearly reached the required figure, but further contributions are urgently needed. One way in which funds can be raised is through the health centre's *Bulletin*, since the costs of publication and postage have been defrayed by a friend. The *Bulletin* costs 7s. 6d. a year, and is obtainable from 8F, Hyde Park Mansions, Marylebone Road, London, N.W.1.

Health Education

At the 22nd annual general meeting of the Central Council for Health Education, held on July 28, Lord Woolton was re-elected president and Sir Allen Daley and Dr. Charles Hill vice-presidents. Dr. E. K. Macdonald, medical officer of health for the City of Leicester, was reappointed chairman of the council, and Dr. W. A. Bullough, formerly county medical officer of health for Essex, and Dr. Robert Forgan were also re-elected as vice-chairman and honorary treasurer respectively. In his report for the year Dr. Macdonald said that in spite of the reduction in the grant from the Ministry of Health the council had been able to maintain its equilibrium and to introduce several promising and significant developments. During the year the Central Council had organized three series of short refresher courses at 12 university centres in England, Wales, and Northern Ireland. They had proved so successful that the council proposed to make them a permanent feature of its free services and to extend their scope considerably. The council had also considered what it might do to relieve the very heavy burden on general practitioners working under the Health Service. It was planning a series of small leaflets on specific disorders, which general practitioners would be able to hand to patients at consultation. These leaflets would contain information about diet, etc., which would supplement the physician's verbal instructions, and which the patient could keep for reference. The scheme would be operated in conjunction with local authorities. He also referred to possible changes in the constitution of the council, which would probably give a predominant influence to local authorities. It would perhaps mean the severance of some old ties, but it would give the council a more official standing and greater financial stability and thus enable it to continue to exercise a growing influence on the development of health education.

Commendation for Bravery

Dr. Eric Buchanan Ross, general medical practitioner, Cambois, Northumberland, has received the King's Commendation for brave conduct for services when an accident occurred in a mine.

Wills

Dr. Ronald Edgar French, of Burgh Heath, Surrey, left £135,119. Dr. William George Harnett, of Hadley, Barnet, left £43,785, including £100 to the Royal Medical Benevolent Fund. Dr. Kenneth Rogers, of Bournemouth, left £12,758. Dr. James Nowell Richardson, of Halton, Leeds, left £12,064. Dr. Frank Spiller Locke, of Tunbridge Wells, Kent, formerly Reader in Physiology, King's College, London, left £232,538, with the request that, after certain bequests had been made, part of the residue go to the Royal Society, to be utilized for endowing "Locke" fellowships for research in experimental physiology and pharmacology. Sir James Purves Morisson Purves-Stewart, of London, W.8, left £57,478, including £2,500 each to the University of Edinburgh and Westminster Hospital Medical School, the income to be used in assisting senior medical students and young graduates who would benefit by temporary financial assistance.

COMING EVENTS

Annual Meeting of the British Association

The 111th annual meeting of the British Association for the Advancement of Science will be held at Newcastle-upon-Tyne from Aug. 31 to Sept. 7. Sir John Russell, F.R.S., will speak on "World Population and World Food Supplies" in his presidential address. Among the subjects to be discussed by the physiology section, of which Professor R. A. Peters is the president, are adolescent nutrition, relations of brain to mind (joint meeting with the Section of Psychology), and folic acid and anaemia.

French Congress of Electroencephalography

The Second International Congress of Electroencephalography will be held in Paris on Sept. 1–3. Information may be obtained from Dr. H. Gastaut, 149, Promenade de la Corniche, Marseilles.

French Congress of Neurology

The 4th Congress of Neurology will be held in Paris on Sept. 5–10. Information may be obtained from Dr. Raymond Garcin, 19, Rue de Bourgogne, Paris, 7e.

Photographic Exhibition

The 94th annual exhibition of the Royal Photographic Society will be held at 16, Princes Gate, London, S.W.7, from Sept. 9 to Oct. 26. The scientific, including medical, section is from Oct. 8 to Oct. 26. Particulars may be obtained from the secretary of the society at the address given above.

Physiotherapy

The Annual Congress of the Chartered Society of Physiotherapy will be held at the Assembly Hall, St. Pancras Town Hall, Euston Road, London, N.W.1, on Sept. 14–18. Particulars may be obtained from the society at Tavistock House North, Tavistock Square, London, W.C.1.

Infertility

The Family Planning Association will hold an annual conference on infertility at Edinburgh on Sept. 17–18. Particulars may be obtained from the association at 69, Eccleston Square, London, S.W.1.

Exhibition for Rheumatic Patients

The British Rheumatism Association will hold an exhibition for rheumatic patients at the Town Hall, Chelsea, on Sept. 27–30. Concurrently there will be a two-day conference on (1) the welfare of the rheumatic patient, and (2) the interests of the handicapped rheumatic. Tickets for the conference cost 10s. Information may be obtained from the Association at 5, Tite Street, Chelsea, London, S.W.3 (telephone: FLAxman 2957).

Middlesex Hospital Medical School

The annual dinner of the Middlesex Hospital Medical School will be held at the Savoy Hotel on Friday, Sept. 30, at 7 for 7.30 p.m.

SOCIETIES AND LECTURES

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, Aug. 23, 4.30 p.m., "*The Conducting System of the Heart*," by Professor Thomas Walmsley.

Friday

NATIONAL HOSPITAL: INSTITUTE OF NEUROLOGY, Queen Square, London, W.C.—Aug. 26, 5 p.m., "*Topectomy: Cortical Ablation for Treatment of Mental Illness*," by Professor J. Lawrence Pool.

APPOINTMENTS

The following have been appointed to the Civil Consulting Staff of King Edward VII Convalescent Home for Officers at Osborne, East Cowes, Isle of Wight, as from June 4: Sir Francis Fraser, M.D., F.R.C.P., Sir James Paterson Ross, K.C.V.O., M.S., F.R.C.S., W. D. W. Brooks, D.M., F.R.C.P., D. E. Bedford, M.D., F.R.C.P., D. H. Brinton, D.M., F.R.C.P., H. Osmond Clarke, C.B.E., F.R.C.S., A. E. Porritt, C.B.E, M.Ch., F.R.C.S., R. Marnham, M.Ch., F.R.C.S.

BUNTING, F. W., M.B.E., M.D., D.P.H., Medical Officer of Health for Prescot Urban District Council.

CASSON, F. R. C., M.B., B.S., D.P.M., Clinical Assistant to Department of Psychological Medicine, Charing Cross Hospital, London, W.C.

FENTON-RUSSELL, D., M.D., D.P.H., D.P.M., Consultant Psychiatrist, Stanley Royd Hospital, Wakefield, Yorkshire.

HOLLAND, C. B., M.B., Ch.B., D.A., Consultant Anaesthetist in the Ipswich Area, East Anglian Regional Hospital Board.

JONES, JOHN FRASER, M.B., B.S., House-surgeon, the Royal Hospital, Wolverhampton.

KEEPING, JOYCE AUDREY, M.D., M.R.C.P., Physician to Paddington Chest Clinic, London, W.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Crabtree.—On August 5, 1949, at the Queen Elizabeth Hospital, Birmingham, to Joyce May "Maimé" (née Airey), wife of Norman L. Crabtree, F.R.C.S., of 14, Church Road, Edgbaston, a brother for Valerie and Jennifer—John Rawcliffe.

Herford.—On August 6, 1949, at Cliveden Memorial Hospital, Bucks, to Mary (née Crago), wife of Dr M. E. M. Herford, D.S.O., a daughter.

Lambert.—On August 5, 1949, at Hillingdon Hospital, to Sadie, wife of Dr. E. Vivian Lambert, of Uxbridge, a son.

Leslie.—On July 11, 1949, at the Duke of York Nursing Home, Bradford, to Frances, wife of Dr. William Leslie, a daughter.

Murley.—On August 12, 1949, at 43, Newlands Avenue, Radlett, Herts, to Daphne (née Garrod), wife of R. S. Murley, M.S., F.R.C.S., a son—David Peter.

Ounsted.—On August 5, 1949, to Margaret Ounsted, B.M., wife of Christopher Ounsted, B.M., a son.

MARRIAGE

Eason—Towler.—On August 6, 1949, at St. Paul's Presbyterian Church, Croydon, Thomas John Eason, F.R.C.S., to *Ruth Willand Towler*, M.B., Ch.B.

DEATHS

Ashby.—On August 6, 1949, at 127, Roundhay Road, Leeds, J. E. Ashby, M.R.C.S., L.R.C.P., aged 59.

Battiscombe.—On August 4, 1949, at 29, Drakes Avenue, Exmouth, Eric George Battiscombe, M.R.C.S., L.R.C.P., aged 76.

Campbell.—On July 7, 1949, at 20, Daneswell Drive, Leasowe, Cheshire, Thomas Graham Campbell, L.R.C.P.&S.Ed., L.R.F.P.S.Glas., aged 79.

Charles.—On August 2, 1949, at Bournemouth, Rhys Pendrill Charles, T.D., M.D., of 9, Dean Park Road, Bournemouth.

Crisp.—On August 12, 1949, at 2, Hillside Road, Cheam, Surrey, Thomas Crisp, M.D., late of St. George's House, Chorley, Lancs, and Tinterfield, N.S.W.

Foster.—On August 5, 1949, at Danby, Yorks, John Robert Foster, M.B., C.M., F.R.C.S.Ed., formerly of West Hartlepool, aged 81.

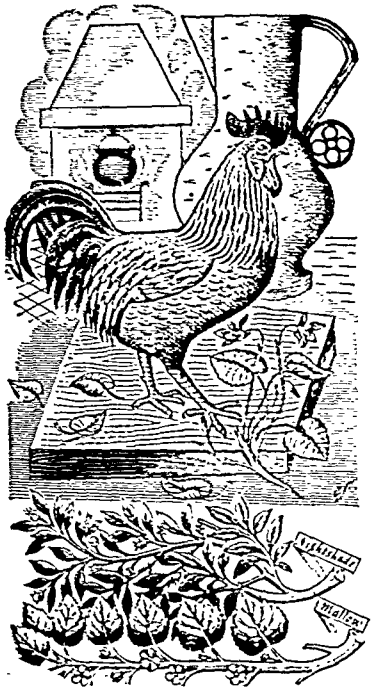
Hopkinson.—On July 31, 1949, at 6, Adams Road, Cambridge, Albert Hopkinson, M.B., B.Ch., aged 85.

Kaufmann.—On August 2, 1949, Walter Kaufmann, M.D., of 18, Danes Court, Wembley Park, Middlesex.

Macneill.—On August 6, 1949, at 64, Hook Road, Surbiton, Surrey, Robert Archibald Macneill, M.B., Ch.B., aged 74.

McNabb.—*On July 28, 1949, Harry Horsman McNabb, M.D., of 8a, St. John Street, Manchester, and Butley Close, Prestbury, Cheshire, aged 74.*

May.—On August 3, 1949, at Torquay, Harry John May, L.S.A., of Chudleigh, Devon, aged 84.



Mitchell.—On July 29, 1949, at the Royal Hospital, Wolverhampton, Nevil Robert Kennedy Mitchell, F.R.C.S.Ed.

Newton.—On August 3, 1949, in Melbourne, Australia, Sir Alan Newton, M.S., F.R.C.S., aged 62.

Palmer.—On July 28, 1949, at Accra, Gold Coast, Ralph Winnall Palmer, M.R.C.S., L.R.C.P., aged 35.

Parkhurst.—On July 27, 1949, at Rathan, Lewes Road, Newhaven, Sussex, Rodie Parkhurst M.B., C.M.Ed., aged 80.

Wilson.—On July 30, 1949, at 76, Farquhar Road, Edgbaston, Birmingham, *Theodore Stacey Wilson*, M.D., F.R.C.P., aged 88.

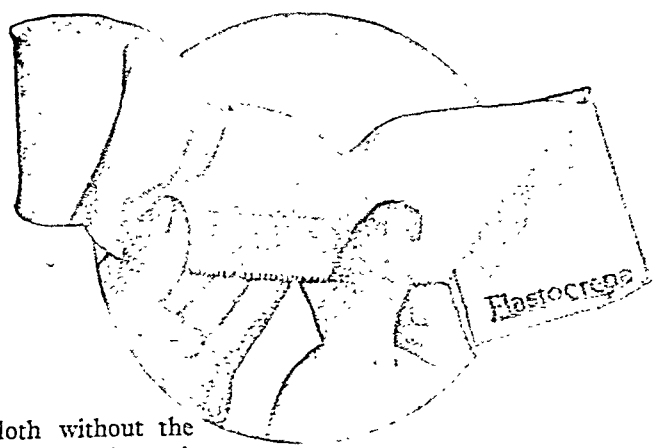
IN ANALGESIA

1540: *"Take a fatte piece of veale or ellse a fatte capon and boyle it in water or ellse white wyne and strayne it from the fleshe, and sett the saide lycor over the fyre agayn, and putt therto these things folowing, of mallowes ii. unces, of violett leaves, of night shade ana ℥ i. lett them boyle untyll they be very softe and tendre, and powre awaye the licor from them, and putt therto barley water as shall suffise to make it a pulthes".*

(A pulthes to cease payne devised by DR. BUTTS)

Today the physician has, in 'Physeptone,' a specific agent for the relief of pain. 'Physeptone' is more powerful than morphine and does not cause hypnosis or constipation. It may with advantage replace morphine as an analgesic for patients confined to bed. 'Physeptone' is available as 5 mgm. compressed products for oral administration (bottles of 25, 100 and 500), and as injection, 10 mgm. per c.c. (ampoules of 1 c.c., in boxes of 12).

'PHYSEPTONE'



dl-2-DIMETHYLAMINO-4:4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

THE ESTABLISHED ANALGESIC

BURROUGHS WELLCOME & CO. (THE WELLCOME FOUNDATION LTD.) LONDON

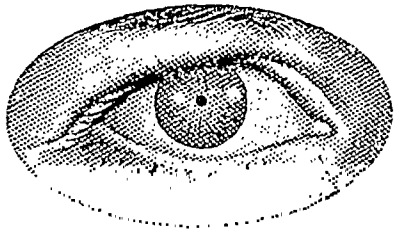
Valuable for

COMPRESSION and SUPPORT

Elastocrepe is Elastoplast cloth without the adhesive spread. It, therefore, has the unique properties of *stretch* and *regain* which are associated with Elastoplast.

Elastocrepe provides comfortable and adequate support and compression for its particular purpose, and is superior in every way to the ordinary crepe bandage. When soiled it may be washed—washing *renews* its elasticity.

Elastocrepe TRADE MARK



SMOOTH SURFACE CREPE BANDAGE

DFP

DI-ISOPROPYL FLUOROPHOSPHONATE

For the treatment of Glaucoma, Paralytic Ileus and Myasthenia Gravis

A potent miotic and inhibitor of cholinesterase

D.F.P. resembles physostigmine in promoting the accumulation of acetyl choline in the tissues. But the inhibition of cholinesterase by D.F.P. is irreversible and occurs at a much lower concentration. Clinical trials show that D.F.P. gives prolonged control of intraocular tension in glaucoma, and is often effective when other miotics fail. D.F.P. also increases the motility of both large and small intestines in paralytic ileus and may reduce the requirement of neostigmine in myasthenia gravis.

Available as:

D.F.P. EYE-DROPS-BOOTS. 0.1% solution in arachis oil. Bottles of 10 ml.

INJECTION OF D.F.P.-BOOTS. Sterile 0.1% solution in arachis oil. Box of 6 x 2 ml. ampoules.

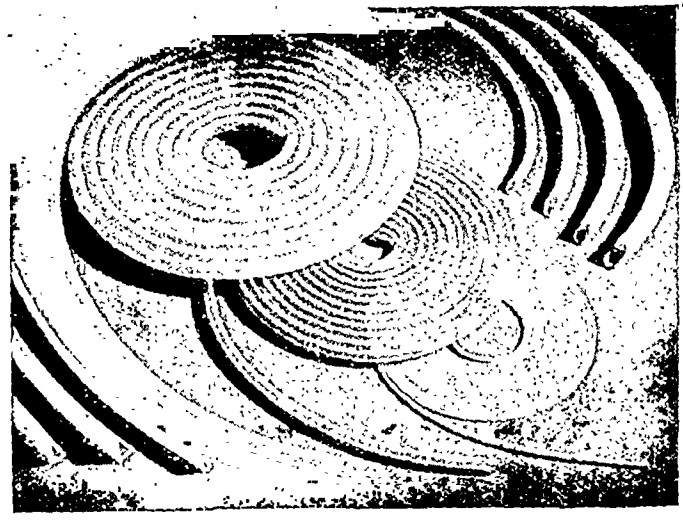
Here's metal more attractive

HAMLET, ACT III, SCENE II

IRON in readily assimilable form is the metal so vital for the successful treatment of hypochromic anæmias.

Of the iron compounds usually given by mouth, ferrous sulphate is generally recognised as the most effective.

In 'PLASTULES,' ferrous sulphate is presented in its most attractive form—as a semi-fluid in a capsule which rapidly dissolves in the stomach, thus ensuring maximum absorption. 'PLASTULES' induce a rapid response without gastric upset.



Each 'Plastule' Plain contains Ferrous Sulph. Exsicc. B.P. 5 gr., dried yeast ¾ gr. They are also available with Hog Stomach, with Liver Extract, and with Folic Acid.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Infection from Ducks' Eggs

Q.—*What is the toxin sometimes present in ducks' eggs? Is there less danger of infection if the duck is kept in a pen and given fresh water daily, with no access to dirty water? What precautions should be taken in cooking ducks' eggs?*

A.—The retention of the term "food-poisoning" to describe a variety of conditions, some due to toxins, some to infection by living bacteria, evidently explains the misconception in this question. The noxious agent present in a small proportion of ducks' eggs is not a toxin but a living organism, usually *Salmonella typhi-murium* ("*B. aertrycke*"), sometimes *Salm. enteritidis* ("Gaertner's bacillus"). These organisms cause an infection in the bird itself and are actually within the egg when it is laid. They are closely related to the enteric group but produce a very different type of disease, with a short incubation period (one to two days) and an acute onset. The condition takes the form of an acute catarrh of the entire alimentary tract, with fever and diarrhoea, and its duration is commonly only three days. Birds free from the infection will not acquire it if kept under clean conditions, and particularly away from ponds and other dirty water. Possible sources of infection, apart from other birds, are pigs and rodents. No form of cooking which fails to coagulate the whole of the egg protein is likely to destroy the organism—that is to say that eggs lightly boiled or poached will be infective; they should be safe when boiled hard or when used in cake-making.

Bleeding Nipples

Q.—*What is the cause of exudation of blood from both nipples of a nursing mother? In the case I have in mind—in a primipara aged 32—bleeding started immediately after parturition, and for a week blood mixed with colostrum could be expressed from the nipples.*

A.—This phenomenon is well known but is comparatively rare. It is associated with the enormously increased blood supply and congestion of the breasts which develop very quickly after childbirth, and is presumably the result of some inherent fragility of the capillaries around the alveoli. It has nothing to do with the character of the labour. Sometimes the blood is not fully mixed with the colostrum or milk—suggesting that the trouble is limited to certain ducts and alveoli. In other cases it is intimately mixed, giving the appearance of "brown" milk. The occurrence may be only transitory, subsiding gradually after the first few days, but sometimes it persists long enough to justify discontinuing breast-feeding. Although the writer has no experience of it, it would seem worth while trying the effect of 5 mg. stilboestrol twice daily for 24 to 48 hours, during which time suckling or expression of the milk should be continued to avoid suppression of lactation.

Persistent Sinus after Fractured Coccyx

Q.—*A woman of 28 had a fall 10 years ago resulting in fracture of the coccyx. A loose piece of bone was removed, but the wound healed slowly and a shallow sinus formed. Several sequestra have since been removed, but the sinus persists with a slight clear discharge. The chest is clear. For the past few years the sinus has periodically shown a tendency to close, and this is accompanied by photophobia, headache, and irritability. These symptoms do not appear to be neurotic. What treatment do you advise?*

A.—From the history it appears that there was infection of the fracture haematoma, leading to osteitis of the coccyx. Persistence of the sinus suggests either that infection is still active in the remaining bone or that there is a further sequestrum. In general, the treatment of such cases would depend on the clinical course and the radiographic appearances. If evidence of residual bone infection were found on x-ray examination, excision of the coccyx would be indicated. If the radiographs were inconclusive, a decision would have to be made on clinical grounds alone; but, unless the clinical course suggested that continued progress was being made towards final spontaneous closure, excision of the coccyx—preferably under penicillin and sulphonamide control—would usually be advisable. Local and general symptoms after temporary closing of a sinus—particularly when accompanied by pyrexia—often indicate local pocketing of pus. In the absence of pocketing it is difficult to understand how such symptoms as are described in this case could arise.

Sleepwalking in Childhood

Q.—*A boy of 7 walks in his sleep. Is he likely to come to any harm if he should wake to find himself out of bed? Should one talk to him, or should one attempt to lead him back to bed—or merely follow and allow him to return in his own time? He will be moving shortly to a house at the seaside. Would he be likely to walk out of the house to the beach, which is only a short distance away? What do you advise?*

A.—It is generally agreed that, although sleepwalkers seldom come to harm, this does sometimes happen. In childhood somnambulism is not uncommon, the child often acting out a dream in which he is looking for his mother to comfort him. The stimulus may be anything emotionally upsetting, such as worry over school or home relationships; if this can be detected and resolved, sleepwalking usually ceases unless there is a general disturbance of personality involving great anxiety. It is better to let a child find his way back to bed, if possible, giving him a tucking-up that even in a dazed state he may find reassuring. It is advisable to avoid over-excitement and alarming reading at bedtime, which should be made a specially pleasant time so that he goes off to sleep feeling happy and safe. Phenobarbitone can also be a useful preventive. It is just possible that the boy, if he knows of the forthcoming move to the sea, may be disturbed by fantasies about the change of house, and will settle down when this has actually taken place.

Fat Legs

Q.—*An otherwise attractive spinster of 25 is socially handicapped by "over-sturdy legs." The distribution of fat is normal above the waist but massive below; periods are scanty, and there is some hypothyroidism. Can you explain the localization of fat to this site, and suggest a remedy?*

A.—Fat distribution below the waist, with absence of fat above the waist, is characteristic of the disorder known as lipodystrophy, and the cause is unknown. However, in idiopathic adiposity it is by no means uncommon for this distribution to be present in milder degree, or for the fat to be located in the abdomen and hips, and perhaps the upper arms, leaving the face thin. In Cushing's syndrome the face and neck, in contrast, are fat. No one has yet been able to explain the cause of the many varieties of fat distribution met with. The treatment is that of adiposity in general, and unfortunately the fat depots are sometimes more resistant than the areas where fat is normal. As regards "over-sturdy" legs, this has a constitutional genetic basis, and is probably not of endocrine origin. It is certainly not amenable to endocrine therapy.

Thrombo-angiitis Obliterans

Q.—*How should one treat thrombo-angiitis obliterans in a man of 50 years who has been suffering from intermittent claudication in both legs for two years? Is vitamin E of any value?*

A.—It is not easy to prescribe suitable treatment when so few details are given. The fundamental indications are to improve the collateral circulation and to minimize the risks of gangrene by scrupulous attention to the toilet of the feet. The various methods of improving the circulation include the use of

vasodilator drugs, saline and ether–saline injections, intermittent venous occlusion, and lumbar sympathectomy. Specific indications for these various measures can be found in the standard textbooks. Vitamin E and similar substances, especially α-tocopherol, have recently been employed in the treatment of peripheral vascular disease; early reports were enthusiastic, but these have not been endorsed by subsequent experience.

Enlarged Liver after Amoebic Dysentery

Q.—*A European living in an area where amoebiasis is endemic, and who has had amoebic dysentery in the past, suffers from a painful enlarged liver with moderate pyrexia. No protozoa have been found in the stools, and malaria was excluded. The total leucocyte count did not rise above 7,400 per c.mm., and no jaundice was present. By the time anti-amoebic treatment was started (after eight days) the temperature had settled. Pain and liver enlargement persisted through a full course of emetine injections, though diminishing in severity. The patient is now free from signs and symptoms. Is amoebiasis the probable diagnosis? According to the text-books, leucocytosis and a rapid response to emetine are characteristic of amoebic hepatitis. Is liver biopsy simple and safe? Could you refer me to a description of the technique?*

A.—The problem of hepatic enlargement after amoebic dysentery is a difficult one. There is a group of patients in whom the textbook criteria of amoebic hepatitis exist and who rapidly recover after injections of emetine. There is another group with which medical officers serving in the Middle East and Italy during the war became familiar. In these patients there is complaint of pain in the right hypochondrium and the liver is moderately enlarged and tender; there is no improvement with injection of emetine, and biopsy usually shows the liver tissue to be normal. Symptoms disappear over a period of weeks or months without specific treatment. The nature of this syndrome, and, indeed, whether it is related to amoebiasis, are uncertain. Liver biopsy is simple and safe, but inadvisable if active amoebic hepatitis is suspected. A description of the technique appeared in this *Journal* recently (1949, **1**, 657).

Aspirin and Haematemesis

Q.—*Is there a real risk of haematemesis following the continued administration of aspirin? Can you give references to the literature on this subject?*

A.—The danger of haematemesis following the taking of aspirin is not related so much to the continued use of the drug as to individual susceptibility. In certain persons aspirin produces inflammatory reaction when it comes in contact with the mucosa of the lesser curvature of the stomach. Aspirin in solution has been shown by Douthwaite and Lintott (*Lancet*, 1938, **2**, 1222) to be non-irritant. The difficulty experienced hitherto has been that calcium aspirin has tended to break down with the liberation of salicylic acid. A preparation is now sold which overcomes this disadvantage.

Angioneurotic Oedema

Q.—*What are the prognosis and treatment of angioneurotic oedema in a man aged 68? He is allergic to strawberries and other foods, and at the age of 36 he had severe pruritus which cleared up under x-ray treatment. He now seems to be in constant fear of "choking." Is there anything better than adrenaline, which appears to have been effective in previous attacks? Would desensitization be worth while?*

A.—Since adrenaline was effective in previous attacks, this patient might be supplied with a syringe and adrenaline; he could then give himself an injection as soon as an attack started. "Neo-epinine" ("aleudrine") could be used instead of adrenaline, and one of the antihistaminic drugs, such as "phenergan" ("3277 R.P."), "anthisan" (pyranisamine maleate), or "benadryl," could also be given. The most careful history should be taken for possible food or drug allergens, and a food diary might help. Unusual foods, and foods taken in excess at times corresponding to the attacks, as well as the occasional headache powder, hypnotic, or purgative, should be especially inquired for. Skin testing is rarely if ever of value in this condition. Trial eliminative measures must include not only the suspected food as usually eaten, but all foods which contain any trace of the suspected allergen. Specific and non-specific desensitization are of doubtful value. A thorough search should be made for a focus of infection. The prognosis depends very largely on finding the cause, which is often difficult and frequently unsuccessful.

NOTES AND COMMENTS

Muscae Volitantes.—RANA IN FAUCIBUS and RENIS FLUITANS (Mr. Frederick Ridley, amanuensis) write: We write on behalf of our sisters the Muscae Volitantes, who are much distressed by the article so headed in "Any Questions?" (July 23, p. 241). Ever since God in His wisdom caused light to pass through a living jelly so that beauty might illumine the soul of man these charming and entertaining translucent threads, whorls, and dots have cast their shadows upon the retinal image. Normally mankind has ignored them; often, under favourable conditions of lighting, he has been delighted by their antics. They have excited the poet's fancy and helped to while away many an idle hour. Loved by most, they have always been an annoyance to microscopists and, we admit with some regret, they have from the earliest times provided a focus of anxiety for humans of sick mind. Our sisters have consoled themselves with the thought that many people have chosen less pleasant natural phenomena on which to focus their mental illness. To us, of course, it is no new thing for humans to seek to "cure" natural phenomena and to "invent" disease (first they imagine a pathology and from that, with much word-spinning, is deduced a logical treatment—preferably an operation), but for our sisters this is a new experience. Maybe magic is as young, as we know it to be as old, as man. So uvulae have been amputated, the frenulum linguae cut, kidneys "fixed," nipple strings "broken," and now muscae volitantes are to be treated both medically and, God help us, surgically. It may be argued that disease processes can give rise to optical phenomena simulating our sisters' appearance, but we doubt it. In such cases gross, ugly, opaque monsters may be seen, but surely these could hardly be confused with our delicate sisters. Moreover, the normal person recognizes at once that such appearances are new—muscae he has had with him always. We beg you to publish our letter: first, because it is both inaccurate and unwise to use the same name for the effects of disease processes as is used by Everyman to describe a perfectly normal experience; secondly because, as we have said, many humans of sick mind are already worried by our sisters, and these people should be comforted, not alarmed and confused; and, lastly, because we are quite sure that the right attitude towards our sisters, apart from affection or indifference, is that of *Punch*, who calls them "flying mice," and of the late Harrison Butler, who wisely said, "Muscae Volitantes are things we can all see but only the damn fools look at 'em."

Family Planning.—The Family Planning Association state that they are often asked by members of the public for the names and addresses of medical practitioners who give advice on family planning. Medical men who wish to undertake this work or to obtain information about it are invited to write to the Family Planning Association at 64, Sloane Street, London, S.W.1.

Disturbed Micturition in Disseminated Sclerosis.—Dr. E. LEDERGERBER (St. Gallen, Switzerland) writes: The answer given to the question under this heading ("Any Questions?" May 7, p. 832) is not very hopeful. I have had fair success in such cases with a testicular extract containing the hydrosoluble and liposoluble principles (not the artificial product) in women and oestrone in men.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology, Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcent, London.*

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London.*

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY AUGUST 20 1949

British Medical Association

COUNCIL AND COMMITTEES FOR 1949-50

COUNCIL

EX OFFICIO

Dr. C. W. C. Bain, Harrogate, *President.*
Dr. E. A. Gregg, London, *Chairman of Council.*
Mr. A. M. A. Moore, London, *Treasurer.*
Dr. J. A. Brown, Birmingham, *Acting Chairman of Representative Body.*
Professor T. P. McMurray, Liverpool, *President-Elect.*
Sir Lionel Whitby, Cambridge, *Immediate Past-President.*
Dr. H. Guy Dain, Birmingham, *Immediate Past-Chairman of Council.*
Mr. R. L. Newell, Cheadle, Cheshire, *Chairman, Central Consultants and Specialists Committee.*
Dr. S. Wand, Birmingham, *Chairman, General Medical Services Committee.*

TWENTY-TWO ELECTED BY GROUPED BRANCHES IN GREAT BRITAIN AND NORTHERN IRELAND

England and Wales:

Dr. J. Cottrell, Grimsby.
Dr. S. F. L. Dahne, Reading.
Dr. D. B. Evans, Coedpoeth, near Wrexham.
Dr. H. M. Golding, Bristol.
Dr. F. Gray, London.
Dr. R. Hale-White, London.
The Rt. Hon. Lord Horder, London.
Dr. I. G. Innes, Hull.
Dr. R. P. Liston, Tunbridge Wells.
Mr. Percy Malpas, Liverpool.
Mr. D. R. Owen, Chester.
Dr. J. C. Pearce, Diss, Norfolk.
Dr. J. A. Pridham, Weymouth.
Mr. Eric Steeler, London.
Mr. J. W. Tudor Thomas, Cardiff.
Dr. N. E. Waterfield, Little Bookham, Surrey.
Mr. Weldon Watts, Newcastle-upon-Tyne.

Scotland:

Dr. Mary Esslemont, Aberdeen.
Dr. J. G. M. Hamilton, Edinburgh.
Dr. W. Jope, High Blantyre, Lanarkshire.
Dr. W. M. Knox, Glasgow.

Northern Ireland:

Dr. N. S. Dickson, Templepatrick, Co. Antrim.

SEVEN ELECTED BY BRANCHES OUTSIDE GREAT BRITAIN AND NORTHERN IRELAND

Dr. J. H. Anderson, Ruthin, N. Wales.
Professor J. S. English, Newtownards, Co. Down.
Dr. P. T. O'Farrell, Dublin.
Dr. P. C. C. Garnham, Slough, Bucks.
Dr. Isaac Jones, London.
Dr. H. B. Morgan, London.
Mr. J. A. Stallworthy, Oxford.

TWELVE ELECTED BY GROUPED REPRESENTATIVES

Mr. A. Lawrence Abel, London.
Dr. Alexander Brown, Linton, Cambs.
Mr. L. Dougal Callander, Doncaster.
Mr. Ian J. Fraser, Belfast.
Dr. H. R. Frederick, Port Talbot, Glam.
Dr. P. J. Gibbons, Liverpool.
Dr R. G. Gordon, Bath.
Dr. D. F. Hutchinson, London.
Dr. G. W. Ireland, Ford, Midlothian.
Dr. G. MacFeat, Douglas, Lanarkshire.
Dr. T. W. Morgan, New Malden, Surrey.
Mr. D. S. Pracy, Atherstone, Warwicks.

EIGHT ELECTED BY REPRESENTATIVE BODY

Dr. J. C. Arthur, Low Fell, Co. Durham.
Dr. O. C. Carter, Bournemouth.
Dr. James Fenton, London.
Dr. R. Forbes, London.
Dr. J. A. Gorsky, London.
Dr. Ian D. Grant, Glasgow.
Dr. J. A. L. Vaughan Jones, Leeds.
Dr. S. Wand, Birmingham.

TWO ELECTED BY PUBLIC HEALTH SERVICE MEMBERS

Dr. C. Metcalfe Brown, Manchester.
Dr. R. H. H. Jolly, Wolverhampton.

THREE ELECTED BY REPRESENTATIVE BODY TO REPRESENT THE SERVICES

Surgeon Rear-Admiral C. H. M. Gimlette, Epsom, Surrey (R.N.M.S.).
Major-General Sir Percy Tomlinson, Purley, Surrey (A.M.S.).
Air Commodore J. Kyle, Wendover, Bucks (R.A.F.M.S.).

ONE ELECTED BY WOMEN MEMBERS

Dr. Janet K. Aitken, London.

COMMITTEES

I. STANDING COMMITTEES

(NOTE.—The President, Chairman of Representative Body, Chairman of Council, and Treasurer are members, *ex officio*, of all Standing Committees.)

ARMED FORCES COMMITTEE

Surgeon Rear-Admiral C. H. M. Gimlette, Epsom, Surrey.
Air Commodore James Kyle, Wendover, Bucks.
Colonel E. C. Linton, London.
Dr J. E. Rusby, Leeds.
Mr. Eric Steeler, London.
Major-General Sir Percy S. Tomlinson, Purley, Surrey.
Dr. Angus Weston, Greenford, Middlesex.
One Representative from each of the following: Royal Naval Medical Service, Royal Army Medical Corps, Royal Air Force Medical Service, Royal Naval Volunteer Reserve, Royal Army Medical Corps (Territorial Army), Royal Air Force (Volunteer Reserve).

CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

Members Appointed by Representative Body:

England and Wales: Mr. A. Lawrence Abel, London; Mr. A. Dickson Wright, London.
Scotland: Dr. Alexander Smith, Stonehouse, Lanarks.
Northern Ireland: Vacancy.

Members Appointed by Council:

Mr. A. Staveley Gough, Watford, Herts.
Mr. R. L. Newell, Cheadle, Cheshire.

Members Appointed by Regional Consultants and Specialists Committees:

Mr. Roy Banham, Northampton.
Dr. W. A. Bourne, Hove.
Mr. G. H. Buckley, Blackpool.
Professor P. C. P. Cloake, Birmingham.
Dr. Beryl D. Corner, Bristol.
Dr. A. A. Cunningham, Kingston-on-Thames, Surrey.
Mr. E. R. Frizelle, Leicester.
Mr. W. H. George, Birmingham.
Mr. H. L. Hardy Greer, Belfast.
Professor S. J. Hartfall, Leeds.
Dr. T Rowland Hill, London.
Dr. A. W Holgate, Chester.
Dr. R. D. Lawrence, London.
Dr. R. G. McInnes, Oxford.

Mr. O. E. J. McOustra, Cheltenham.
Mr. P. Malpas, Liverpool.
Dr. Robert Marshall, Belfast.
Dr. J. Murray, Iver Heath, Bucks.
Dr. A. A. McI. Nicol, Sunderland.
Dr. R. A. Noble, Cambridge.
Mr. W. C. Northfield, London.
Dr. A. G. Ogilvie, Newcastle-upon-Tyne.
Professor T. H. Oliver, Manchester.
Dr. W. Esmond Rees, Swansea.
Mr. T. Holmes Sellors, London.
Mr. N. Ross Smith, Bournemouth.
Professor G. I. Strachan, Cardiff.
Mr. H. Taylor-Young, Salisbury.
Mr. J. M. Ridley Thomas, Norwich.
Dr. E. C. Warner, London.
Mr. Donald Watson, Bradford.
Dr. J. Wilkie, Sheffield.

Members Appointed by the Consultants and Specialists Subcommittee of Scottish Committee:

Dr. J. D. S. Cameron, Edinburgh.
Professor L. J. Davis, Glasgow.
Dr. I. D. Easton, Perth.
Mr. I. Simson Hall, Edinburgh.
Dr. J. G. M. Hamilton, Edinburgh.
Mr. N. J. Logie, Aberdeen.
Mr. W. S. Mack, Glasgow.
Mr. T. Murray Newton, Glasgow.
Dr. A. R. Wilson, Inverness.
Dr. J. H. Wright, Glasgow.

Co-opted Members:

Dr. N. J. England, Oxford.
Mr. C. E. Kindersley, Bath.

Together with five part-time consultants and specialists; two members appointed by the General Medical Services Committee; one member appointed by each of the following committees: Occupational Health, Public Health, and Private Practice; and one member by each of the following Group Committees: Anaesthetists, Consulting Pathologists, Dermatologists, Non-Professorial, Ophthalmic, Orthopaedic, Otolaryngologists, Physical Medicine, Psychological Medicine, Radiologists, Spa Practitioners, Tuberculosis and Diseases of the Chest, and Venereologists.

CENTRAL ETHICAL COMMITTEE

Dr. E. C. Dawson, Derby.
Dr. R. Forbes, London.
Dr. H. R. Frederick, Port Talbot, Glam.
Dr. J. F. Lambie, Glasgow.
Dr. T. W. Morgan, New Malden, Surrey.
Dr. H. W. Pooler, Ashover, near Chesterfield.
Dr. S. Noy Scott, Plympton, Plymouth.
Dr. C. M. Stevenson, Cambridge.
Dr. J. G. Thwaites, Brighton.
Dr. N. E. Waterfield, Little Bookham, Surrey.
Dr. F. B. Winfield, Birmingham.
Dr. W. Woolley, Bristol.

CHARITIES COMMITTEE

Dr. Janet K. Aitken, London.
Dr. L. W. Jones, Llanfairpwll, Anglesey.
Dr. J. W. McCarthy, Hendon.
Dr. H. W. Pooler, Ashover, near Chesterfield.
Dr. H. Robinson, Tunbridge Wells.
Dr. N. B. Stewart, Edinburgh.
Dr. N. E. Waterfield, Little Bookham (Representative of Association on Council of Epsom College).
Mr. A. Dickson Wright (Representative of Association on Committee of Management of the Royal Medical Benevolent Fund).

COLONIES AND DEPENDENCIES COMMITTEE

Dr. J. H. Anderson, Ruthin, N. Wales.
Professor J. S. English, Newtownards, Co. Down.
Dr. P. C. C. Garnham, Slough, Bucks.
Mr. J. L. Gilks, Petersfield, Hants.
Dr. I. G. Innes, Hull.
Dr. Isaac Jones, London.
Sir Hugh Lett, Walmer, Kent.
Mr. C. F. Mayne, Devonport.
Dr. H. B. Morgan, London.
Dr. P. T. O'Farrell, Dublin.
Dr. J. B. Wrathall Rowe, Wealdstone, Middlesex.
Mr. J. A. Stallworthy, Oxford.

FINANCE COMMITTEE

The Chairman of the following Committees: Organization, Journal, Science, Private Practice, Central Ethical, General Medical Services, and Building.
Dr. H. Guy Dain, Birmingham.
Dr. T. Gardner, Featherstone, near Pontefract.
Dr. J. O. McDonagh, Stanley, Perth.
Mr. C. F. Mayne, Stoke, Devonport.

GENERAL MEDICAL SERVICES COMMITTEE

Dr. W. Jope, Blantyre, Lanarks (Chairman of Conference of Local Medical Committees).

Six Elected by Representative Body:

Dr. H. Guy Dain, Birmingham
Dr. H. H. Goodman, Newcastle-upon-Tyne.
Dr. F. Gray, London.
Dr. W. Knox, Glasgow.
Dr. S. Wand, Birmingham.
One vacancy.

With twenty-seven Direct Representatives of Local Medical Committees in Great Britain and Northern Ireland. Six to be elected by the Annual Conference of Representatives of Local Medical Committees, two nominated by the Central Consultants and Specialists Committee, one nominated by the Medical Women's Federation, one nominated by the Society of Medical Officers of Health, with power to co-opt.

JOURNAL COMMITTEE

Dr. O. C. Carter, Bournemouth.
Dr. Mary Esslemont, Aberdeen.
Dr. R. G. Gordon, Bath.
Dr. R. P. St. L. Liston, Tunbridge Wells.
Dr. Mona Macnaughton, Newcastle-upon-Tyne.
Dr. J. C. Matthews, Downton, Wilts.
Dr. S. Noy Scott, Plymstock, Plymouth.
Dr. R. W. L. Ward, Doncaster.
Chairman of the Central Ethical Committee.
One member appointed by the Organization Committee.
One member appointed by the Science Committee.

OCCUPATIONAL HEALTH COMMITTEE

Dr. H. Alexander, London.
Dr. L. Dougal Callander, Doncaster.
Dr. J. Cotterell, Grimsby.
Dr. J. A. L. Vaughan Jones, Leeds.
Professor R. E. Lane, Manchester.
Dr. R. H. D. Laverty, Coventry.
Dr. J. B. Wrathall Rowe, Wealdstone, Middlesex.
Dr. Donald Stewart, Birmingham.
One member appointed by the following Committees: Private Practice, Central Consultants and Specialists, General Medical Services, Public Health, and Dermatologists Group.
Three members nominated by the Association of Certifying Factory Surgeons.
Four members nominated by the Association of Industrial Medical Officers.
With power to co-opt.

ORGANIZATION COMMITTEE

Dr. H. R. Frederick, Port Talbot, Glam.
Dr. F. Gray, London.
Dr. Kate Harrower, Glasgow.
Dr. I. G. Innes, Hull.
Dr. J. H. E. Moore, Leeds.
Dr. J. A. Pridham, Weymouth.
Dr. F. M. Rose, Preston.
Dr. D. A. Saklatvala, West Bromwich.
One member appointed by the Colonies and Dependencies Committee.

PRIVATE PRACTICE COMMITTEE

Dr. O. C. Carter, Bournemouth.
Dr. Robert Forbes, London.
Dr. H. M. Golding, Bristol.
Dr. E. W. Goodwin, Leicester.
Dr. J. A. Gorsky, London.
Dr. I. D. Grant, Pollokshields, Glasgow.
Dr. J. A. Ireland, Shrewsbury.
Dr. D. L. S. Johnston, Halifax.
Dr. D. T. McDonald, Belford, Northumberland.
Dr. Mona Macnaughton, Newcastle-upon-Tyne.
Dr. T. W. Morgan, New Malden, Surrey.
Dr. H. Barbara Woodhouse, Stanmore, Middlesex.
One member to be appointed by each of the following Committees: Central Consultants and Specialists, Public Health, and General Medical Services.
With power to co-opt.

PUBLIC HEALTH COMMITTEE

Dr. G. F. Buchan, London.
Dr. R. Gordon Cooke, Derby.
Dr. H. Guy Dain, Birmingham.
Dr. Mary Esslemont, Aberdeen.
Dr. James Fenton, London.
Dr. J. M. Gibson, Huddersfield.
Dr. J. A. Ireland, Shrewsbury.
Dr. J. B. [illegible]. Lanarks.
Dr. J. Rid[illegible]
Dr. J. A. [illegible]

Two Members of Council Elected by Public Health Service Members:
Dr. C. Metcalfe Brown, Manchester.
Dr. R. H. H. Jolly, Wolverhampton.

Two members to be nominated by the Society of Medical Officers of Health.
One member to be appointed by the Private Practice Committee.
One member to be appointed by the Central Consultants and Specialists Committee.
With power to co-opt three additional members.

SCIENCE COMMITTEE

Mr. A. Lawrence Abel, London.
Dr. Janet K. Aitken, London.
Mr. Hugh Carson, Birmingham.
Mr. V. Zachary Cope, London.
Dr. R. G. Gordon, Bath.
Sir Hugh Lett, Walmer, Kent.
Dr. R. P. Liston, Tunbridge Wells.
Dr. J. C. Macarthur, Carluke, Lanarks.
Dr. J. C. Matthews, Downton, Wilts.
Professor R. J. Willan, London.
One member appointed by Journal Committee.

SCOTTISH COMMITTEE

Members of Council:
Dr. Mary Esslemont, Aberdeen.
Dr. I. D. Grant, Glasgow.
Dr. J. G. M. Hamilton, Edinburgh.
Dr. G. W. Ireland, Pathhead.
Dr. W. Jope, High Blantyre.
Dr. W. M. Knox, Glasgow.
Dr. George MacFeat, Douglas.

Members Elected by Divisions in Scotland:
Dr. J. C. Adam, Forres.
Dr. F. E. Anderson, Stranraer.
Dr. J. R. Anderson, Fortrose.
Dr. J. T. Baldwin, Penicuik.
Dr. A. Climie, Barrhead.
Dr. W. Leslie Cuthbert, Stirling.
Dr. William Gibson, Old Kilpatrick.
Dr. I. D. Grant, Glasgow.
Dr. W. Nicol Gray, Helmsdale.
Dr. Kate Harrower, Glasgow.
Dr. J. M. Johnstone, Leven.
Dr. James Kelman, Perth.
Dr. J. F. Lambie, Glasgow.
Dr. D. Dale Logan, Newmains.
Dr. K. McLay, Galashiels.
Dr. I. M. MacLeod, Inverness.
Dr. A. F. Wilkie Millar, Edinburgh.
Dr. D. Myles, Forfar.
Dr. R. Richards, Aberdeen.
Dr. D. S. Robertson, Edinburgh.
Dr. R. A. B. Rorie, Dundee.
Dr. A. Scott, Ayr.
Dr. J. G. B. Shand, Cults
Dr. J. Watson, Dumfries.

Together with three representatives of Scottish Royal Medical Corporations.
With power to co-opt not more than three members.

WELSH COMMITTEE

Members of Council Representing Branches in Wales and Monmouthshire:
Dr. D. B. Evans, Coedpoeth, near Wrexham.
Dr. H. R. Frederick, Port Talbot, Glam.
Mr. J. W. Tudor Thomas, Cardiff.

Secretaries of the North Wales and South Wales and Monmouthshire Branches:
Mr. O. Vaughan Jones, Bangor, N. Wales.
Dr. W. V. Howells, Swansea.

Representatives in Representative Body of Constituencies in Wales, Monmouthshire, and Shropshire:
Dr. T. R. Bryant, Tredegar, Mon.
Mr. C. J. Cellan-Jones, Swansea.
Dr. J. F. Clarke, Newtown, Mont.
Dr. T. W. Davies, Swansea.
Mr. J. B. Dobson, Mold, Flints.
Mr. J. T. Rice Edwards, Newport, Mon.
Dr. G. E. Harries, Cardiff.
Dr. W. V. Howells, Swansea.
Dr. D. M. Hughes, St. Clears, Carmarthen.
Dr. A. Maddock Jones, Llandudno.
Dr. J. Griffith Jones, Rhondda, Glam.
Dr. H. C. C. Joyce, Rhiwbina, near Cardiff.
Dr. E. O. Lakey, Rhyl, N. Wales.
Dr. J. O. McCarter, Whitchurch, Salop.
Dr. H. F. Moffit, Aberdare.
Dr. D. G. Morgan, Penarth.
Mr. J. W. Tudor Thomas, Cardiff.
Dr. G. P. Williams, Holyhead, Anglesey.
Dr. M. G. Williams, Cardiff.
Dr. Oscar Williams, Llanelly.

II. GROUP COMMITTEES

(NOTE.—One-third of the members of the Group Committees will retire annually by rotation.)

ANAESTHETISTS GROUP COMMITTEE

Dr. Freda B. Bannister, Iron Bridge, Shropshire.
Dr. J. A. Elliott, Belfast.
Dr. Frankis Evans, London.
Dr. H. W. Featherstone, Burton-on-Trent.
Dr. T. Cecil Gray, Liverpool.
Dr. W. Alexander Low, London.
Dr. Z. Mennell, Petworth.
Dr. W. W. Mushin, Cardiff.
Dr. G. Organe, London.
Dr. H. H. Pinkerton, Glasgow.
Dr. S. Rowbotham, London.
One Representative of the Section of Anaesthetics of the Royal Society of Medicine.

DERMATOLOGISTS GROUP COMMITTEE

Dr. G. W. Bamber, Liverpool.
Dr. R. T. Brain, London.
Dr. L. Forman, London.
Dr. F. F. Hellier, Leeds.
Dr. I. H. McCaw, Belfast.
Dr. R. M. B. Mackenna, London.
Dr. J. Ferguson Smith, Glasgow.
Dr. H. J. Wallace, London.
Dr. C. H. Whittle, Cambridge.
Dr. J. E. M. Wigley, London.

FULL-TIME NON-PROFESSORIAL MEDICAL TEACHERS LABORATORY AND RESEARCH WORKERS GROUP COMMITTEE

Dr. Georgiana M. Bonser, Leeds.
Mr. B. N. Brooke, Birmingham.
Dr. J. C. Brundret, Liverpool.
Dr. K. E. Cooper, Bristol.
Dr. G. W. Harris, Cambridge.
Dr. P. D'Arcy Hart, London.
Dr. J. F. Heggie, London.
Dr. J. W. Howie, Aberdeen.
Dr. M. G. C. Israëls, Manchester.
Dr. A. R. Kelsall, Sheffield.
Mr. A. G. R. Lowdon, Edinburgh.
Dr. F. R. Magarey, Cardiff.
Dr. W. R. M. Morton, Belfast.
Dr. C. L. Oakley, Bromley.
Dr. M. R. Pollock, London.
Dr. I. Rannie, Newcastle-upon-Tyne.
Dr. A. H. T. Robb-Smith, Oxford.
Dr. R. D. Stuart, Glasgow.
Dr. G. R. Tudhope, Dundee.

OPHTHALMIC GROUP COMMITTEE

Dr. R. H. Balfour Barrow, Winchester.
Dr. H. R. Bickerton, Liverpool.
Mr. Nigel Cridland, Southsea, Hants.
Sir Stewart Duke-Elder, London.
Mr. L. P. J. Evans, Birmingham.
Dr. N. P. R. Galloway, Nottingham.
Dr. J. J. Healy, Llanelly.
Mr. F. W. Law, London.
Dr. E. G. Mackie, Sheffield.
Dr. J. Marshall, Glasgow.
Mr. O. Gayer Morgan, London.
Mr. A. McKie Reid, Liverpool.
Dr. R. Gordon Simpson, London.
Dr. C. M. Stevenson, Cambridge.
Mr. F. Oliver Walker, Dartford.
Mr. J. R. Wheeler, Belfast.
Dr. W. Woolley, Bristol.

Appointed by Council of the Faculty of Ophthalmologists:
Mr. G. W. Black, Leeds.
The Hon. G. J. O. Bridgeman, London.
Mr. J. D. M. Cardell, London.
Mr. J. H. Doggart, London.
Mr. O. M. Duthie, Manchester.
Mr. A. B. Nutt, Sheffield.

ORTHOPAEDIC GROUP COMMITTEE

Mr. N. L. Capener, Exeter.
Mr. H. O. Clarke, London.
Mr. V. H. Ellis, London.
Mr. C. G. Irwin, Newcastle-upon-Tyne.

Mr. S. T. Irwin, Belfast.
Mr. S. A. S. Malkin, Nottingham.
Mr. A. Miller, Glasgow.
Mr. A. B. Pain, Leeds.
Professor Sir Harry Platt, Manchester.
Mr. Philip Wiles, London.
Together with the *President for the time being of the British* Orthopaedic Association.

OTOLARYNGOLOGISTS GROUP COMMITTEE

Mr. A. D. Bateman, Bath.
Mr. E. D. D. Davis, London.
Mr. R. L. Flett, Derby.
Mr. R. B. Lumsden, Edinburgh.
Dr. J. E. G. McGibbon, Liverpool.
Mr. F. A. MacLaughlin, Belfast.
Mr. Robert D. Owen, Cardiff.
Mr. E. Cowper Tamplin, Southsea.
Mr. Donald Watson, Bradford.
Dr. Gavin Young, Glasgow.

PATHOLOGISTS GROUP COMMITTEE

Dr. E. N. Allott, Beckenham, Kent.
Professor D. F. Cappell, Glasgow.
Dr. C. E. Dukes, London.
Dr. S. C. Dyke, Wolverhampton.
Dr. R. W. Fairbrother, Manchester.
Dr. J. G. Greenfield, London.
Professor R. J. V. Pulvertaft, London.
Dr. A. F. S. Sladden, Swansea.
Dr. F. B. Smith, Arnside, Via Carnforth, Lancs.

PHYSICAL MEDICINE GROUP COMMITTEE

Dr. R. G. Anderson, Cheltenham.
Dr. L. D. Bailey, Northwood, Middlesex.
Dr. P. Bauwens, London.
Dr. J. B. Burt, Bath.
Dr. F. S. Cooksey, London.
Dr. W. S. C. Copeman, London.
Dr. J. Cowan, Manchester.
Dr. M. H. Jupe, London.
Dr. J. W. T. Patterson, Droitwich.
Dr. W. S. Tegner, London.
Dr. D. Wilson, Bognor Regis.

PSYCHOLOGICAL MEDICINE GROUP COMMITTEE

Dr. N. H. M. Burke, St. Albans, Herts.
Dr. H. Crichton-Miller, Harrow-on-the-Hill.
Professor H. V. Dicks, London.
Dr. P. K. McCowan, Dumfries.
Dr. W. G. Masefield, Eastbourne.
Dr. Doris Odlum, London.
Dr. A. A. W. Petrie, Sutton, Surrey.
Dr. J. R. Rees, London.
Dr. T. P. Rees, Warlingham, Surrey.
Dr. J. Ivison Russell, York.
Dr. W. Rees Thomas, Dorking.

RADIOLOGISTS GROUP COMMITTEE

Dr. J. F. Brailsford, Birmingham.
Dr. S. Whately Davidson, Newcastle-upon-Tyne.
Dr. E. D. Gray, Manchester.
Mr. J. L. A. Grout, Sheffield.
Dr. M. H. Jupe, London.
Dr. Ralston Paterson, Manchester.
Dr. S. Cochrane Shanks, London.
Dr. C. G. Teall, Birmingham.
Professor B. W. Windeyer, London.

SPA PRACTITIONERS GROUP

Dr. R. G. Anderson, Cheltenham.
Dr. F. Clayton, Leamington.
Dr. R. G. Gordon, Bath.
Dr. L. J. Prosser, Harrogate.
Dr. R. W. Stewart, Buxton.
Dr. D. Wilson, Bognor Regis.
Dr. W. Yeoman, Harrogate.

TUBERCULOSIS AND DISEASES OF THE CHEST GROUP COMMITTEE

Shortly to be elected.

VENEREOLOGISTS GROUP COMMITTEE

Mr. R. C. L. Batchelor, Edinburgh.
Dr. A. H. Harkness, London.
Colonel L. W. Harrison, London.
Mr. A. J. King, London.
Dr. S. M. Laird, Ipswich.
Dr. R. Lees, Leeds.
Dr. V. E. Lloyd, London.
Dr. A. E. W. McLachlan, Bristol.
Dr. W. N. Mascall, London.
Dr. I. N. Orpwood Price, London.
Dr. Mary Michael Shaw, London.
Dr. C. H. Wilkie, Leicester.

III. OTHER COMMITTEES

ADVISORY COMMITTEE RE SALARIES OF WHOLE-TIME PUBLIC HEALTH MEDICAL OFFICERS

Dr. C. Metcalfe Brown, Manchester.
Dr. G. F. Buchan, London.
Dr. R. G. Cooke, Derby.
Dr. J. Fenton, London.
Dr. F. Gray, London.
Dr. F. Hall, St. Annes-on-Sea.
Dr. R. H. H. Jolly, Wolverhampton.
Dr. Jean Mackintosh, Birmingham.
Dr. Charles Hill.

REPRESENTATIVE BODY AGENDA COMMITTEE

Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Dr. R. W. McConnel, Wendover, Bucks.
Dr. S. Noy Scott, Plympton, Plymouth.
Dr. R. Cove Smith, London.
Dr. W. Woolley, Bristol.

BUILDING COMMITTEE

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Dr. A. M. A. Moore, London (*Treasurer*).
Dr. Alexander Brown, Linton, Cambs.
Mr. L. Dougal Callander, Doncaster.
Dr. O. C. Carter, Bournemouth
Dr. H. Guy Dain, Birmingham.
Dr. P. J. Gibbons, Liverpool.
Dr. D. F. Hutchinson, London.
Dr. J. G. Thwaites, Brighton.
Dr. H. Vickers, Uxbridge, Middlesex.

COMMITTEE ON THE CARE AND TREATMENT OF THE ELDERLY AND INFIRM

Dr. Janet K. Aitken, London.
The Rt. Hon. Lord Amulree, London.
Dr. A. Greig Anderson, Aberdeen.
Dr. E. B. Brooke, Carshalton.
Sir Ernest Rock Carling, London.
Dr. L. Z. Cosin, Orsett, Essex.
Dr. Mary Esslemont, Aberdeen.
Dr. R. G. Gordon, Bath.
Dr. J. A. Gorsky, London.
Dr. G. MacFeat, Douglas, Lanarks.
Dr. A. T. Rogers, Bromley, Kent.
Dr. W. D. Steel, Worcester.
Dr. F. R. Sturridge, London.
Dr. Marjory Warren, Isleworth, Middlesex.
Chairmen or nominees of the Private Practice, Central Consultants and Specialists, General Medical Services, and Public Health Committees, together with one representative each of the Institute of Almoners, the National Old People's Welfare Committee, and the Queen's Institute of District Nursing.

COMMITTEE ON CONSTITUTIONAL POSITION OF BRANCHES OF THE ASSOCIATION OVERSEAS (OTHER THAN CORPORATE BRANCHES)

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Three members appointed by the Organization Committee:
Dr. F. Gray, London.
Dr. J. A. Pridham, Weymouth.
Dr. D. S. Saklatvala, West Bromwich.
Together with three members to be appointed by the Colonies and Dependencies Committee, with power to co-opt.

JOINT COMMITTTEE ON ASSOCIATION OF GENERAL PRACTITIONERS WITH HOSPITALS

Three representatives appointed by each of the following Committees: Health Centre, Private Practice, Public Health, and General Medical Services.
Six representatives appointed by the Central Consultants and Specialists Committee.

COMPENSATION AND SUPERANNUATION COMMITTEE

Three members to be appointed by the General Medical Services Committee.
Three members to be appointed by the Public Health Committee.
Three members to be appointed by the Central Consultants and Specialists Committee.

CORONERS ACTS COMMITTEE

Six members to be appointed by the Private Practice Committee.
Chairman or nominee of the Pathologists Group Committee.
Together with four members appointed by the Coroners' Society for England and Wales.

FILM COMMITTEE

Dr. C. W. C. Bain, Harrogate (*President*).
Mr. A. Lawrence Abel, London.
Sir A. Biggam, Edinburgh.
Mr. V. Zachary Cope, London.
Dr. J. Cotterell, Grimsby.
Dr. J. A. Gorsky, London.
Dr. P. Hansell, London.
Professor H. C. Hewer, London.
Dr. R. P. St. L. Liston, Tunbridge Wells.
Dr. R. C. Mackeith, London.
Professor G. P. Meredith, Leeds.
Mr. R. L. Newell, Manchester.
Dr. R. G. Ollerenshaw, Manchester.
Mr. H. Reid, Liverpool.
Dr. J. B. Wrathall Rowe, Wealdstone, Middlesex.
Dr. C. M. Seward, Exeter.
Mr. A. Dickson Wright, London.
Chairman or nominee of the Science Committee, together with two representatives of the B.M.S.A.

HEALTH CENTRE COMMITTEE

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Dr. G. O. Barber, Dunmow, Essex.
Dr. A. Beauchamp, Solihull, Warwicks.
Professor J. S. English, Newtownards, Co. Down.
Dr. P. J. Gibbons, Liverpool.
Dr. J. A. Gorsky, London.
Mr. A. Staveley Gough, Watford.
Dr. C. F. R. Killick, Williton, Somerset.
Mr. G. Lowe, Tiverton, Devon.
Dr. G. MacFeat, Douglas, Lanarks.
Dr. T. W. Morgan, New Malden, Surrey.
Mr. A. E. Porritt, London.
Dr. A. Talbot Rogers, Bromley, Kent.
Dr. J. A. Scott, London.
Dr. H. R. Youngman, Cambridge.
Together with a representative of the General Medical Services Committee and observers of the Ministry of Health.

INTERNATIONAL RELATIONS COMMITTEE

Dr C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Mr. A. Lawrence Abel, London.
Dr. J. Clayre, Southampton.
Dr. Alfred Cox, London.
Dr. H. Guy Dain, Birmingham.
Dr. S. C. Dyke, Wolverhampton.
Dr. J. C. Matthews, Downton, Wilts.
Dr. G. de Swiet, London.
Chairmen or nominees of the Organization, Journal, Science, General Medical Services, and Colonies and Dependencies Committees, Chairman or nominee of Committee of Management of Empire Medical Advisory Bureau, together with a representative of the British Council and of the B.M.S.A.

COMMITTTEE ON NURSING

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Dr. E. B. Brooke, Carshalton.
Dr. Mary Esslemont, Aberdeen.
Dr. A. F. Foster-Carter, Aldershot.
Dr. J. A. Gorsky, London.
Mr. A. Staveley Gough, Watford.
Dr. C. G. Martin, London.
Dr. W. G. Masefield, Eastbourne.
Dr. J. B. Wrathall Rowe, Wealdstone, Middlesex.
Dr. Alexander Smith, East Kilbride, Lanarks.
Mr. J. P. Wetenhall, London.
Chairmen or nominees of the Public Health, Scottish, Central Consultants and Specialists, Private Practice, and Occupational Health Committees.
Two members nominated by the Royal College of Nursing.
One member nominated by the King Edward's Hospital Fund for London.
With power to co-opt four members.

PARLIAMENTARY ELECTIONS COMMITTEE

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Dr. S. F. L. Dahne, Reading.
Dr. H. Guy Dain, Birmingham.
Dr. H. R. Frederick, Port Talbot, Glam.
Dr. F. Gray, London.
Dr. J. G. Thwaites, Brighton.
Dr. S. Wand, Birmingham.
Representative of Medical Women's Federation.

JOINT COMMITTEE ON FEES FOR PART-TIME WORK UNDER LOCAL AUTHORITIES

Appointed by Central Consultants and Specialists Committee:
Mr. A. Lawrence Abel, London.
Mr. R. L. Newell, Cheadle, Cheshire.
Mr. A. Dickson Wright, London.

Appointed by Public Health Committee:
Dr. G. F. Buchan, London.
Dr. James Fenton, London.
Dr. R. H. H. Jolly, Wolverhampton.

Appointed by Private Practice Committee:
Dr. E. W. Goodwin, Leicester.
Dr. J. A. Gorsky, London.
Dr. I. D. Grant, Pollokshields, Glasgow.

COMMITTEE ON NUTRITION

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Mrs. M. C. Bowley, Harpenden, Herts.
Dr. G. F. Buchan, London.
Dr. Harriette Chick, Cambridge.
Professor S. J. Cowell, London.
Professor G. P. Crowden, London.
Sir Jack Drummond, Nottingham.
Professor R. W. B. Ellis, Edinburgh.
Dr. R. G. Gordon, Bath.
Mrs. E. Hedley-Prole, London.
The Rt. Hon. Lord Horder, London.
Dr. F. Avery Jones, London.
Dr. Jean Mackintosh, Birmingham.
Professor J. R. Marrack, London.
Professor V. H. Mottram, Shaftesbury, Dorset.
Dr. R. A. Murray Scott, Leeds.
Dr. H. M. Sinclair, Oxford.
Dr. R. E. Smith, Rugby.
Dr. Donald Stewart, Birmingham.
Dr. J. G. Thwaites, Brighton.
Professor John Yudkin, London.
Together with observers from certain Government Departments.

COMMITTEE ON PATENTING IN THE MEDICAL FIELD

Three members to be appointed by the Science Committee.
Three members to be appointed by the Central Ethical Committee.
With power to co-opt.

COMMITTEE ON THE POSTGRADUATE EDUCATION OF GENERAL PRACTITIONERS

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Mr. A. Lawrence Abel, London.
Dr. Janet K. Aitken, London.
Dr. J. T. Baldwin, Penicuik, Midlothian.
Dr. G. W. Bamber, Liverpool.
Dr. G. O. Barber, Great Dunmow, Essex.
Sir Alexander Biggam, Edinburgh.
Mr. Norman Capener, Exeter.
Professor Sir Henry Cohen, Liverpool.
Mr. V. Zachary Cope, London.
Dr. H. Guy Dain, Birmingham.

Dr. Hugh Davies, London.
Dr. R. G. Gordon, Bath.
Dr. K. H. C. Hester, Harpenden, Herts.
Dr. R. P. Liston, Tunbridge Wells.
Professor Hilda N. Lloyd, Birmingham.
Mr. J. D. McLaggan, London.
Miss Ida Mann, London.
Dr. J. I. Milne, Manchester.
Dr. C. E. Newman, London.
Sir Philip Panton, London.
Sir Leonard Parsons, Birmingham.
Dr. I. C. B. Pearce, Diss, Norfolk.
Dr. C. M. Seward, Exeter.
Dr. Donald Stewart, Birmingham.
Mr. J. W. Tudor Thomas, Cardiff.
Dr. C. W. Walker, Cambridge.
Professor B. W. Windeyer, London.
Professor G. M. Wishart, Glasgow.

PROPRIETARY MEDICINES COMMITTEE

Two Representatives of Central Ethical Committee:
Dr. E. C. Dawson, Derby.
Dr. N. E. Waterfield, Little Bookham, Surrey.

Two Representatives of Journal Committee:
Dr. O. C. Carter, Bournemouth.
Dr. S. Noy Scott, Plympton, Plymouth.

Two Representatives of Private Practice Committee:
Dr. R. Forbes, London.
Dr. H. H. D. Sutherland, London.

Two Representatives of Science Committee:
Mr. V. Zachary Cope, London.
Dr. R. P. St. L. Liston, Tunbridge Wells.

Together with: Dr. G. R. Boyes, London. Mr. W. K. Fitch, London. Dr. F. H. K. Green, London. Professor A. A. Moncrieff, London.

PUBLIC RELATIONS COMMITTEE

Dr. E. A. Gregg, London (*Chairman of Council*).
Mr. A. M. A. Moore, London (*Treasurer*).
Dr. H. Guy Dain, Birmingham.
Dr. James Fenton, London.
Dr. F. Gray, London.
Dr. J. T. McCutcheon, Glasgow.
Six Representatives to be appointed by the General Medical Services Committee.

COMMITTEE ON RELATIONSHIP OF AUTONOMOUS BODIES

Dr. E. A. Gregg, London (*Chairman of Council*).
Mr. A. Lawrence Abel, London.
Dr. J. A. Brown, Birmingham.
Dr. O. C. Carter, Bournemouth.
Dr. H. Guy Dain, Birmingham.
Dr. James Fenton, London.
Dr. R. G. Gordon, Bath.
Dr. F. Gray, London.
Dr. W. Jope, High Blantyre, Lanarks.
Dr. J. B. Miller, Bishopbriggs, Lanarks.
Mr. R. L. Newell, Cheadle, Cheshire.
Dr. J. A. Pridham, Weymouth.
Dr. S. Wand, Birmingham.
Dr. N. E. Waterfield, Little Bookham, Surrey.
Sir Lionel Whitby, Cambridge.

COMMITTEE ON SALARIES OF MEDICALLY QUALIFIED TEACHERS, ETC.

Dr E. A. Gregg, London (*Chairman of Council*).
Dr. Janet K. Aitken, London.
Dr. James Fenton, London.
Professor A. C. Frazer, Birmingham.
Dr. G. W. Harris, Cambridge.
Dr. P. D'Arcy Hart, London.
Professor A. St. G. Huggett, London
Dr. M. C. G. Israëls, Manchester.
Dr. I. Rannie, Newcastle-upon-Tyne.
Dr. S. Cochrane Shanks, London.
Dr. R. D. Stuart, Glasgow.
Sir Lionel Whitby, Cambridge.

WAR MEMORIAL COMMITTEE

Dr. C. W. C. Bain, Harrogate (*President*).
Dr. E. A. Gregg, London (*Chairman of Council*).
Dr. J. A. Brown, Birmingham (*Acting Chairman of Representative Body*).
Mr. A. M. A. Moore, London (*Treasurer*).
Dr. R. W. Cockshut, London.
Dr. H. Guy Dain, Birmingham.
Together with the Chairmen or nominees of the Building, Armed Forces, Charities, and Organization Committees.
With power to co-opt.

COMMITTEE ON PSYCHIATRY AND THE LAW

Dr. F. Bodman, Bristol.
Dr. Denis Carroll, London.
Dr. R. G. Gordon, Bath.
Dr. Hermann Mannheim, London.
Mr. Claud Mullins, Petworth, Sussex.
Dr. Doris Odlum, London.
Dr. T. P. Rees, Warlingham, Surrey.
Dr. J. G. Thwaites, Brighton.
With Representatives of the Magistrates' Association.

JOINT COMMITTEE OF B.M.A. AND T.U.C.

Mr. A. Lawrence Abel, London.
Dr. R. W. Cockshut, London.
Dr. H. Guy Dain, Birmingham.
Dr. F. Gray, London.
Dr. E. A. Gregg, London.
Dr. J. A. L. Vaughan Jones, Leeds.
Mr. R. L. Newell, Cheadle, Cheshire.
Dr. S. Wand, Birmingham.

JOINT COMMITTEE OF B.M.A. AND NATIONAL VETERINARY MEDICAL ASSOCIATION

Mr. A. Lawrence Abel, London.
Dr. C. Metcalfe Brown, Manchester.
Dr. W. A. Bullough, Colchester.
Dr. James Fenton, London.
Dr. J. M. Gibson, Huddersfield.
Dr. J. Kelman, Perth.
Dr. Wyndham Parker, Worcester.
Professor G. S. Wilson, London.

JOINT COMMITTEE OF B.M.A. WITH PHARMACEUTICAL SOCIETY

Dr. E. A. Gregg, London (*Chairman of Council*).
Three members appointed by the Private Practice Committee.
Three members appointed by the General Medical Services Committee.
One member appointed by the Scottish Committee.

JOINT FORMULARY COMMITTEE OF B.M.A. AND PHARMACEUTICAL SOCIETY

Four representatives appointed by the General Medical Services Committee, two by the Central Consultants and Specialists Committee, two by the Science Committee; together with two representatives appointed by the Royal College of Physicians (Dr. P. Hamill and Dr. D. Hunter), and representatives appointed by the Ministry of Health, and Service Departments.
With power to co-opt.

B.M.A. AND ROYAL COLLEGE OF NURSING LIAISON COMMITTEE

Dr. E. A. Gregg, London (*Chairman of Council*).
Mr. A. Staveley Gough, Watford.
Dr. H. Joules, London.
Mr. M. P. Reddington, London.
Chairman or nominees of the Central Consultants and Specialists, Private Practice, Central Ethical, Occupational Health, Nursing, and Public Health Committees.

MEDICAL CERTIFICATES IN PREGNANCY

With a view to reducing the amount of medical certification the Ministry of National Insurance has changed the procedure for dealing with cases where sickness benefit is claimed on the grounds of incapacity due to pregnancy.

Broadly speaking, these cases fall into two classes—namely, those women who claim sickness benefit from the sixth week before expected confinement and those who claim sickness benefit at an earlier stage. In the former class of case the fact that pregnancy is so advanced is normally acceptable as sufficient evidence of incapacity for work. In the latter it is necessary to consider whether her pregnancy causes the woman to be incapable of work.

It may happen that the woman, in order to claim maternity benefit, has obtained and lodged with the M.N.I. local office a medical certificate of pregnancy on Form B.M.4 or B.M.4(Rev.) (Claim to Maternity Benefit) at some time up to 11 weeks before the expected confinement. If her claim to maternity allowance fails because she does not satisfy the insurance-contribution conditions and, as an alternative, she then claims sickness benefit in the period beginning six weeks before the expected confinement, the one medical certificate—either on Form B.M.4 (or B.M.4(Rev.)) or on an ordinary medical certificate—will be accepted as sufficient evidence of incapacity until two weeks after the actual confinement. Therefore in the cases

during the whole of this period beginning with the sixth week before expected confinement and ending two weeks after the actual confinement there will be no need for weekly medical certificates.

Where the woman claims sickness benefit because of incapacity due to pregnancy at any time earlier than six weeks before the expected week of confinement, the usual weekly medical certificates of incapacity will be required only until the sixth week before the expected date of confinement, when, provided that she sends in a claim on Form B.M.4 or B.M.4 (Rev.), the woman will get either maternity allowance or sickness benefit according to the particular insurance qualifications in her case.

When issuing medical certificates of incapacity due to pregnancy it will help the woman in claiming benefit if the doctor gives the expected date of confinement and a brief note of the kind of work which the woman normally does. This information is particularly helpful in the case where the woman claims sickness benefit at any time earlier than six weeks before expected confinement.

SURVEY OF GENERAL PRACTICE

The Medical Practices Committee has issued the following amendments to the four schedules compiled from its survey (*Supplement*, Aug. 6, p. 70).

Schedule 1

Counties

ADDITIONS

Essex.—Barking, Chelmsford with Great Baddow, Chingford, Dagenham, Dovercourt and Harwich, Dunmow, Grays, Hornchurch with Harold Wood and Upminster, Laindon, Purfleet, Rainham, Rayleigh, Romford and Gidea Park, Seven Kings, Tilbury, Walthamstow, Wickford and Pitsea, Writtle.

DELETIONS

Soke of Peterborough.—Whittlesey and Market Deeping.

Schedule 2

Counties

ADDITIONS

Essex.—Abridge, Billericay, Braintree, Brentwood and Shenfield, Brightlingsea, Buckhurst Hill, Burnham-on-Crouch, Canvey Island, Chigwell and Chigwell Row, Clacton-on-Sea, Colchester, Hadleigh, Halstead, Harlow, Higham's Park, Ilford with Chadwell Heath, Barkingside, and Goodmayes, Kelvedon, Leyton, Leytonstone, Maldon, Manningtree, Newport, Ongar, Rochford, Sible Hedingham and Castle Hedingham, South Benfleet, Stanford-le-Hope and Corringham, Tiptree, Waltham Abbey, Wanstead, West Bergholt, Witham, Wivenhoe.

Oxford County and City.—Kidlington.

Carmarthenshire.—Newcastle Emlyn.

DELETIONS

Isle of Ely.—Long Sutton, Mildenhall, Peterborough, Ramsey, Upwell.

Cardiganshire.—Newcastle Emlyn.

CORRECTION

Yorkshire (West Riding).—Morley should be borough and not rural district.

Schedule 3

Counties

ADDITIONS

Essex.—Epping, Frinton-on-Sea and Walton, Great Wakering, Loughton, Saffron Walden, Stansted, Thorpe-le-Soken, Tollesbury, Woodford and Woodford Green, Woodford Bridge, Woodford South.

DELETIONS

Oxford County and City.—Kidlington.

Warwickshire.—Alcester Rural District.

Schedule 4

Counties

ADDITIONS

Devon and Exeter.—Combe Martin.

Essex.—Earls Colne, Great Bentley, Hockley, Hatfield Broad Oak, Ingatestone and Stock, Roydon, Southminster, Thaxted, Tillingham, West Mersea.

Warwickshire.—Alcester Rural District.

SUPERANNUATION FOR PART-TIME SPECIALISTS

OPTING OUT

The Ministry of Health has issued a leaflet (No. SDDA) setting out the circumstances under which part-time specialists in contract with hospital boards may opt out of the N.H.S. superannuation scheme.

The option is limited to *part-time* specialists, and those who wish to contract out must do so before Nov. 1, 1949, by giving written notice to the Ministry of Health, Health Services Superannuation Division, Honeypot Lane, Stanmore, Middlesex, on Form S.D.28A, which is obtainable from regional hospital boards or boards of governors of teaching hospitals. Copies of the leaflet SDDA, which is reproduced below, may be obtained from the same authorities.

Option Available to Persons Rendering Part-time Specialist Services who hold Life Assurance Policies

The option already given to medical and dental practitioners is now available to officers who joined the National Health Service on July 5, 1948, as persons rendering part-time specialist services and who were, at that date, committed to paying substantial premiums on life assurance policies.

The choice lies between (*a*) paying contributions and qualifying for benefits under the Health Service scheme, and (*b*) contracting out of that scheme and receiving as from Aug. 1, 1949, an amount equal to 8% of remuneration as a part-time specialist towards the maintenance of approved assurance policies.

The exercise of this option will be subject to the following conditions, which are substantially as discussed with representatives of the medical and dental professions when the option was given to practitioners. The object of these conditions is to secure that the payments are related to current policies giving cover broadly equivalent to that in the Health Service scheme:

(*a*) The policies must be endowment assurances or deferred annuity policies.

(*b*) The policies must not mature at an earlier age than 60. Where a policy would under its original terms have matured before age 60 it can be accepted if its terms are modified so that it matures at or after age 60.

(*c*) (i) The premiums (or total premiums) must not be less than £150 per annum. (ii) Alternatively, if the total annual premiums on existing policies are less than £150 per annum but not less than £50 per annum, these policies will be recognized on condition that the part-time specialist takes out, when requested to do so by the Ministry, a further policy which will bring the total premium to at least £150 per annum on policies satisfying the conditions set out in (*a*) and (*b*) above.

(*d*) The policies must not be assigned to any other person, or surrendered before maturity.

(*e*) Payment by the Minister of an amount equal to 8% of the remuneration as a part-time specialist will continue only so long as the premiums on the policies continue to be payable, and in any case it cannot continue later than the specialist's 70th birthday.

(*f*) The policies must be produced for inspection on a request by the Minister, or by the regional hospital board or board of governors on his behalf. Alternatively, a statement from the assurance company as to the nature of the policies may be submitted.

(*g*) Premium receipts must be submitted to the Minister, or to the regional hospital board or board of governors, for examination within one month after the date on which each payment of premium falls due.

Comparison of Advantages.—Before deciding whether or not to exercise this option a part-time specialist will wish to weigh the relative advantages of the courses open to him. Attention is therefore invited to the booklet "Superannuation Scheme for Those Engaged in the National Health Service—An Explanation," a copy of which was given to all entrants to the Service. Sections B and C of that booklet outline the contributions and benefits, and paras. 1, 5, 7, 16, and 25 deal with special conditions applicable to practitioners and part-time specialists who are subject to the scheme. Para. 16 of the booklet shows how benefits are calculated in the case of part-time specialists and should be borne in mind when reading the other paragraphs in Section C. Amending regulations now enable years of service up to five years after "pensionable age" to count towards pension, to a maximum of 45.

How to Exercise the Option.—A part-time specialist who wishes to contract out of the Health Service scheme may do so by giving written notice on a form (Form S.D.28A) obtainable from the regional hospital board or board of governors before Nov. 1, 1949.

If the option is exercised the part-time specialist will remain out of the Health Service scheme in respect of all future work either as a part-time specialist *or* as a practitioner on the list of the executive council.

A part-time specialist who is also a practitioner on the list of an executive council may already have elected to remain out of the Health Service scheme in his work as a practitioner. If that election was accepted he will now automatically be out of the scheme in his employment as a part-time specialist, and to ensure that he is paid the "employer's 8%" in respect of that employment he should inform the regional board or board of governors of his position.

Part-time specialists who hold appointments with more than one board need complete one form only.

Contributions Already Paid.—Any contributions already paid into the scheme by a part-time specialist who now comes out of the scheme will be refunded.

SICKNESS BENEFITS FOR IN-PATIENTS

Under regulations which come into force on Sept. 5 the National Insurance sickness benefit of a patient with a dependant will be reduced by 5s. a week (instead of the 10s. as at present) after he has been maintained free of charge under the National Health Service or by the Ministry of Pensions in a hospital for two months. There will be no further reduction if the beneficiary has arranged for all but 5s. of his benefit (which can be paid to him for personal expenditure) to be paid to the dependant. If he has no dependants his benefit will be reduced by 10s. a week after two months in hospital. After a year his benefit will be reduced to 5s., but on discharge a resettlement sum will be available. After the second year his benefit will be finally reduced to 5s. a week. Patients suffering from any form of respiratory tuberculosis will be able to receive 10s. (instead of 5s.) while they are in hospital, but the amount which is paid over to their dependants, or which can be paid on discharge, will be correspondingly reduced.

TRAINING OF ASSISTANTS IN SCOTLAND

The Department of Health for Scotland announces that general medical practitioners who wish to undertake the training of assistants in their practices, and claim special payments on this account, will shortly be invited to apply for recognition as trainer-practitioners. Recognition for this purpose will be given by regional selection committees appointed by the Secretary of State in consultation with the representative organization of the profession.

A practitioner who has been recognized by the selection committee will himself engage his assistant, and will claim a training grant from his local executive council. The grant will comprise :

(1) A training fee for the practitioner himself at the rate of £150 a year;

(2) Recoupment (up to a maximum of £700 per annum) of the salary paid by the practitioner to the assistant; and

(3) If necessary, an allowance for a motor-car for the assistant.

A grant will be payable only where a practitioner undertakes the training in general medical practice of a recently qualified doctor, and no increase in the number of patients on the practitioner's list will be permissible on account of the engagement of the assistant.

Applications for recognition will be made to the Regional Medical Officers of the Department of Health for Scotland, at Edinburgh, Glasgow, Dundee, Aberdeen, and Inverness, who will act as secretaries to the various regional selection committees.

These arrangements do not apply to the employment of an assistant, whether experienced or inexperienced, in a practice under ordinary conditions. No grant will be payable in such a case, and the practitioner concerned will not require to be recognized by the regional selection committee.

The conditions governing the training of assistants in England and Wales were published in the *Supplement* of Oct. 30, 1948 (p. 149).

RETURNING MEDICINE BOTTLES

CONTAINER ALLOWANCE REDUCED

The container allowance on medicine bottles, boxes, etc., will be reduced from 2½d. to 1½d. per prescription from Sept. 1. It is estimated that this measure will save the Exchequer at least £800,000 a year, but it will mean a corresponding loss to chemists unless the public co-operate by returning medicine bottles. The Minister of Health has taken this decision in agreement with the Central National Health Service (Chemist-Contractors) Committee.

A publicity campaign will be held to encourage the public to return to their chemists used medicine bottles in a clean condition.

HOSPITAL ORGANIZATION

HOUSE COMMITTEES

The Minister of Health has asked hospital boards to set up house committees, which will be committees of boards of governors or subcommittees of management committees. It will be for the parent body to decide whether it will delegate functions to its house committee—that is, give it final responsibility for decisions in defined spheres; or make decisions or recommendations of the house committee subject to confirmation by the parent body; or combine the two methods.

The Minister says that the value of house committees lies mainly in the field of overseeing the daily conduct of the hospital and making recommendations to the management committee or board of governors for those bodies to decide. The committee should also act as a link between the local community and the hospital and provide an opportunity for those interested to take part in hospital work. He considers that the powers delegated to house committees should not exceed the following :

General.—(i) Visiting, supervising the *welfare* of patients and staff, and making recommendations to the management committee or board on the day-to-day running of the hospital (but not taking executive action). (ii) Recommending developments or new policy to the management committee or board.

Financial.—(i) Managing the individual hospital's share of the management committee's or board's "free" money. (House committees cannot, however, legally accept or hold gifts, etc., under sections 59 (1) and 60. These must be held in the name of the management committee or board of governors.) (ii) House committees should not be empowered to incur on their own authority any expenditure from Exchequer funds.

When appointing members of house committees, the parent body should consult appropriate local organizations—for example, local authorities, trades councils, and women's and other voluntary organizations.

MEDICAL AUXILIARY WORKERS

ADVISORY COMMITTEES

Vacancies on the committees recently set up (*Supplement*, July 9, p. 44) by the Minister of Health and the Secretary of State for Scotland to review questions of recruitment, training, and qualifications of medical auxiliary workers in the National Health Service have now been filled by the following appointments :

Laboratory Technicians.—Professor L. P. GARROD, Dr. J. E. MCCARTNEY.

Almoners.—Professor C. WILSON.

Speech Therapist.—Miss E. Macleod.

Mr. T. C. L. Nicole, of the Ministry of Health, has succeeded Mr. J. G. Paterson as secretary of the eight committees, which are under the chairmanship of Mr. V. Zachary Cope, and Miss Gaffney, also of the Ministry, has been nominated as assistant secretary.

MARRIAGE ALLOWANCES OF NATIONAL SERVICE OFFICERS IN THE ARMED FORCES

A reply has now been received to the Association's protest at the Government's decision that National Service officers should not be eligible to receive the increased marriage allowances which have been payable since November, 1948, to regular and short-service officers.

The Ministry of Defence states that this decision was made because officers called up for service under the National Service Acts since Jan. 1, 1947, are eligible for National Service grants. The object of these grants is to relieve, within certain limits, cases of financial difficulty where the ordinary Service emoluments of officers serving compulsorily are insufficient to enable them to meet their obligations to their families and other dependants. For example, a wife and family whose living standards before service began cannot be maintained on marriage allowance and a reasonable allotment from the husband's Service pay. (It is also open to single officers in appropriate circumstances to apply for National Service grants.)

The maximum grant awarded is £3 a week, and a grant is treated as taxable income. The scheme is administered by the Ministry of Pensions. Application for a National Service grant must be made on Form N.S.G.21, which is obtainable by the officer from his unit.

PRACTICE OF ORTHOPTICS

VIEWS OF B.O.A.

The council of the British Optical Association has issued a reply to the memorandum on orthoptics prepared by the Faculty of Ophthalmologists and reported in the *Supplement* of June 18 (p. 349). The B.O.A. states that the Faculty's memorandum purports to compare the training of holders of the Diploma of British Orthoptists with that for the Diploma of Orthoptics of the British Optical Association (D.Orth.), and that it implies the former has certain advantages for three main reasons: (*a*) length of training; (b) clinical experience; (*c*) experience with surgical cases.

The British Optical Association says that the D.B.O. course until very recently was of only 12 months' duration, and consequently very few holders of the D.B.O. would have taken the present two-years course—the time referred to in the Faculty's memorandum. Moreover, the student for the D.Orth. must already have qualified in ophthalmic optics before entering for the examination. The standard of entry to the optical profession is that of the school certificate or its equivalent. The minimum requirement for training for the B.O.A. and similar examinations occupies at present three years full-time and will be extended to four years full-time from the autumn of this year, when one year will provide clinical experience.

The B.O.A. contends that the present D.Orth. course is a postgraduate one for practitioners who have already covered much of the subject, and that the diploma cannot be gained under four years, five years being a more general minimum period. Most opticians do not enter for it until they have obtained considerable experience in practice. At the last examination the average age of entrants was 36.8 years. The B.O.A. lists some medical men, including ophthalmic surgeons, who have acted as examiners for the D.Orth. and Fellowship examinations. "Thus every D.Orth. candidate has had to satisfy a medical examiner in some section of his examination."

Discussing clinical experience, the B.O.A. states that the Faculty's memorandum ignores the fact that ophthalmic opticians have organized their own orthoptic clinics. For the past 20 years the London Refraction Hospital has had its own orthoptics department. The hospital was founded in 1922, reconstituted by order of the Charity Commission in 1938, and is registered under that name. It was bombed during the war, but has now been re-equipped, and work has never ceased there. Children's attendances there at the two weekly children's clinics numbered over 2,700 in 1948, a large proportion of these being cases of squint. Considerable numbers attended on other days, and many older patients had squint or oculomotor anomalies.

The B.O.A. considers that it might be inferred from the Faculty's memorandum that ophthalmic opticians never refer squint cases for surgical treatment, but this is far from the truth. In training, considerable attention is given to the selection of cases for orthoptic training, to contraindications, and to the advantages of surgical treatment in certain cases. There is a substantial degree of cordial co-operation with ophthalmic surgeons. If facilities are forthcoming the B.O.A. is willing to consider making it a requirement that candidates, before examination, shall attend, for an agreed number of sessions, medical clinics where the surgical treatment of squint and heterophoria is carried out.

The B.O.A. complains that the importance of refraction in the treatment of orthoptic cases is not mentioned in the Faculty's memorandum, and it finds it difficult to understand why the memorandum does not refer to the orthoptic treatment of heterophoria "until it is remembered that heterophoria and refraction are so closely related in many cases that the one cannot be considered without the other, and that therefore the optician is the practitioner best equipped to deal with such cases."

The best interests of the public, says the B.O.A., will not be served by assigning the direction and control of ophthalmic opticians to medicine and making the optician orthoptist a medical auxiliary. "If proof were needed of the danger of such a step it is provided by the Faculty's memorandum itself, in which the medical aspect is not merely given precedence over, but is stressed almost to the complete exclusion of, all other methods used in orthoptics."

HEARD AT HEADQUARTERS

Telling the Americans

The theme of Sir Luke Fildes's picture, "The Doctor," which went to the heart of the British public half a century or more ago, has been adopted by the Americans in their campaign against socialized medicine. Mammoth reproductions of the picture—even, we believe, illuminations of it in the Piccadilly Circus style—have made their appearance, carrying the slogan, "Keep Politics out of this Picture." Our colleagues in the States can be trusted to exploit the arts of the publicity campaigner to the full. When Mr. Lawrence Abel went over there a month or two ago he delivered an address on the Health Service in Great Britain. On the following day he was required to deliver it again with three or four microphones in front of him, and a record was made of it so that his speech could be heard all over the States. One of the records is in this country, and we have heard Mr. Abel's voice putting the case with fervour.

Questions Answered

Retirement of Partner

Q.—*I am in partnership with my father. Half of our patients are on his list and half on mine. What happens to the patients on my father's list on his retirement or death? Do they automatically come on to mine, or are they told to choose any G.P. they wish?*

A.—Much would depend on the circumstances, but, on the assumption that the total list does not exceed the maximum of 4,000, and that another partner or assistant would not be required, the usual procedure would be that notification would be sent to patients on the retiring partner's list informing them that unless they select another doctor within one month they will be placed on the list of the continuing partner.

Correspondence

Distinction Awards and Grading

SIR,—As a member of a regional consultants committee and of the medical committee of a specialist postgraduate medical school I have been unable to obtain satisfactory information on certain problems which seem to me important.

The Spens Report divides medical men into general practitioners and specialists or consultants; it provides steps by which consultant status may be achieved; it grades the individual and recommends distinction awards. The distinction awards are to be granted to 34% of consultants in fixed proportions. The Spens Committee states that part-time service is to be assessed on a sessional basis; it appears to have overlooked the fact that a distinction award cannot be granted to a fraction of a person, and strange possibilities arise from this omission.

If we suppose that there are 100 consultants and give the awards to 34 whole-time workers, the remainder each doing one session a week, the distinction awards so given will cost the Treasury about 33.5% of the total salaries for the group of one hundred if the whole-timers each receive £2,500 a year salary and each of the part-timers $\frac{4}{44}$ of that amount. If, however, the 34 distinction awards are given to consultants doing one session a week and the rest of the hundred are whole-time workers, the cost of the distinction awards to the Treasury is about 2.3% of the total basic salary for the group. Either of these interpretations would seem to be in accord with the Report.

It seems elementary that consultants who have to look to these awards as the only means of recognizing exceptional ability should be protected by a clear understanding. The awards represent 14% of the total basic salary if only whole-time workers are considered, and this fraction of the total basic salary paid to consultants, both sessional and whole-time, might be set aside as a fund out of which the distinction awards are to be paid. This would secure that the profession actually receives the money to which it is entitled. It might also provide a pool out of which these awards could be paid uniformly in the future. Otherwise, once the distinction awards are given, we may find ourselves "waiting for dead men's shoes."

An aspect of distinction awards causing anxiety is the belief that these are to be distributed globally, so that it is thought possible that the smaller specialties may not receive the share of awards which is due to them on a numerical basis. If this should happen it seems inevitable that the more able consultants will shun the less favoured specialties. Another disturbing belief is that awards are to be made on a regional rather than a national basis. This might nullify the intention that the awards should be made in recognition of individual distinction and would make them, in effect, a political weapon forcing the best men away from the recognized centres of medical learning. This has even been acclaimed as desirable. But medical culture and science exist in "schools" for the very reason that in the association of exceptional minds is to be found the key to progress. An official statement on these matters is surely overdue.

The Spens Report grades the individual, not the post, and this principle has been reiterated by the Ministry: "Proper assessment can be arrived at only after consideration by professional advisers of the qualifications and experience of each practitioner." There can be no escape from the assumption that an individual, on his own merit, is or is not a consultant. In grading a man as an S.H.M.O. the assessors are stating quite definitely, "This man is not of consultant status." It follows logically that no one can be both a consultant and an S.H.M.O., yet in ophthalmology this anomaly occurs frequently. If a consultant obtains a distinction award, will the award be payable in respect of those sessions in which he is graded S.H.M.O.? And if not, why not?

In ophthalmology there will be scope for only about one in ten whole-time specialists to undertake operating. By custom this small group has come to have exclusive charge of ophthalmic beds in hospitals. Ophthalmology is essentially a clinical specialty, and the practitioner who has done one or more year's postgraduate training and obtained a diploma in ophthalmology, and who devotes his whole professional life to his subject, may fairly claim to be a specialist and to be entitled to monetary recognition of his postgraduate work.

Yet the application of this simple formula would create something like anarchy. It would mean that in our eye hospitals the surgical staff, usually with higher qualifications and bearing full responsibility, would receive the same remuneration as the permanent clinical assistants in out-patients.

To make these "clinical specialists" "registrars" would be dishonest: there will never be surgical posts for them. To make them S.H.M.O.s degrades them from the rank of specialist to which they believe themselves entitled by "qualifications and experience." Not only so, but as S.H.M.O.s, unless they are at the top of the salary scale, they are actually paid less than a general practitioner doing an occasional ophthalmic clinic. Unless this problem is solved ophthalmology will not attract the specialists—1,000 is the number officially envisaged—necessary for the N.H.S. to function effectively.

It is impossible to make the facts of ophthalmology fit the present scheme. At least two separate groups must be provided for: Registrars taking the Fellowship with ophthalmology, whose numbers must be related to the consultant posts available (and these may be less than 100 on a whole-time basis, with a replacement rate of five or less per annum); and a second registrar group taking the D.O. whose professional life will be that of clinical specialists in ophthalmology. It is urgently necessary that provision be made for the second and much larger group; at present both recognition of specialist status and adequate remuneration are lacking.

Ophthalmologists, and, I suspect, other specialists, cannot all be fitted into the Procrustean bed provided without such serious mutilation as may endanger their professional survival. It is necessary to modify this rigid framework, and this may well be achieved, since the modern Procrustes is concerned that his victims should survive.—I am, etc.,

London, W.1. FREDERICK RIDLEY.

Qualifications of Specialists

SIR,—In your leading article (*Journal*, July 23, p. 220) entitled "The Grading of Specialists" it is written, "Could it be said, for example, that an assistant medical officer in an isolation hospital should be designated as specialist and be paid in the terms of the Spens Report? The same question may also be asked of men similarly placed in sanatoria and mental hospitals."

May I submit that nobody in any branch of the hospital service would wish that an assistant medical officer should be so designated and paid, for, being an assistant medical officer, he would not have attained to the necessary experience and skill. It becomes an injustice, however, when the claims of senior and more experienced officers are ignored. It becomes a grave injustice when junior medical staff are graded higher than such senior officers at the same hospital or their more experienced colleagues in the same specialty in the same region, but this is what is being done by assessment committees in many regions if my information is correct, and I have no reason to doubt its being so.

It is because of differences in interpretation that your correspondents have written asking that the B.M.A. "should act to put matters right." To whom else can they appeal? These differences in interpretation would not have arisen if simple standards, openly declared and generally agreed to, had existed for the observance of all assessment committees. In the absence of such standards all kinds of weird rumours tend to appear.

Now that the Joint Committee has settled its differences with the Ministry it should turn seriously to the setting of its own house in order. The present discontents revolve around the burning question as to who should or should not be graded as specialists. It would be the rightful responsibility of the Joint Committee to publish its considered standards

in the matter, and to ask all assessment committees to review their gradings in the light of those standards.

I believe the present dissatisfaction would disappear if some such authoritative statement was made as to the qualifications of specialists; nor would it matter how high the standards were, provided they applied equally to everyone and were not altered in any way to suit any particular case.

As an illustration of what I mean, may I submit, with all due deference, that the Joint Committee should recommend and the assessment committees agree that no medical practitioner should be graded as a specialist unless

(1) In the case of the medical specialties he holds all three of the following qualifications—namely, (*a*) a doctorate in medicine of any university; (*b*) a fellowship of any Royal College of Physicians; (*c*) a specialist diploma granted by any university, faculty, or royal college;

and (2) in the case of the surgical specialties he holds all three of the following qualifications—namely, (*a*) a mastership in surgery of any university; (*b*) a fellowship of any Royal College of Surgeons; (*c*) a specialist diploma granted by any university, faculty, or royal college, the specialist qualification being in the case of obstetricians and gynaecologists either the M.M.S.A. or the M.R.C.O.G.;

or unless (3) he has had twenty years' experience in the actual practice of his specialty *in a senior capacity*.

As the hospital services developed, and the existing senior men retired, the number of specialists graded in group (3) would diminish steadily until eventually all specialists would be graded under either (1) or (2). Accordingly, it should be considered as essential for the future welfare and satisfactory progress of the hospital service that no medical practitioners should be graded as specialists under either (1) or (2) unless they hold, or until they obtain, *all three* of the fundamental qualifications specified for each of these groups.

I believe that some such scheme as this would be welcomed by the profession throughout the country as being concrete and definite, impersonal and just. If such a scheme was adopted and applied before the disputed gradings were confirmed it would banish at once and for all time those ugly spirits of suspicion and distrust which always appear when everything is dark and nebulous, secret and occult.

As we all know, in the latest issue of the "Terms and Conditions" the "specialist grade" has been omitted and a "consultant grade" introduced. It therefore becomes all the more important to ensure that the prestige of our consultants is not injured nor their quality lessened by the hasty and irregular grading of improperly qualified persons as "consultants."

As many of us are aware, provision has been made in the "Terms and Conditions" for the appointment of consultants "at age 31 or earlier." Generally, however, medical practitioners "at age 31 or earlier" cannot be expected to possess that wide experience which always has been associated with and commonly is required of those called "consultants," so that it seems to "old buffers" like myself that the careers of many promising young men and women might be damaged prematurely and unnecessarily by the invoking of this somewhat provocative provision.

There appears to be a case here for the reintroduction of the "specialist grade" for medical practitioners between the ages of 30 and 45, the title of "consultant" being reserved for specialists over the age of 45. If the Joint Committee were able to arrange this with the Ministry the old relationship and long association of specialists and consultants would be preserved, and incidentally assessment committees would be able then to solve some of their more tiresome problems.—I am, etc.,

SIC VOS NON VOBIS.

Grading of Hospital Staff

SIR,—I have been shocked by the many serious anomalies in the recent gradings and saddened by the apparent indifference of those more fortunate in what appears to be a lottery. Personally, I know six medical people who have been downgraded, so the condition must be widespread. They were all on the staffs of large voluntary hospitals before the Act, they were all freely elected to their positions, they all hold higher specialists' qualifications, and they are all recognized as specialists by their colleagues. Now they are made to suffer loss of prestige, and unless they are regraded they will suffer loss of income. They will certainly suffer unnecessary mental anxiety.

I am sorry to have noted throughout the whole of the recent business of regrading a certain meanness of behaviour on the part of certain regional boards. Roughly, all grading has been done by two bodies: (*a*) the groups of teaching hospitals, and (*b*) the regional boards. Those of us who serve on committees of both must be struck by the marked difference, not only in matters of grading, and have had pin-pointed the meanings of the words "profession" and "business."

I have called this grading a lottery; I am sorry to state that it is a dishonest lottery, for of the six cases to which I have referred three are graded as consultants by another board for exactly the same work and responsibility. What a farce. Fourteen days' leave to appeal is granted. This at the height of the holiday season, when there must be many who will not read of their downgrading until after this period has elapsed.

Now what are we to do? I write as one who was once proud to be a London specialist and who is now a National Health consultant. We must make our views known. We must speak with one voice. Injustice to a colleague affects us all. I know that a good doctor is a busy, tired doctor and that it is an effort to write a letter. But in a welfare State we are paid by the hour, and our prestige with our masters will not be in the hours of unpaid overtime we do but how vocal we are. It is only in this way that societies, professional or otherwise, can know the feelings of their members.—I am, etc.,

London, W.1. EDWARD CAREW-SHAW.

SIR,—I consider that the letter of "Quousque Tandem?" (*Supplement*, Aug. 6, p. 76) urging the lifting by the B.M.A. of the veil of secrecy which has hung over the whole apparatus of grading is a matter on which individual consultants and medical staff committees should press their local representatives to take action.

So far the B.M.A.'s Central Consultants and Specialists Committee appear perfectly content to allow some 50% of those whom they have been elected to represent to be professionally degraded and financially ruined without a murmur of public protest. At first the chairman advised consultants not to sign any contracts proffered, but now, because certain other matters such as arbitration have been adjusted, contracts are to be signed without a fight being put up on behalf of these unfortunates.

Unless we find leaders with the courage to fight our battles instead of giving them away we are doomed to sink lower and lower into the mire. Even now really vigorous action by the B.M.A. could save the situation, but if this is not forthcoming I hope every down-graded specialist or consultant will attend every business meeting of his B.M.A. Division and Regional Consultants and Specialists Association and there work unceasingly with the support of all the fair-minded amongst the favoured few who are now consultants for the overthrow of our present leaders and their replacement by men we can trust not to let us down again.—I am, etc.,

Taunton. R. F. WINCKWORTH.

Conduct of the A.R.M.

SIR,—The conduct of the business at the recent A.R.M. left much to be desired. Much time was wasted on non-essentials, while reports of committees were rushed through with indecent haste. On the first day about half an hour was spent discussing the *Formulary*—all very amusing—but the time could not be spared; while at the end of the meeting reports of twelve committees were rushed through in less than fifteen minutes. For the finance of the Association we could not spare fifteen minutes at a time in the history of the Association when this subject merits the most earnest consideration.

The report of the Health Centre Committee, the result of two years' work, had no chance of being discussed. The result of this is that the Association still has no health-centre policy.

Members of executive councils have no yardstick by which to measure local authorities' proposals for health centres, nor can they have such a yardstick for another twelve months. They cannot tell the lay members what is the considered opinion of the profession on health centres.

It is admitted at the outset that the chairman of the R.B. had his difficulties as did the Agenda Committee, but the chairman of the R.B. is responsible for the conduct of the meeting. Members of that body would welcome a fuller appreciation by the chairman of the relationship between the time available and the work to be done. The members of the R.B. must be prepared to submerge their own pet speeches for the good of the meeting, and the chairman should try to sense the feeling of the meeting so that he will know when they have heard enough on a particular subject.

Now that the agenda has become so much bigger we must either spend more time or use the same time economically: the latter course will probably appeal to most representatives. In order to spend the time more economically it will be necessary to ration the time available. It is therefore suggested that a definite time should be allotted to each committee's report, to start at a definite time on a definite day, and that business not covered by reports should also be taken at a definite time. The standing orders should be amended to allow the time limit for chairmen presenting reports to be fifteen minutes, other speeches ten and five. It is agreed that we all must play our part in making our A.R.M. efficient.

The essence of good chairmanship of such a body as the R.B. is quite different from the chairmanship of committees or Council. It is to be able to know what the meeting feels and apply this knowledge rigorously and justly. The time must be rationed by the Agenda Committee. Time of speeches must be limited.—I am, etc.,

Birmingham. ARTHUR BEAUCHAMP.

Domiciliary Midwifery Service

SIR,—I am not altogether surprised that you find the Ministry of Health statement (*Supplement*, Aug. 6, p. 74) on the domiciliary midwifery service discouraging (*Journal*, Aug. 6, p. 328). At the same time you must agree that their recommendations are very similar to the recommendations of the B.M.A. in "A General Medical Service for the Nation," published in 1938, which you quote. The difference is one of emphasis.

Before my colleagues in general practice start shooting, I should like to indicate the right target.

(1) It is certain that there are not enough G.P.s in this country at present to carry out all the antenatal and post-natal examinations and confine all the women at present attended by midwives. There would seem to be sense in continuing to use antenatal clinics and midwives, while giving every patient a chance of seeing her doctor before and after labour. More, it is reasonable for the Ministry not to offer financial inducement to the doctor to be too free with chloroform and forceps in the second stage. Normal midwifery should surely be normal.

(2) A large section of the Royal College of Obstetricians and Gynaecologists hold strong views about allowing any G.P. to do midwifery. They are appalled by the danger run by a woman who engages a G.P. to confine her. In their view no one but a specialist should be allowed to treat any abnormality in midwifery. For them it is the midwife for normals and the specialist for abnormals.

(3) I know that the G.P. has a contribution to make to normal midwifery. The G.P., at least, realizes that we are just beginning to understand what normal midwifery should be like.

(4) There is nothing in this Ministry of Health statement which prevents a G.P. from taking full charge of his patients if he wishes. Some rivalry as well as co-operation with midwives, antenatal clinics, and maternity hospitals will do us no harm—in fact, will act as a spur.

Let us not be discouraged. We can show the others that our standards are higher, not lower, than theirs. We can prove our value to the community by our work, and in the end we might even persuade the Royal College that a G.P. can be a good midwife.—I am, etc.,

Cambridge. CLEMENT W. WALKER,
Member of the Maternity and Midwifery Standing Advisory Committee.

Financial Bond

SIR,—The members of the Consett Division feel that the profession should make a very earnest attempt to co-ordinate the action of all doctors, especially those in the general medical service of the National Health Service, and to this end they suggest that a fighting fund should be introduced not only to provide some financial backing to the profession as a whole but also to act as a sort of guarantee that the majority decision will be adhered to under all circumstances by those subscribing to the fund. They feel that unless doctors bind themselves together by some financial bond, unified action is almost unattainable, and they therefore suggest that all general medical practitioners should be asked to bind themselves together in this way.

It is tentatively proposed that subscribers be asked to make over some percentage of their N.H.S. fees—say 2–3% per annum—to the fund, and that they should forfeit these contributions if they fail to adhere to the policy as adopted by majority vote.

I have been instructed by the members of this Division to write to you in order that you may publish this proposal in the *British Medical Journal* with the object of stimulating some interest in this subject and of obtaining the reaction of the profession to such a proposal.—I am, etc.,

Lanchester, Co. Durham. B. S. ALDERSON,
Hon. Secretary, Consett Division.

Freedom of the Citizen

SIR,—Your correspondent, "Lieut.-Col., R.A.M.C." (*Supplement*, July 16, p. 51) at least knew who had made the decision that he would not be "embodied." I merely received this information on a form from the Labour Exchange, and until I read his letter I was not aware that local medical committees had sat in judgment on us and decided our fate. Like your correspondent, I have given a large portion of my life to voluntary service in the Army, and continue to devote a great deal of my spare time to the training of the unit I command.

Now it appears that some committee of medical colleagues has decided, with no reference to me whatsoever, that I shall not be allowed to serve with my unit in the event of a future emergency. Apart from its discourtesy, this is an intolerable interference with the liberty of the subject. Further, unless prompt action is taken to rectify blunders of this nature, the effects on the undernourished Territorial Army, which is already causing great disquiet, are liable to have fatal consequences. But perhaps the powers that be are not really interested in the form of voluntary endeavour that the Territorial Army represents.—I am, etc.,

NOT TO BE EMBODIED.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Dehton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 27 1949

GOETHE, AN APPRECIATION

BY

Sir CHARLES SHERRINGTON, O.M., G.B.E., F.R.C.P., F.R.S.

A cultivated public our civilized world over is now celebrating the bicentenary of the birth of Johann Wolfgang von Goethe. It would be difficult to find a happier event for commemoration. It had become Germany's turn for a literary heritage. America was still a stripling; the East was for Europe still a region partly fabulous. Our own continent rang the changes on itself. In *belles lettres* France and ourselves divided the honours. In our own case an era had supervened when the heroic couplet was supreme; even Homer's rush and flow were subject to it by the skill of Alexander Pope; and Thomson's *Seasons* offered a rural counterpoise to it with a commanding Continental following. Then it was that the German tongue in literature began to be heard—Herder, Schiller, and, as its head and front, Goethe.

Looking back in 1824, Goethe wrote, "I was fortunate. Shakespeare had left in English nothing else to do; but in German I soon got in front of what there was." The new era hailed not from Vienna or Berlin but from a provincial Court, Saxe-Weimar. It brought an engaging air of freshness; it derived from native springs. In some respects it had cousinship with ourselves, Burns, and the Percy *Reliques*. As an invasion it was transient, but its result was lasting. It affected Coleridge but touched little if at all the Romantics—Keats and Shelley and Wordsworth. Byron did not react to it, though it reacted to him. Its influence, of course, had in foreign travel to meet the drawback of using an alien tongue, and that difficulty was enhanced by a further circumstance—that the spear-head of the invasion came in the form of the lyric, and the great lyric is especially refractory to translation. It is often in short lines employing rhyme and a condensed felicity which ... yet be simple. As examples, and taking recourse to ...ory and to comparison, "Wer nie sein Brot mit Thränen ass," runs with "Fear no more the heat o' the sun"; and then again, "Liebchen, kommen diese Lieder jemals wieder dir zu Hand?" runs with "Who is Sylvia, what is she?" or de Musset's "Elle était belle, si la Nuit." The word-music is so wedded to the sense that no other words will do. Its audience is limited therefore to a native audience consisting of those to whom its language is their home tongue, and to a relative few outside that circle. Shakespeare's songs illustrate this and so do Goethe's *Gedichte*. Their native magic is incomparable, but it is not for export. This is a strong plea for a common language. The old monkish chants were in Latin. Esperanto? No, no; not until Esperanto has been lived in, laughed in, wept in, rejoiced in, sobbed in, can it be an adequate vehicle for a great lyric. Will such a day ever dawn?

Of all the major works of Goethe, I should suppose the dramatic poem, *Faust*, Part I, is the one most read to-day. I once visited the exceptionally complete Goethe library at Yale, and an impression which I received there was that of all his works *Faust*, Part I, is that which has called for most editions. It suffers somewhat less as to width of audience from the translation difficulty than do the lyrics. The story's general outline is so well known that even a reader not fully skilled in German can open it practically at any page and pick up something of the beauty of the text. We in English have the added zest of the echo of Marlowe's *Faustus*: "Was this the face that launch'd a thousand ships, and burnt the topless towers of Ilium? Sweet Helen, make me immortal with a kiss!" As imaginative poetry those lines are scarcely to be excelled, but Goethe's *Faust* is far richer in sustained intellectual dialectic. It is a poem in drama rather than an acting play: it is, however, given on the stage, especially in Germany, where it has the added appeal of being German. In it Goethe is thought to have succeeded in characterization better than anywhere else in the young girl Gretchen of Part I. Perhaps it is a pity that we readers should be asked to find a continuation of her in the somewhat wearisome Helen of Troy of Part II. Goethe is at his weakest in this respect in Part II. Of course he was when composing Part II already an aged man. As to the other *personae* of Part I, the restraint exercised in the delineation of Mephisto is a notable inspiration, a sort of mischievous "God's ape," too aloof for delight in the cruelty of what he does—a rebel against heaven, but of the meaner class. Anything more remote from Milton's Satan is not to be conceived. *Faust*, Part I, also instances what is not frequent in Goethe, humour—the garden scene with Martha.

As we think back to Goethe's masterpieces they strike us by their variety. During much of his career he was a literary sounding-board for the Europe of his time. *The Sorrows of Werther*, is a case in point. It has, I suppose, passed over into unreadability. But a romance which once took the reading world by storm cannot be altogether devoid of lasting merit. It reflected wholesale the sentimentality of a period when society lived on the brink of war, when domesticity in woman was a universally admired virtue and middle-class domesticity yearned for the romance attaching to the class above it. Sentimental romance is sadly at the mercy of satire, even from the good-natured. In halcyon times which we now call Victorian, Thackeray rallied the dear high-waistcoated Charlotte of Goethe. He remarked that even after her lover had killed himself "she, like a well-conducted person, went on cutting bread-and-butter." Goethe in his later years said that in Werther he was like the pelican drawing blood from his own breast. Is there not a Werther period in most young men, even to-day?

by the classical signs. In some cases it resembled pneumococcal meningitis. The cerebrospinal fluid was usually frankly purulent and the organism could be recovered from it. But the fluid may be clear, with only a lymphocytic reaction and a raised albumin to suggest the possibility of meningitis. In three cases the cerebrospinal fluid was normal in all respects, although severe suppurative meningitis was revealed at necropsy. Of the 25 cases only four were cured, and four became chronic.

Cure seems to be possible only in cases that are treated promptly: two who were eventually cured were treated when the cerebrospinal fluid was still clear and showed only an increase in lymphocytes and albumin. If treatment is insufficient or too late the patient may die or the disease may become chronic and hydrocephalus may appear. One of our patients, on whom we had decided to operate, developed hydrocephalus. A ventricular puncture revealed at first a clear fluid, which became opaque at the end of the aspiration and was found to contain *Bact. coli*. These findings precluded further intervention. These cases of hydrocephalus are rapidly progressive and call for operative treatment, but we have not yet seen a case in which this has been successful.

tivity of the organism *in vitro* and the clinical progress of the disease. We have proved this by centrifuging in five cases the clear (and therefore apparently sterile) tubes and culturing the deposit on agar. Although the five cultures originally appeared to be sensitive to concentrations of streptomycin of 1 γ, 10 γ, 20 γ, 40 γ, and 200 γ, respectively, it was demonstrated that the newly cultured organisms were still living and could grow in media containing 10 γ, 50 γ, 20 γ, and 500 γ of streptomycin. The organisms had therefore not been destroyed, but their development had been inhibited. The sensitivity of the organisms varied greatly from case to case, according to whether they were recovered from the urine, the blood, or the cerebrospinal fluid. The sensitivity of those affecting the meninges is obviously the most important.

It was not possible to estimate the resistance of the organisms in all our cases, but our results show that there is no clear relation between the resistance of the organisms and the clinical progress of the case. The progress of the patient is determined not only by his response to streptomycin but also by anatomical lesions and the obstruction they present to the diffusion of antibiotics. This is, in our opinion, the reason for the difference between the relatively favourable prognosis in cases with septicaemia and the extreme gravity of those with meningitis. All the necropsies on cases of meningeal infection have shown a purulent arachnoiditis at the base of the skull which was almost always associated with marked ventricular distension whether there was clinical hydrocephalus or not. It does not seem to us that these lesions acted by the simple

mechanism of producing ventricular block, but it is certain that they affected the circulation of the cerebrospinal fluid and the diffusion of streptomycin injected subthecally.

Comment

We cannot close this paper without remarking on the relative frequency of infection by intestinal organisms in infants. In many circumstances saprophytic organisms in the digestive tract of the newborn become pathogenic and produce bacteriaemia, septicaemia, and meningitis. It is significant that in 18 months we have been able to observe in the Clinique Médicale des Enfants 41 cases of this type of infection, 25 of which developed meningitis. The signs of these infections are often obscure at first sight, and many of the cases can be discovered only by the careful examination of infants suffering from toxaemia and subacute fever with alimentary disturbances.

A search must be made for the organism in blood, marrow, stools, urine, pus from the ear, cerebrospinal fluid, nasopharyngeal secretions, and pus from any metastatic suppuration in the skin. Repeated blood culture is extremely important. The occurrence during a gastro-intestinal illness of an inexplicable alteration in the patient's general condition or, as we have shown, a polymorphonuclear leucocytosis, is a diagnostic sign of great importance. The possibility of meningeal infection must always be considered, and lumbar puncture, repeated if necessary, must be done as a routine measure. At the same time it must be remembered that the cerebrospinal fluid may be normal or be little changed.

Summary

An account is given of 41 cases of infection in the infant by intestinal organisms, seen over a period of 18 months. Of these cases 16 had septicaemia alone and 25 developed meningitis.

The clinical features of the condition are discussed, and an account is given of treatment with streptomycin given by the intramuscular, oral, intrathecal, and intraventricular routes.

A method of assaying the sensitivity of organisms to streptomycin *in vitro* is discussed.

The family allowances scheme has now been in operation for three years. The Ministry of National Insurance states that about 2,941,000 families of two or more children are receiving allowances varying between 5s. and £3 5s. a week at a total cost of £60 million a year. Family allowances are a payment of 5s. a week for every child after the elder or eldest below the age limit, which is usually 15 (school-leaving age), but is extended to July 31 following the sixteenth birthday where full-time education is continued and in cases of apprenticeship. During the three years the Ministry has received nearly three and a half million claims to family allowances, of which fewer than 100,000 have had to be rejected. The 2,941,000 families receiving allowances contain children within the qualifying ages as follows: two children, 1,850,000; three children, 688,000; four children, 247,000; five or more children, 156,000. The family drawing the largest allowance of £3 5s. a week consists of 14 children within the age limits. In the last year over 290,000 new claims to allowances resulted in payments for over 300,000 children. In the same period the total number of allowances in payment and the number of children for whom allowances are paid increased in each case by over 100,000.

STREPTOMYCIN TREATMENT OF INFANTILE DIARRHOEA AND VOMITING

BY

Crowley *et al.* (1941), in a survey of the literature and from their own findings, concluded that no single specific aetiological agent could be incriminated in infantile diarrhoea and vomiting. A wealth of facts relating to the clinical and metabolic changes arising in that condition has been accumulated and has made treatment more rational and effective; none the less, modern medical science has not yet provided the answer to the challenge of this illness. It is therefore not surprising that almost every chemotherapeutic agent introduced during the last decade has been tried in the treatment of infantile diarrhoea and vomiting in the vain hope that it might offer a satisfactory solution to the problem.

Recently streptomycin has been used and a number of encouraging results have been published. James, Kramer, and Armitage (1948) treated 30 children aged from 6 days to 13 months with streptomycin by mouth, on the basis of their finding in the stools *Proteus vulgaris*, to which they attributed pathogenic significance. They pointed out that some of their cases not associated with *Pr. vulgaris* also improved on streptomycin. There were no deaths in their series, and convalescence was particularly rapid. In a control group of eight cases *Pr. vulgaris* was isolated from the stools of five infants; all recovered, though at a slower rate. The total dose of streptomycin was 2 g., given over a period of seven days. No toxic effects were noticed, and *Pr. vulgaris* was rapidly cleared from the gut as a result of treatment.

Pulaski and Amspacher (1947) reported an epidemic involving 13 infants, three of whom died; the successful outcome in the ten who recovered was attributed directly to streptomycin. The dosage used in all the cases was 0.1–0.2 g. of streptomycin per kilogram of body weight by mouth for two to ten days. Loeschke and Cochlovius (1949) attributed recovery from infantile gastro-enteritis to streptomycin in 9 of 13 cases. They gave 25–75 mg. five to eight times daily by mouth. Their bacteriological findings were *Bact. coli*, *Pr. vulgaris*, *Pseudomonas pyocyanea*, and *Streptococcus faecalis*. A reduction in the number of Gram-negative organisms isolated generally followed the oral administration of streptomycin. Leisti (1947) recorded his results in 46 infants suffering from diarrhoea; 38 were full-term babies, eight of whom died; 8 were premature infants, all of whom recovered. Streptomycin was given in a dosage of from 40,000 units (40 mg.) to 160,000 units (160 mg.) intramuscularly daily for one to eight days. Goettsch, Cobley, and Mulloy (1948) obtained excellent results in 44 cases of parenteral gastro-enteritis. There were three deaths in their group, which they felt could not be attributed to failure of streptomycin. Their dosage was 0.5 g. intramuscularly and 0.5 g. orally for seven to ten days

In the present investigation special attention was given to the presence in the stools of a serological type of *Bact. coli* var. *neapolitanum* (abbreviated in this paper to B.C.N.) and *Pr. vulgaris*, the object being to correlate the clinical effects of treatment with bacteriological findings. Organisms of the *Salmonella* and *Shigella* groups were absent in this series of cases. Bray (1945), Bray and Beavan (1948), Giles and Sangster (1948), and Taylor, Powell, and Wright (1949) have all described this particular serological type of *Bact. coli* associated with a high percentage of cases of infantile diarrhoea and vomiting. Dr. C. Giles kindly placed at the disposal of one of us (G.M.) antisera and subcultures of his alpha and beta types of *Bact. coli*, from which our own antisera were prepared (the alpha type corresponding to B.C.N.). Full details of the bacteriological investigations and findings will be published later.

Stools were cultured before streptomycin was given and just before or after the end of treatment. No case was considered to be negative for B.C.N. until at least 30 colonies had been tested specially. The streptomycin sensitivity of B.C.N. strains was tested on plates, using strips of filter-paper soaked with 1 mg. per ml. of streptomycin.

Results of Treatment

Cases of non-specific infantile diarrhoea and vomiting admitted to hospital, as well as those developing the disease after admission, were divided into three groups. One group was treated with streptomycin by intramuscular injection, a second group by oral administration, while every third case, regardless of its severity, acted as a control and formed the third group.

Two standard schemes of dosage were employed for both the intramuscular and the oral route of administration. The first was to give 20 mg. of streptomycin per lb. body weight per day, divided into doses given at four-hourly intervals day and night for five to seven days; the second was to administer 100 mg. at four-hourly intervals for 24 hours and 75 mg. at four-hourly intervals for the remainder of the period, which varied from four to six days. The total dosage used for a single case therefore rarely exceeded 3 g. Five to seven days' treatment was regarded as adequate for assessment of failure or success.

All patients were given fluids, whether receiving streptomycin or not. The following fluids were used: plasma, blood, 5% glucose in N/5 saline, Hartmann's solution, 2.5% or 5% casydrol intravenously, according to the requirements of the individual infant. Feeding was started after 24 or 48 hours with a diluted skimmed lactic acid milk, gradually increasing the concentration of the formula if improvement was maintained. During the starvation period Hartmann's or Darrow's solution was given by mouth.

The clinical condition of each patient was classified as mild, moderate, or severe, according to the degree of dehydration, character of stools, persistence of vomiting, and initial loss of weight. The existence and the nature of parenteral infection were noted.

The effect of treatment was assessed by the clinical response. Some cases improved rapidly and recovered during the course of streptomycin treatment, and it was these which had to be considered as possibly benefiting from streptomycin therapy. Others showed no improvement during the period when streptomycin was given, but recovered eventually; these were considered not to have responded to streptomycin. Fourteen (19%) of the patients died.

Two levels of dosage have been mentioned, but as there was no apparent benefit from the higher dosage no differentiation has been made in analysing the results.

Table I sets out the number of cases, classed according to clinical severity and the response to treatment. The control group and the cases as a whole are included for comparison.

The details of individual cases are shown in Tables II, III, and IV.

Bacteriological Observations

Of the 79 cases in this series, B.C.N. was isolated from the faeces at the first examination in 50 (63%). It was more commonly present in severe cases (76%) than in moderate and mild cases (50%). The difference is statistically significant, as it is just over twice the standard error. Of severe cases in which the organism was found, 42% ended fatally (13 of 31 cases). In comparison, of the severe cases which did not have the organism 10% were fatal (1 of 10 cases). This difference is also significant statistically, being more than twice the standard error.

One may therefore conclude that in this series there was a significant correlation between severity of case and the presence of B.C.N., and also between the probability of death in severe cases and the presence of this organism.

* N.I. = Not improved, but recovered later on routine treatment. S. = Streptomycin-sensitive. R. = Streptomycin-resistant.

These findings may not, however, apply generally, and in themselves may not indicate a causal relationship.

The organism was often found in mild and moderate cases. It also persisted in recovered cases, even those which had been clinically severe. Of 50 recovered cases it was found in 27 (54%), which was a very small reduction compared with the initial incidence of 63% if a causal relationship existed.

About half the cases from which the organism was isolated before treatment yielded streptomycin-resistant strains (24 of 50 cases, 48%). Strains which were initially sensitive often became resistant during treatment, a change which was noted in 12 of 16 cases (Tables II and III). Five of these 12 cases recovered satisfactorily.

The findings as a whole may be regarded as not supporting an aetiological relationship of this organism to infantile diarrhoea and vomiting. They indicate, too, that streptomycin therapy had little effect in eliminating the organism from the bowel.

Pr. vulgaris was isolated initially in 10 cases, in 6 cases being associated with B.C.N. or the beta type of *Bact. coli*. Seven of the 10 cases were classified as severe. This organism appeared to have a minor significance in this series. It was not present in any of the patients who died.

Discussion

Our investigations confirm the frequent occurrence of a special type of *Bact. coli*, referred to as B.C.N., in the stools of infants suffering from infective gastro-enteritis, though this association was less common in our cases than in the series reported by Bray and Beavan (1948), Giles, Sangster, and Smith (1949), and Taylor, Powell, and Wright (1949). No evidence has yet been forthcoming to prove the pathogenic importance of any of the varieties of *Bact. coli* shown to be associated with infantile diarrhoea.

B.C.N. was isolated from 25 of 32 cases arising after admission to hospital; in all probability these were the result of cross-infection, a conclusion that was supported
